Morgantown—The plant and holdings of the Quality Cement Co. have been purchased by the Consumers' Coal Co., of Pittsburgh. The capacity of the plant is about 2500 tons a day. Charles Hout is the superintendent in charge.

The Sarepi Coal Co., which operates in the Red Stone seam, has completed construction work on a new tipple, new houses for miners and has just installed new equipment. F. J. Ice is the superintendent in charge.

By Nov. 1 the Clinton Coal Co., of whose plant J. S. Griffiths is general manager, expects to begin the shipment of coal. Construction work on a modern tipple has just been completed.

The Randall Coal Co., which has been operating a wagon mine, has converted its plant and with the installation of up-to-date machinery and the construction of a tipple has materially increased its capacity, now loading direct into cars. The company has also built a number of miners' houses. H. J. Elkridge is the superintendent of the company's plant.

The large Empire, or Davis, tract of coal in Monongalia County will be developed through the construction of 30 miles of railroad, to be known as the Indian Creek & Northern R.R., in the Indian Creek district of the county. The railroad will run from a point at the mouth of Indian Creek, connecting with Monongahela Ry., extending eastward along Indian Creek to Jake's Run, from that point to Dunkirk Creek and to Blacksville, Penn. The first mile of railroad will reach the first opening of the New England Fuel & Transportation Co. in the Empire tract, where the company will ship upon the completion of the plant there about 40 cars a day. According to present plans the first mile of railroad will be ready for operation by Dec. 1, construction work already having been begun.

Elkins—Since last March the Davis-Copen Coal Co., formerly the McCaa Coal Co., which has a large operation at Gilmer on the Coal & Coke Ry., has been engaged in trying to get its mines in shape for operation. At that time the Elk River rose 40 ft., completely flooding the mines and making the production of coal impossible during the summer. Pumps have been at work, therefore, for six months, clearing the mines of water. The mines are in workable shape now and about 65 men are at work. The company could use more men, but is unable to obtain them. As a precautionary measure and in order to guard against a recurrence of what happened last spring, the Davis-Copen Coal Co. has arranged for water locks so that there will be no further flooding of the mines. This company is headed by John T. Davis, of Elkins.

Madison—The shipment of coal from the plant of Mordue Collieries Co. has been begun. The opening of this operation represents nine months of construction work, ground for the plant having been broken early in December, 1917. The plant now in operation represents an expenditure of approximately $400,000. Since construction work was started six miles of railroad have been built, together with two miles of tramroad, and 100 miners' dwellings have been made ready for occupancy. Coal at the present time is being taken from two gas coal veins, one 5 ft. thick and the other 6 ft. thick. The company, however, expects to have its largest operation in the Dorothy vein, which runs from 10 to 14 ft. in thickness. When the plant is in full operation coal will be taken from seven different mines, giving the company a capacity eventually of 3500 tons a day.

OHIO

Straitsville—The new tipple at the Central mine of the Hocking Valley Products Co., replacing the one destroyed by fire July 13, has been completed and operations have been resumed. The mine is operated by the Hocking Block Coal Co.

ILLINOIS

Carlinville—Articles of incorporation for the Carlinville Coal Co. have been filed in the recorder's office. The company is composed of local men. A shaft is being sunk to supply the local trade. It has reached a depth of 60 ft. It is planned to have the mine in operation by Thanksgiving Day.

Belleville—The Executive Committee of the Twelfth Illinois District, United Mine Workers, has directed Secretary-Treasurer Walter Nesbit to purchase $500,000 worth of Fourth Liberty Loan bonds. The district organization already owns $500,000 of the previous issues. All of the locals in the district have bought and more than 90 per cent. of the individual miners have become bondholders.

Duquoin—What is said to be the largest mine tipple in the world is being constructed over the main shaft of the new mine of the Union Colliery Co., of St. Louis, at the new town of Dowell, five miles south of here. Coal is already being mined and sent to St. Louis for the use of the Union Electric Light and Power Co., of which the Union Colliery Co. is a subsidiary company. The mine has been christened the Kathleen Colliery, in honor of Kathleen McAuliffe, daughter of Eugene McAuliffe, president of the colliery company.

Edwardsville—The coal production of Madison County for the past twelve months, according to the report of John J. Fletcher, of Collinsville, County Mine Inspector, was 5,184,525 tons, an increase of 140,802 tons over the preceding year. Production at the largest mines in the county decreased, as follows: New Staunton Coal Co., 110,688; Mt. Olive and Staunton Coal Co., 131,907; Donk Bros. No. 1, 48,196; Donk Bros. No. 2, 135,050. Mine No. 1 of the Mt. Olive and Staunton Coal Co., however, made an increase of 170,240 tons, which was the largest in the county. There are 4653 men and boys employed in the industry, an increase of 410. There were 14 fatal accidents and 177 non-fatal accidents in the county during the year.

KENTUCKY

Madisonville—After raging for several days, a bad fire in the Circle City Coal Co.'s mine at Circle City was finally placed under control, it becoming necessary to seal up the mine.

St. Charles—The St. Charles plant of the St. Bernard Coal Mining Co. was put out of commission for three days as a result of a break in the machinery. Heavy rains and cold weather have resulted in a falling off in the labor supply in the Madisonville district.

Wolf Coal—The Ruthanne Coal Co., a Kentucky corporation, has taken over 1580 acres from the Wolf Creek Coal Co. at this place. The company is loading three cars a day, and output will be increased. J. M. Moore, of Charleston, is president, and B. J. Hener, of Huntington, W. Va., is secretary.

Pikeville—After being imprisoned behind burning mine supports for several hours, seven miners in the Big Hollow Coal Co.'s plant were finally reached by a rescue party, some of the men being unconscious when found. The fire started 50 ft. from the ground, from a gasoline fan engine exhaust, communicating to wooden supports, while the trapped miners were 800 ft. back, and couldn't be reached. They had just fired a ten shot charge and had the smoke from these shots also to contend with. The fire was put out without much loss.

WASHINGTON

Spokane—Development work has been started at Valley, 48 miles from here, by the Colville Valley Coal Co. The deposit is a sub-bituminous coal in a vein 6½ ft. wide, well defined and continuous. A shaft is now down 165 ft. and the company expects to be making shipments in a short while. F. Weatherwax is president of the company and A. N. Cantril, of Spokane, is secretary-treasurer.

Foreign News

Vancouver, B. C.—Stefansson, the Arctic explorer, states that the expedition from which he has just returned found several new islands and made scientific explorations of the country around Coronation Gulf. He confirmed the reports that copper and coal were found by him in the North, stating that coal was discovered on nearly every island touched by the expedition and predicting that these deposits would some day be found of great value.

Ottawa, Can.—Charles A. Magrath, Canadian Fuel Controller, has been appointed director of coal operations for Nova Scotia and New Brunswick with wide powers. He is given authority to make all necessary investigation respecting wages, holidays, hours of labor, utilization of labor to the best advantage and all other matters connected with the cost and production of coal during the war and for three months after the end of the war. The price to be paid for coal and coke produced in Nova Scotia and New Brunswick is to be subject to his approval and he is empowered to take possession of any mine or mining plant in those provinces and carry on operations.

Personals

I. C. Irwin has resigned his position as sales manager of the Rutledge & Taylor Coal Co., of Chicago, Ill. The position of office sales manager of the company has been abolished.

W. E. Brandt, formerly with the Thompson Coal Co., of Chicago, Ill., and recently with the district representative of the Federal Fuel Administration, has joined the Rutledge & Taylor Co.'s forces in Chicago.

Joseph C. Trevonow, of Elizabeth, Penn., mine inspector for the United Coal Corporation, has been appointed to the superintendency of the Jerome mines. Mr. Trevonow's successor has not yet been named.

Frank B. Collins, of Columbia, Ohio, formerly with the General Hocking Fuel Co., has accepted the position of sales manager for the H. W. Jenkins Coal Co. He is a brother of T. C. Collins, secretary of the Ajax Block Coal Co.

John F. Reynolds, general inside foreman of the Twinn Colliery of the Lehigh Valley Coal Co., near Pittston, Penn., a mining man of repute, has taken a position with the Associated Companies of Pittsburgh, a compensation insurance corporation.

W. J. Armstrong, manager of the crushing and pulverizing sales department of the Jeffrey Manufacturing Co., Columbus, Ohio, has recently received an appointment as Captain in the United States Army and has been assigned to the Ordnance Department in Washington, D. C.

R. Horne Smith, a leading financier of Toronto and a member of the Toronto Harbor Commission, has been appointed Fuel Administrator for Ontario, succeeding R. C. Harris. He refused to accept any salary. E. L. Cousins, engineer of the Toronto Harbor Commission, will act as his deputy.

William H. Brown, of Jerome, Somerset County, Pennsylvania, superintendent of the Jerome mines of the United Coal Corporation, has resigned, effective Oct. 1, to accept the position of general superintendent of the twelve Sunday Creek mines of the George M. Jones Co., with headquarters at Glouster, Ohio.

Payne G. West has been appointed as assistant manager of field sales for the Lakewood Engineering Co., of Cleveland, Ohio. Mr. West is a graduate of Carroll College, class of 1901. He later studied civil engineering for two years at the University of Wisconsin. In 1907 he became associated with the T. L. Smith Co., of Milwaukee. During 12 years with this firm—most of which he was assistant sales manager—Mr. West thoroughly familiarized himself with all branches of the machinery field as well as with factory production methods.

Industrial News

Binghamton, N. Y.—The C. H. Peters Coal Co. has recently filed notice of the dissolution of the company.

Syracuse, N. Y.—Due to the recommendation of E. N. Trump, engineer for the Federal Fuel administration, a total of approximately 60,000 tons of coal will be saved by thirty plants in this section.

Montour Falls, N. Y.—A. J. Barnes has been appointed export manager of the Shepard Electric Crane and Hoist Co., with headquarters at Montour Falls, N. Y. Mr. Barnes will also continue to be director of publicity.

Birmingham, Ala.—The production of coal in the Birmingham district showed a slight increase for the week of Sept. 9 over the preceding week, a total of 392,939 tons being mined as against 390,413 of the former week.

Philadelphia, Penn.—The Pennsylvania Railroad Co. has awarded a contract to the Roberts & Schaefer Co., Chicago, Ill., for the construction of a new 1000-ton capacity reinforced-concrete automatic electric locomotive coaling station at Perryville, Md.

Baltimore, Md.—A recent report from Pittsburgh announcing that the Baltimore & Ohio R. R. would devote its entire freight traffic to the transportation of coal has been denied by officials of the company. It was added, however, that coal would be the heaviest tonnage transported.

McAlester, Okla.—The Oklahoma Coal Operators' Association at its regular annual meeting at McAlester reëlected officers as follows: R. T. Price, Muskogee, Okla., president; D. J. Jordan, Oklahoma City, vice-president; F. F. McGrave, McAlester, secretary and treasurer; J. B. Kerr, McAlester, commissioner.

Connellsville, Penn.—The Western Maryland Railway Co., Baltimore, Md., has awarded a contract to the Price Construction Co., Maryland Trust Building, Baltimore, for the erection of a new local coaling station at Powest Junction, near Connellsville. H. R. Pratt is engineer for the company.

San Francisco, Cal.—B. H. Tripp, special representative of the Chicago Pneumatic Tool Co. on the Pacific Coast, has succeeded M. W. Priseler as district manager of sales for the Pacific Coast territory. His headquarters are at 627 Howard St., San Francisco. The Los Angeles branch of the company at 521 Title Insurance Building comes under Mr. Tripp's jurisdiction.

Joplin, Mo.—The Lightning Creek Coal Co. was incorporated under the state laws of Missouri and articles filed in Carthage, Jasper County, on Sept. 9, with a capital stock of $12,000. The incorporators are John R. Griggs, Pittsburg, Kan.; P. E. Tabor, Joplin; Mabel M. Bash, Joplin, and M. R. Lively, Webb City, Mo. A plant will be erected on the property at Pittsburg in the near future.

Chicago, Ill.—In order to provide increased facilities for manufacturing the Pneumatic rotary dump and other mining specialties, the Wood Equipment Co. has recently purchased and equipped commodious shops at Grand Crossing, Chicago. The main offices will be located at that plant and the company will continue to maintain city offices in the McCormick Building, as well as branch offices in New York, Pittsburgh, Knoxville and Denver.

Pittsburgh, Penn.—Three hundred steel coal cars, which secret service officials say were built by the Orenstein-Arthur Koppel Co. for secret shipment to Germany by way of Mexico, will be sent to France for use in coal fields recaptured by the Allies. The Orenstein-Arthur Koppel Co.'s plant near here was sold at auction recently by A. Mitchell Palmer, alien enemy property custodian, to the Pressed Steel Car Co., which will build 2000 more cars for the Allies.

Buffalo, N. Y.—It is announced that the local manager of the mine of the new Buffalo-Kanawha Coal Corporation will be James T. Lightner, an engineer and stockholder, who lives at Charleston, W. Va., a short distance from the mine, which is located in the Campbell Creek valley. The coal will be taken by the Campbell Creek Coal Co. Shipment has begun with an output of nearly 200 tons daily. George A. Corson, elected manager, will not leave Buffalo.

Cincinnati, Ohio—Receipt of 40,000 tons of coal at this market was accomplished by the arrival on an artificial wave of the Ohio of sixteen tows of coal, with a total of 90 barges, all loaded to capacity. All this fuel was allotted to Cincinnati concerns and will be distributed on the local market. The Campbell's Creek Coal Co., the Hickey Transportation Co., the Otto Marmet Coal and Mining Co. and the Pittsburg Coal Co. were interested in the shipments received.

Toledo, Ohio—Increased activity at the docks of Toledo was shown during the week ending Sept. 14, indicating a better movement of coal to the Northwest. The Hocking Valley docks during the week loaded 207,166 tons as compared with 227,253 tons for the previous week, making a total of 3,297,000 tons for the season. The Toledo & Ohio Central docks during the same week loaded 92,000 tons as compared with 66,000 tons the previous week, making a total of 1,449,000 tons for the season.

New York, N. Y.—H. W. McMaster, general manager of the Wheeling & Lake Erie R. R. at Cleveland, has reported to A. H. Smith, Regional Director of Eastern Railroads in New York, that the steamer "Colonel J. M. Schoonmaker" was cleared from the docks of that railroad last Friday (Sept. 20) with a cargo of 14,767 tons of Pittsburgh No. 8 coal in addition to its own fuel, amounting to 406 tons. According to the Coal and Ore Exchange this is the largest cargo of coal loaded on the Great Lakes.

Henryetta, Okla.—S. M. Barrett, secretary of the State Vocational Education Board of Oklahoma, will immediately arrange for resuming summer school work in the mining districts of the state. Under the supervision of the State and Federal vocational boards, night schools will be reopened in the mining districts, particularly in the coal-mining districts. Instruction will be given in various branches, but special attention will be paid to instruction in mining. Such schools will be opened at Coalgate, Henryetta and McAlester.

Harrisburg, Penn.—Is a workman an industrial accident victim if the ankle of his right foot has been broken while at work—if that right foot was part of an artificial leg? A regularly executed accident report has been received at the State Compensation headquarters from the Boland Coal Co., mine operators at Dunmore, setting forth that James McGarry, an employee, turned on his foot and broke his ankle while at work Sept. 4. The accident report further states: "This is an artificial leg, however, but he had to have same repaired."

St. Louis, Mo.—St. Louis and Mississippi Valley shippers, at a conference Tuesday, Sept. 17, at the St. Louis Chamber of Commerce, voted to ask a 20 per cent. reduction in the river rate as compared to the rail rate. The position was taken that it would be unfair to charge full rates, as is done on the great lakes, until the service is equal to that on the lakes. Theodore Brent, traffic manager of the Mississippi and Warrior Waterways section of the Federal Railroad administration, announced that the operation of the barges would begin Sept. 28. He announced that coal rates will not warrant two handlings, one by water and the other by rail.

Clarksburg, W. Va.—Impetus was given to the production of coal from wagon mines by the operators of wagon coal mines in Harrison County this week when a number of such operators formed a temporary organization by electing L. E. Dorsey chairman and E. W. Bell, secretary. Mr. Dorsey is one of the incorporators of the Clarksburg Domestic Coal Co. The meeting was called for specific purpose of organizing the owners and operators of small mines not only that there might be more regularity in submitting reports to the Fuel Administrator, but also to demonstrate to the Fuel Administration that these same mines, looked down upon by so many, are producing a large quantity of coal when it is considered in bulk, even though such mines are operated for the most part by farmers and other persons.

New York, N. Y.—M. F. Burns, president of Burns Brothers, has again been appointed chairman of the special Liberty Loan Committee of the Coal Trade for the Fourth Liberty Loan campaign which opens on Sept. 28. The vice chairman is Harry Peters, of Williams & Peters, and the Wholesale Committee consists of J. F. Bermingham, president, Delaware, Lackawanna & Western Coal Co.; Gardner Pattison, of Pattison & Bowns; J. W. Whiteley, of Whitney & Kemmerer; James A. Hill, Knickerbocker Fuel Co.; George M. Dexter, Dexter & Carpenter, LeBaron S. Willard, Willard, Sutherland & Co., and Robert B. Baker, of Sterling Coal Co. Committees representing the retail trade have been appointed in each of the five boroughs. Charles S. Allen, secretary of the Wholesale Coal Trade Association, is the publicity manager.

Charleston, W. Va.—Accidents in West Virginia mines during the month of August resulted in the death of 41 men engaged in the industry. The largest number of deaths in any county or counties was nine, Logan and Raleigh counties each having that many. McDowell County was next with eight. As has nearly always been the case, falling coal, slate and roof was responsible for more deaths than any other cause, the number of such deaths for August having been 17. Mine cars caused the death of eight men within the mines, powder explosions killing two, electricity four, motors two and mining machine one, all of such deaths being within the mines. Outside the mines one man was killed under a mine car, three were killed in a powder explosion, one was electrocuted and two were killed from miscellaneous causes.

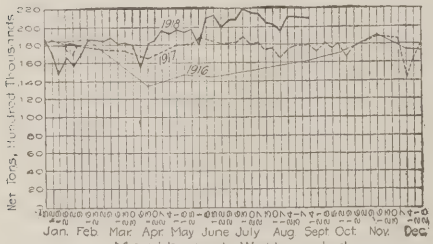
Sunbury, Penn.—The immense value of the millions of tons of coal deposited in Shamokin Creek as waste in years gone by was never better illustrated than in a law suit brought in the Northumberland County court in which a car of this anthracite is at issue. The claimants put its worth at $100, which makes the coal worth $2 a ton. Much of this coal is little larger than a pinhead, and smaller than a grain of rice. Thousands of tons are being taken from this stream daily, and 50 or more concerns are operating with a total of a half million dollars worth of equipment between Sunbury and Shamokin, a distance of 20 miles. Some of these "water miners" have cleared as high as $5000 on a single leasehold on abutting lands. Not more than ten years ago farmers were paid big sums for damages because coal was washed over their lands making it worthless for farming.

MARKET DEPARTMENT

Weekly Review

Coal Situation Dependent on Many Factors—An Increase in the Daily Coal Production Would Materially Aid War Program—Soft-Coal Output Improving—Demands for Fuel Increasing—Need for Conservation Emphasized—Trouble in Anthracite Region

CONJECTURES as to the outcome of the fuel situation are many, but only one gifted with infinite knowledge could prophesy with any degree of accuracy how the country will fare this winter with regard to its coal supply. The optimist points out that revised storage rules, modifications of zone restrictions, large stocks in the hands of consumers and an improved car supply at the mines are all happy auguries, while the pessimist shakes his head sadly as he compares the weekly tonnage figures with the estimated requirements. He heaves a sigh at the news of curtailments and labor troubles, and argues that the stress laid upon the need for rigid conservation is a certain indication of a stressful winter.



However, there is a happy medium—a middle course, as it were, between these two extremes. In spite of obstacles the output of soft coal has been maintained at the rate of 1,982,000 net tons a day for the period from Apr. 1 to Sept. 14. For the week ended Sept. 14 the tonnage mined reached 12,692,000 net tons, or 133,000 net tons greater than the daily average for the April to September period. An increase in the daily production for the rest of the coal year sufficient to wipe out the deficit of 13,624,000 net tons now existing would place the country at ease, so far as its soft coal supply is concerned. Conceding that this output is not possible—that transportation, inadequate man power and inclement weather will militate against maximum production—the soft coal mines should at least be able to maintain an average rate of production that would enable the successful carrying out of our war program.

The bituminous mines are indeed confronted with a stupendous task. Orders for munitions are piling up—and munitions mean coal. Translated into popular terms, one ton of coal is consumed in the manufacture of 27 three-inch shells. In the recent American drive at St. Mihiel alone approximately 1,500,000 shells were fired. Steel is only one of the many war industries dependent on coal, and when the demands of other war plants are totalled it can readily be seen why the line is being drawn more tightly around non-war industries, why production committees at the mines are doing all that is humanly possible to stimulate the miner to more regular working time and greater production, and why the Fuel Administration insists on the strictest sort of coal conservation.

During the week ended Sept. 14 the anthracite mines produced 2,088,000 net tons of coal, which brings the total output of hard coal for the coal year to date up to 46,566,736 net tons. After maintaining an enviable record for patriotism and production for months, the germ of discontent, fostered somewhat by union politics and Hun propaganda, infected about 30,000 hard-coal miners. These men struck for higher wages in the face of an existing agreement and the country's need, and as a consequence 26 collieries were forced to suspend operations. At this writing the critical aspects of the situation have passed, as the majority of those out on strike have returned to work while awaiting the decision of Fuel Administrator Garfield in regard to their plea for an increase in wage.

WEEKLY COAL PRODUCTION

Production of bituminous coal during the week ended Sept. 14, while considerably in excess of the week ended Sept. 7, due to the loss of time during that week on account of Labor Day, equaled the production during the week ended Aug. 31. Preliminary estimates place production during this week at 12,692,000 net tons, an increase over the week preceding of 13.2 per cent. and over the corresponding week of last year of 15.7 per cent. The average

daily production during the week ended Sept. 14 is estimated at 2,115,000 net tons, approximately the same as the daily average during the preceding week and considerably in excess of the daily average of 1,827,000 net tons during the week ended Sept. 14, 1917. The shortage for the coal year to date now amounts to 13,624,000 net tons and makes necessary an average daily production during the balance of the coal year of 2,379,000 net tons, or 2 per cent. in excess of the average daily production for the coal year to date.

Production of anthracite during the week of Sept. 14 is estimated at 2,088,000 net tons, 29.1 per cent. above the production of the preceding week, and 4 per cent. above the corresponding week of 1917. The daily average for the week of the 14th is estimated at 348,000 net tons against a daily average of 338,531 net tons for the coal year to date, and 334,290 net tons, the daily average for the corresponding period of 1917. Total production for the coal year to date is estimated at 47,733,000 net tons, an increase of 2.5 per cent. over the same period of 1917.

Shipments of bituminous coal during the week ended Sept. 14 from all producing districts not only exceeded the week of Sept. 7 but also the corresponding week of 1917. Material increases occurred in central Pennsylvania, where shipments amounted to 36,884 carloads as against 31,216 carloads during the week ended Sept. 7, in Ohio where shipments amounted to 28,216 carloads as against 22,455 carloads, and the district including Illinois, Indiana and western Kentucky where shipments amounted to 48,694 carloads as against 42,471 carloads.

A considerable increase occurred in dumping at the Lake ports during the week ending Sept. 14. Total tonnage (including vessel fuel) dumped at the Lake ports this week is estimated at 1,159,296 net tons, an increase of 14.5 per cent. compared with the week previous, and of 9.9 per cent. compared with the weekly average of July, August and September.

Beehive Coke—The production of beehive coke in the United States during the week ended Sept. 14 is estimated at 632,000 net tons as against 615,000 net tons during Sept. 7, or an increase of 3 per cent. The daily average during the current week is estimated at 105,000 net tons as compared with 103,000 net tons during the week preceding. The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production during the week ended Sept. 14 at 397,047 net tons and the operation of their plants at 77.8 per cent. of present capacity as against 76.2 per cent. during the week of Sept. 7. Yard labor conditions improved slightly during the week.

Byproduct Coke—The production of byproduct coke in the United States was further limited during the week ended Sept. 14 by shortage of labor in Pennsylvania. The operators of the country report production at 89.3 per cent. of their present capacity, as against 90.5 per cent. during the week ended Sept. 7. Of the total losses, shortage of coal amounted to 2.5 per cent., labor trouble to 1.9 per cent, repairs to plant 4.5 per cent., and all other causes, 1.8 per cent.

Maryland was the only state reporting material improvement during the week such improvement being attributed to better labor conditions. Operators in Illinois, Kentucky, Pennsylvania and Tennessee report decreased production. Operators in the states mentioned, with the exception of Pennsylvania, attribute the falling off in production to repairs to plants, while the decline in Pennsylvania was entirely due to shortage of labor.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended			
	Aug. 24	Aug. 31	Sept. 7	Sept. 14
Bituminous shipments, 123 roads	223,117	223,966	195,367*	222,519†
Anthracite shipments, 9 roads	40,865	41,281	32,234	40,699

* Revised from last report. † Subject to revision.

BUSINESS OPINIONS

Marshall Field & Co.—Current shipments for the week were well ahead of the same period a year ago. Road sales for immediate and also for spring delivery show a very good increase compared with the current week of 1917. The number of customers in the house was about the same. Collections continue good.

The Iron Age—Manufacturers of barbed wire were called to Washington to plan for quickly increasing output, after many weeks of restricted production. The en-

tire capacity, which is 50,000 tons a month, may soon be engaged. Besides American requirements a new call has come for 60,000 tons for Italy and 65,000 tons for Great Britain, and the latter amount may be increased to 90,000 tons. One Pittsburgh mill, on an urgent order for 80-lb. rails for France received on Wednesday, Sept. 11, rolled 20,000 tons before the end of the week. There is an entirely unprecedented volume of shell steel orders; sheets are wanted in large quantities for trench shelters and rolling kitchens, and in all ways the needs of the American army have been pressed upon the steel mills, until for one week the incessant call for ship plates has become an undertone.

Bradstreet's—Indeed, the movement of grain is of enormous proportions, the fixed price of wheat having superinduced heavy marketings and obviated fears of a receding market, heretofore a concomitant of large shipments. Bank clearings run to high figures in the zone outside of New York, more especially at centers where payments for grain and cattle have been heavy. Collections as a whole are good, though some complaint is heard about government payments being rather tardy, and, of course, the heretofore drought-stricken parts of the southwest are backward in making remittances. While the stock market continues dull, prices are relatively firm, and as extensive preparations are being made for the Fourth Liberty Loan, money for speculation is not available, which fact prevents noteworthy response to the very favorable war news received from all fighting fronts.

Dry Goods Economist—"Will the Government fix the price of raw cotton?" This question is being asked in all branches of the dry goods trade, manufacturing, wholesaling and retailing. Because of fear that some such action may be taken in an effort to stabilize the cost of cottons to the Government, to our Allies and to our own people, sales of raw cotton have decreased substantially and quotations have fallen off sharply. The wool situation is perhaps most tersely described in the announcement made early in the week that "There may be a supply of wool for civilian use next year." The explanation of the lack of wool is found in the announcement from Washington that 313,000 soldiers were started on their journey across the Atlantic during the month of August. It must be recognized that this great number of men could not have been transported had the vessels used in carrying them been allowed time for the shipment of west-bound cargoes. As a matter of fact, many of these vessels were unloaded and started back within 24 hours of their arrival on the other side.

American Wool and Cotton Reporter—The mill supply of wool has been conserved by the policy which many plants have adopted of using no more than was a necessity for ordinary cloth production. Although the outlook for manipulated fabrics is brighter, there are still many concerns which will not consider any large production of such fabrics. They believe that it will be safer to produce uniform fabrics at a moderate or small profit, and to hold the reputations which they have built up for over a period of years. Price-fixing is the principal topic of discussion before the cotton trade today. It is regarded by one manufacturer as perfectly feasible to fix the price of the staple, and he estimates that at least 95 per cent. of the trade would favor fixing differentials. It is felt by some that it would not be such a stupendous task as it is regarded by others, and is argued that if wheat can be regulated with its various grades that cotton can likewise be regulated. A price of cotton should be fixed sufficiently high to satisfy the South, and then the price of goods should be fixed so as to make it a reasonably profitable business.

Atlantic Seaboard

BOSTON

Falling off in receipts is more marked. Further embargoes issued in Central Pennsylvania. New car rating expected to be a benefit. Movement all-rail sags at the rate of 800 to 1000 cars weekly. Box cars come forward, but in diminished volume. Dispatch continues slow at Hampton Roads and obviously New England clearances are to be fewer the balance of the season. Baltimore shipments much reduced. New permissible reserve limits have little or no effect, the stocks in this territory having generally exceeded the former limits. Railroad fuel coming forward freely, but certain New England roads seem inclined to push off receipts. Effort made to increase flow of commercial coal via New York piers. Connecticut ports and those along Maine coast need emergency shipments. Anthracite receipts also fall off. "Independents" apparently do less than their share. Rumored that Storrow will distribute a given number of cars per day.

Bituminous—It is evident that receipts in New England will not again this season come up to the level reached in August. The discontinuance of shipments all-rail to a large number of steam-users and the release of steamers and tugs to other Government uses were bound to have their effect upon shipments in this direction, and there will probably not be another opportunity before next season for consumers promiscuously to get coal forward in liberal tonnages. At tidewater the change is particularly marked. Instead of steamers waiting in the stream to discharge there is a decided spot demand for cargoes and again occasionally there are idle berths waiting for steamers to arrive.

Embargo Notice No. 2 has been issued by the District Representative of Central Pennsylvania, of date Sept. 18. The pamphlet has 27 pages with names of consignees to whom shipments must be discontinued. How much this will reduce the all-rail movement to New England is difficult to estimate, for there are other factors in the equation. A large power plant, for instance, may not be embargoed, but yet the entire output of the mine ordinarily its source of supply may be commandeered for byproduct plants or other Government use important to the war program.

Inequalities in car distribution, it is felt, will soon be corrected to quite an extent in Central Pennsylvania. For years the rating for each mine has been figured according to the number of places in a mine rather than being guided by actual output over a given period. In other words, car rating has been apportioned on a basis of 100 per cent. labor supply and labor efficiency. In many cases this has resulted in some mines having empty cars regularly left over after a day's work and in others a deficit in car supply. This subject has now been carefully studied and after raising the question through railroad channels the district representative and the Central Pennsylvania Producers' Association were asked to submit a more equitable arrangement. This has now been done, based on the way operators have handled such cars as were furnished them. It is expected a much fairer distribution will be the result.

All-rail movement from the Central Pennsylvania district has sagged off from 4200 cars or so per week during August to less than 3200 cars during the week ended Sept. 14. Embargoes by the fuel authorities and the diversion of considerable tonnages of byproduct coal contributed to this slackened movement. Wagon coal has also decreased in volume, partly because most of the larger consumers now have satisfactory reserves and partly because of a strong demand from other territory. At one time the number of box cars weekly reached 1100, of which nearly 700 were absorbed by New England. Just now the movement from Central Pennsylvania in box cars is about 400 cars weekly. It is probable this will decrease rapidly now because of the demand to move other freight for which equipment has been lacking.

Hampton Roads dispatch shows no improvement, except as the number of steamers is reduced. Receipts from that quarter will show a decided falling off as compared with July and August, although official figures are not yet available. Certainly the peak for 1918 has been passed and consumers in this territory may regard themselves as very fortunate if they get more than a modicum on their contracts from now out. The volume of coal via the Curtis Bay piers at Baltimore has also been reduced, so that cargoes of "Storrow" coal from that port are much fewer in number.

Railroad fuel continues coming forward in good volume, especially all-rail. There is a disposition, however, on the part of certain of the roads to postpone full receipts, doubtless with the expectation that shipments will be as easy to get later as now. All the roads have been under a strain to get labor to unload coal and there have been such mixtures of quality as to make fuel agents most anxious about coal already in storage. There have been numerous cases of hot coal where plans to receive further volume deliveries have been more or less upset.

There is now a decided effort to get increased tonnages over the New York piers, particularly for Long Island Sound destination. There are also emergency requests from eastern points along the coast where delivery has to be made in small schooners or barges from New York. These are the areas in New England now most deserving of attention from coal distributors.

Anthracite—It is obvious also that receipts of domestic sizes are in the aggregate showing a decline. This is not so noticeable with the larger companies who are distributing along usual lines, but it is perfectly plain that "independent" shippers as a class are not making good their part of the program. They are having an eye to future business rather than to present obligations and here and there is a tendency not to ship the less desirable trade to whom they were eager to make deliveries a few years back. It is largely to fill in these holes that the larger shippers are now being asked to make emergency shipments of coal that would and should go to their own regular trade. It is now rumored that the New England Fuel Administrator is to have a given number of cars per day of "free coal" for distribution. This, of course, will not increase the movement for New England and it must be that Mr. Storrow feels his office can make better distribution than is now being made through trade channels. It should be remembered, however, that this coal is furnished by shippers of whom less complaint can be made in order to make up the deficiencies of shippers who are justly complained of. If this "free coal" could come from the latter it would be of distinct advantage.

NEW YORK

Suspension of mining appears to have had little effect on the New York market, although the companies affected report a falling off in receipts. Market getting down to a winter basis and receipts will assume a general average. Local conditions are encouraging and dealers look for better conditions than existed last winter. Demands for bituminous continue heavy, but there is little complaint heard.

Anthracite—The suspension of operations in many collieries in the lower anthracite regions last week had apparently little effect on local conditions, judging from the report of cars dumped here for the seven-day period ending Sept. 20, 6796 cars having been emptied as compared with 6635 the previous week, an increase of 161 cars. Receipts of coal by the companies whose mines were idle were reduced because of the failure of the men to work, but there was no complaining on the part of the trade.

Receipts each week now average about the same and as the cold weather approaches they are expected to settle down. There is not so much complaining of slow shipments and the trade appears to be in the same frame of mind concerning conditions that will exist here next winter, and that is that there will not be the shortage of coal that existed unless unforeseen circumstances occur.

Reports of production are not as encouraging as they might be. Lack of labor and petty labor difficulties in some of the mines are responsible for a falling off in shipments, which for the week ending Sept. 7 was reported as 1,617,579 net tons, a decrease of 642,137 tons from the previous week.

The Anthracite Committee has announced the lifting of embargoes on various towns in New England and has discontinued the sending of domestic sizes including pea coal, to 80 towns in Maine.

Local conditions are encouraging. Coal is moving freely and the trade is optimistic. None of the shippers have any domestic coal to offer to spot buyers, but there is plenty to meet the necessary demands of regular customers.

The steam coals are in good shape. Buckwheat No. 1 is reported plentiful by some shippers while others have nothing to offer. Most shippers have difficulty to find a ready market for their rice and barley supplies, but they are large enough to force a cut in quotations. Rice is in fair supply, while there is more than enough barley to go around.

Promises of increased allotment of coal for the Bronx have been reported, but warnings have been issued that the consumers there must conserve every pound of coal possible. Similar promises have been made to the consumers of Brooklyn and larger shipments are expected to begin to these two boroughs shortly.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

Circular	Individual	Circular	Individual
Broken..$6.75	$7.50	Buck...$5.10	$5.90
Egg.... 6.65	7.40	Rice.... 4.65	5.10
Stove... 6.90	7.65	Barley.. 4.15	4.30
Chestnut 7.00	7.75	Boiler.. 4.60	
Pea..... 5.50	6.25		

Bituminous—With receipts far too small to meet the demand conditions are favorable and there is no urgency for coal that goes unanswered. Everybody entitled to it has some coal and many consumers are reported to have good stocks on hand.

The revision of storage regulations announced last week enables many manufacturers to carry larger winter stocks. Consumers in southern New York and New Jersey on the preference list recently defined by the War Industries Board are now permitted to accumulate 60 days storage instead of 30 days. Those in Class 2 may carry 50 days storage; Class 3, 40 days; Class 4, 30 days, and those consumers not on the preference list are limited to 20 days storage.

Production figures are not encouraging. With the labor situation as it now is, and as it is likely to exist for the balance of the war, there is not much hope held out to the consumer. Local dumpings show a falling off of 353 cars for the week ending Sept. 20, as compared with the previous week 7277 cars having been dumped.

State Fuel Administrator Cooke has let it be known that replies received to the questionnaire sent out by him from 21 steam plants which consumed 628,315 tons of coal last year, show that with the improvements and repairs being made by their owners that 68,023 tons of coal will be saved a year, or 11 per cent. of last year's consumption. Altogether Mr. Cooke has received replies from 237 boiler plants in the nine southern counties of New York State, which include Greater New York, and says that if other consumers can do as well the supply of coal will be adequate, providing labor troubles do not suspend operations at the mines.

The car supply is not so good as it was a couple of months ago, but there is not much complaint because of the lack of labor. Some producers might find it hard to load a larger number of cars. Heavy stocks are being taken by the railroads but some shippers complain of the neglect of the companies to pay their bills. Demand for bunker coals continues heavy on account of the large number of vessels constantly coming into the harbor.

Current quotations, based on Government prices at the mines, net ton, f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite suspension creates anxiety. Public still much concerned. Higher retail prices seem likely. Further local regulations by fuel authorities. Orders not to be completed before Jan. 1. All orders to get some coal at once. City's allotment slightly increased. Steam trade extra active. All sizes sold up but culm. Bituminous unchanged. Car supply only fair. Coal well distributed under new plan.

Anthracite—The strike in the anthracite region hit this district particularly hard, as most of the mines concerned were those supplying a heavy proportion of tonnage to this city. The anxiety was by no means confined to the shipping and dealing interests, but the general public at the first sign of trouble flocked in on their dealers in droves and demanded the filling of their orders. As a result of this the few sizes that showed an inclination to lag were soon cleaned out, particularly egg, and the people forgot all about their preference as to sizes which they so tenaciously clung to all summer long.

In order to make every car of coal reach just as far as possible, the retailers have received instructions that in every case where two-thirds of a customer's order has been delivered they are not to try to make up the final one-third prior to Jan. 1 of the coming year. Of course, exceptions are made in the case of hospitals and the various charitable institutions. The dealers were not exactly surprised at this order, as they have felt for some time that it was the authorities intention that those people who have really received two-thirds of their allotment would be expected to try to make this reach over the entire coal burning season, which will not be so difficult if ordinary winter weather is experienced. All of the orders when entered were based upon the consumption for last winter, one of the worst on record, and there is a suspicion that in addition many of them were padded despite the efforts of the administration to check this evil.

To correct the confusion caused by the dealers receiving stop-orders from the order department of the fuel administration the dealers have been advised that they must not notify the customer that their order has been held until at least three days after the notice has been received. Previously such stop orders have often been withdrawn by the bureau and much confusion caused.

In order to prevent the accumulation of egg and pea coal in the dealers' yards the fuel administrator came out with the suggestion to the public that they accept a mixture of these sizes. It is claimed that while each size by itself is unfitted for use in both range and heater, by combining the two the result is very satisfactory. However, the suggestion came just at the time of the miners' strike and the dealers moved what little surplus they had without the least bit of trouble.

The city was in receipt of a cheering piece of news this week when the authorities announced that the quota for this territory had been further increased over the 18 per cent. allotment to 19.20 per cent. Shippers were notified that this increase was first to take effect in sections where deliveries are hardest in winter, such as Manayunk, Germantown, Chestnut Hill, Wissahickon, Olney and the northeast, and the increased tonnages for these sections are to be delivered to the dealers in September and October.

Following the mine suspension there was quite a flurry in the steam trade. Of course, there never was much of a slackening in buckwheat all summer long, but for several weeks past there was a tendency for rice and the smaller sizes to sag just the least bit among the larger producers. Coincident with the men stopping work inquiries for these sizes multiplied and at this time all sizes are in most active demand. Managers of industrial plants realize that the wage problem is not settled and as a consequence they are finding room for every car of almost any size of steam coal. Even culm shared in the demand to a moderate extent. The price asked for this fuel is generally held by the big shippers around $1.25, but we know of individual shippers in order to move large blocks are willing to shade this figure, although on single car lots are occasionally getting a little more.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—With the war industries on the new preferred distribution basis of a 30-day supply, all coal reaching this territory is being made to reach a wider area than ever. If it were not for the fact that the production is below expectations the situation could be considered satisfactory. There is really no definite improvement in the car supply, this phase of the situation being about as it has been for the past two or three weeks—probably an average supply running from 60 to 70 per cent. With heavy shipments going to lake ports, as well as New England, no appreciable increase in tonnage to this territory can be expected for many weeks yet.

The heavy fine recently imposed on a local shipping company for violation of the price order has created the greatest interest. The one query asked by many is why the purchasers of the coal at prices in excess of the Government figure have escaped punishment. There are also persistent rumors that other concerns are to be given an opportunity to explain apparent violations of the same kind.

BALTIMORE

Diversions of a better grade coal in box-cars noted. Supply continues liberal in regard to soft coal. Anthracite situation causing real worry, and retail organization issues an appeal to the public.

Bituminous—The rerouting branch of the fuel administration as it applies to this territory has made good on its promise to give some better grade coal to Baltimore to offset the almost unbroken run of dirty fuel that had been coming through to the dismay and discouragement of industries. The heavy proportion of box-car coal continues to come through, but business here does not complain so much of the extra cost thus involved when the coal runs of anything like fair grade. The better kind of wagon-haul coal in box cars has been diverted at the gateway scales from the Somerset region. The process of stocking up for short periods by industries here continues under the plan of holding down even the essential plants to a limited supply of fuel. The liberal run of coal here as to quantity is making the situation here easier day by day.

Anthracite—In the hard coal business there is real worry, however. As the weeks roll by, and the deficiency in the anthracite supply for domestic use grows more pronounced instead of being cleaned up by extra tonnage movement, both the fuel administration as represented locally and the coal trade sound warnings to the public. With the coal trade it is a mere reiteration of a warning that it has been giving for weeks to the fuel administration and the general consuming public. The fuel administration here the past week for the first time publicly admitted that its plan to have two-thirds of all orders in cellars here before winter was doomed to failure. At the same time an order was sent out by the chairman of the city committee of the local fuel administration directing that all consumers be given a little coal and that the two-thirds distribution move be discontinued. Word was passed to the trade that a limit of two tons should be placed on the deliveries now. This plan has not met the approval of the coal trade, where it is pointed out that it would not be fair to those with orders on the books for months to cut them off, after the fuel administration has allowed probably half the homes of the city the full two-thirds delivery. In an appeal to the public the Baltimore Coal Exchange shows that it has not abandoned the two-thirds plan. At the same time every effort will be made to give those absolutely out of coal enough to heat their homes during the first days of real cold weather, with the hope that better receipts here will enable further deliveries later.

Lake Markets

PITTSBURGH

Car supplies fairly satisfactory. Essential industries and byproduct coke plants well served. Dirty coal matter receives attention.

Car supplies to coal mines in the district are fairly satisfactory and on the whole reflect an improvement. Labor performance is fairly good, but could certainly be improved. R. W. Gardiner, production manager for the district under the Fuel Administration, is increasing his force for the inspection of coal. He states that complaints of dirty coal are chiefly in connection with wagon mines and stripping operations. Cases are being freely penalized 50c. a ton and decided improvement is expected.

The Pittsburgh district has just emerged from a period of rather drastic curtailment in the use of electric current from 7.30 to 10 a. m., necessitated by shortage of generating power on the part of the public service corporation, not on account of scarcity of coal. Officials of the Fuel Administration are elated over the prompt and full coöperation of the public and the experience indicates that if emergencies arise this winter requiring coal conservation there will be no slacking on the part of the public.

No definite time is yet assigned for the completion of lake shipments from the district, but it is practically certain that shipments will have to extend beyond Oct. 15. Essential industries are being fully served, including the byproduct coke plants, the only difficulty as to the latter being that stocks are not being accumulated to the extent desired. There are scarcely any open market transactions. The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, with 15c. extra allowed to be charged by brokers to consumers and retail dealers.

TORONTO

Cool weather finds many consumers without fuel. Plan for relief adopted by dealers and large deliveries suspended until all are supplied. Public advised to burn wood or other substitutes.

There is no marked change in the coal situation except that with the setting in of cool weather the demands of consumers who have not been able to lay in supplies have become more urgent. Many of the dealers are still refusing new orders. As

the result of a conference between the coal dealers, the city fuel controller and the Board of Control the dealers have agreed to suspend deliveries of large orders in hand until those consumers who are absolutely without fuel have been supplied. Those having no coal must forward applications in writing before Sept. 25, when they will be furnished with small quantities. A large number of applications have been received. The regulation allowing consumers to receive 70 per cent of their regular supply has been cancelled and the people are asked by the city fuel controller to burn wood or other substitutes so long as the weather continues mild.

Quotations for best grades per short ton are as follows: Retail anthracite, egg, stove, nut and grate, $11 to $11.50; pea, $10 to $10.50; bituminous steam, $9.25; slack, $8.25; domestic lump, $10.50; cannel, $13. Wholesale f.o.b. cars at destination, three quarter lump $7, slack $5.82.

BUFFALO

Quiet in bituminous, not active in anthracite, but much complaint of slow anthracite deliveries. Retailers refuse to take more orders.

Bituminous—The situation does not change materially, but it is plain that the authorities are not going to allow any surplus to accumulate anywhere, for the order goes out again directing curtailments in various directions. All jobbers report that they could sell more coal if they had it, but the supply is fairly good and the outlying territory appears to be accumulating some coal. If the war needs are not too great the supply will go around in some fashion, though it is plain that the coal will all be needed somewhere. If it is fairly distributed no distress should be experienced, though the concerns adjudged unnecessary will not get much.

Bituminous prices are still mostly made to consumers at the mines, but the delivered prices with all charges paid, are as follows: Thin-vein Allegheny Valley, all sizes, $4.65; Pittsburgh lump, $4.45; Pittsburgh mine-run and slack, $4.20; smithing and smokeless, $5.85; cannel, $5.60 to $6.10, all per net ton, f.o.b. Buffalo.

Anthracite—The situation is becoming quite strained. In spite of the promises of the fuel authorities and the fairly liberal allotment the supply has steadily run down, till the consumers are becoming alarmed. The retailers are refusing to book any more orders, saying that they cannot fill what they have. It is estimated, though, that about 95 per cent. of the coal needed is already ordered and the fuel authorities continue to say that the delivery will be made in good time. As it looks now it will mostly wait till the lakes close in December. If the daily lake movement of 100,000 tons is then turned over to the city the shortage will be made up in a week, and perhaps that is the plan, but the consumers see in the delay a prospect of continued shortage.

CLEVELAND

Bituminous is moving to the Northwest in record-breaking style, each succeeding week seeing the movement up the Great Lakes heavier. Suspension of shipments of Ohio and western Pennsylvania coal to the Michigan peninsula has served to increase both the tonnages available for the lake trade and industrial and retail consumers.

Bituminous—The heavy inroad Labor Day made upon coal production in the No. 8 district of southern Ohio is shown by the latest report of the Pittsburgh Vein Operators' Association of Ohio, which is for the week ended Sept. 7. In that week operators belonging to the association shipped 4408 cars, divided as follows: 2571 to the lake trade, 896 to Ohio, 661 for railroad fuel, 174 for Michigan and Indiana, and 106 for Canada. In the week ended Aug. 31 the carloads of coal shipped totaled 8876, which shows the loss Labor Day week was close to 50 per cent. Some Indiana and Illinois coal is coming into the state for railroad fuel, operators say, which is increasing the tonnage for the lake trade. The Pittsburgh Vein Association's most recent car supply report is dated for the week ended Sept. 14, and it shows the shortage for the week averaged 15.47 per cent. The shortage of 1298 cars in the week resulted in a loss of 64,900 tons. The railroad rating of the operators reporting is 8391 cars and the number of cars supplied was 7093. On the whole, recently, car supply has been good, much better, in fact, than labor. Registration day was almost wholly lost in many southern Ohio mines, and now county fairs are a diversion. Shipments to retail dealers have increased somewhat, though dealers' needs are by no means being met. Householders seem over-eager to store for the winter. Industrial plants are in the market for all the bituminous they can obtain, but operators are hewing close to the storage-limit line.

Lake Trade—Beyond all shadow of doubt the movement of bituminous to the Northwest via the Great Lakes is at its best so far this season. In the week ended Sept. 14 the lake fleet loaded 1,114,923 tons, not including bunker coal, at lower lake ports. In the first 15 days of September, which includes Labor Day, three Sundays and registration day, the fleet loaded 44,305 cars, which is about 2,000,000 tons. Coal is coming forward to the lower lake ports rapidly and the lake tonnage to take it aboard is immediately available. The prospects for moving the Northwest's quota grow brighter steadily. Detailed figures just put out by the Coal and Ore Exchange, Cleveland, which is conducting the lake traffic pool this season, show that up to Sept. 1 a total of 16,833,638.04 tons of bituminous was loaded at the lower lake ports, of which 16,089,511.94 tons represented cargo fuel and 744,126.10 bunker fuel. For the various months to date the loading of cargo and bunker fuel combined has been: April, 868,852.64; May, 3,194,198.10; June, 3,539,352.30; July, 4,234,305.05, and August, 4,996,929.95. The August loading was divided into 4,805,710 tons of cargo coal and 191,219.95 tons of bunker.

DETROIT

Need of larger supply of domestic coal becomes more evident. Steam coal users object to Illinois and Indiana stock. Lake movement active.

Bituminous—Continuance of cold rains and chill weather makes more impressive the insufficiency of Detroit's supply of domestic fuel. Homes are being made uncomfortable by weather conditions and in many instances the householders are deterred from warming their homes, either because they have no coal or because the scanty supply at hand renders them apprehensive that were they to consume part of it now, they may find themselves without fuel when even colder weather comes.

Stocks of bituminous coal suitable for household use are not being increased to any marked degree. Some retail dealers say they are unable to fill orders, unless customers will take mine-run, which is not adapted to use in hot air furnaces. Shipments from the Ohio, West Virginia and Kentucky districts which are now restricted for retailers, and to use of gas and byproduct plants and railroads are said to show a somewhat larger proportion of prepared sizes than earlier in the season, though as a whole the movement is described as of lesser volume, due to the limited market for slack and mine-run and to the continued operation of the priority order relative to lake coal.

Consumers of steam coal show much reluctance to stock up with the coal from Illinois and Indiana mines to which they are restricted by the order of the Federal Fuel Administration. Jobbers say the coal coming from those districts is of an inferior quality and that the more desirable product of the mines is being retained for home consumption.

Anthracite—Receipts of anthracite coal in Detroit to Sept. 19 approximate 25,000 tons, contracting with about 31,000 tons for the entire month of August. Retailers have practically no stocks on hand and in filling orders from owners of base-burners, which have priority over all others, are dependent for the most part on day-to-day shipments. Baseburner owners are allotted a maximum of three tons and until all have been supplied whose orders have been placed with dealers or the fuel administration, the other consumers must wait.

Lake Trade—During the week ending Sept. 14 a new high record was made for the season in loading bituminous coal for lake movement, the docks having dumped 1,114,832 tons, exclusive of bunker coal. The volume of shipments is being fairly well maintained through the present week.

COLUMBUS

Still a softness in the market for small sizes, due to the continued embargo against shipping screenings into Michigan. Domestic sizes are in good demand and a heavy tonnage is moving to the lakes for shipment to the Northwest.

The principal feature of the coal trade in Ohio is the continued softness in screenings, which has caused the Ohio Administration to modify its orders concerning storing on the part of large steam users. The prohibition against about 700 concerns in Ohio has been removed temporarily in order to absorb the larger amount of screenings on the market. Domestic and lake trade are both active. The domestic situation is generally considered satisfactory.

The lake trade is being pushed as much as possible in order to secure the required quota for the Northwest before the close of navigation. As a result special pains are being taken to move vessels and the movement is generally efficient. Reports from the Northwest show that there is no congestion on the docks and the interior movement is active. Lake prices continue firm.

The domestic trade is now attracting considerable attention. Retailers have a good run of orders and are making deliveries rapidly. They are receiving a fair proportion of the tonnage required. Reports in Columbus show that fully 65 per cent. of coal for private use has been stored by consumers.

Production is rather good although labor shortage is curtailing the output at many of the mines. Car shortage is also having its effect and on the whole the outlook is not encouraging. It is estimated that the output in the Hocking Valley and Pomeroy Bend districts has been about 70 per cent. during the past week. Eastern Ohio produced about 65 per cent. and the same figures are reported from Crooksville and Cambridge.

CINCINNATI

Cool weather has stimulated demand, while modified storage regulations have also helped movement. Car supply remains fairly good, and shipments continue heavy.

Frosty weather, following a period of cold and rain coming unusually early for this section, resulted in more active demand for coal for heating, domestic consumers, office buildings and others requiring fuel for this purpose for the first time during the season. At the same time the industrial demand received a direct stimulus in the shape of a removal of the restrictions formerly placed on the storage of coal by Washington, an increased supply being allowed under the regulations announced. This change enables industrial consumers to use more coal than they were at first allotted, as far as a reserve supply is concerned, and large dealers and operators at once received rush orders indicating the intention of these consumers to take advantage of the Government's permission.

While there has at no time been any difficulty on the part of the trade in placing all available coal, the increased demand resulting from the regulations referred to is gratifying, making it certain that business will continue steadily at its present high level. Nothing has occurred, however, to change the practical certainty that demand will run ahead of supply as the season advances, especially in view of the limited ability of the railroads to forward coal. In spite of the protestations of transportation officials, there is little doubt that the principal reason for the prospective shortage of fuel, as compared with consuming requirements, is the apparent inability of the railroads to place and move a sufficient number of cars to take care of the maximum production of the mines. The car supply is fair, but nothing like 100 per cent.

LOUISVILLE

Domestic demand lighter and dealers making first surplus accumulations of season. Steam demand good, but checked by fuel administrator. Better movement of eastern Kentucky coal to Louisville. Production about the same.

While there has been some improvement in the number of domestic orders handled during the past week, the heavy stocking appears to be over with except on orders held up for eastern Kentucky coal. At present the domestic demand is largely for one and two ton lots. A better supply of eastern Kentucky mine-run, as well as lump and screenings, is coming on this market, several retailers being able to secure a little of the grade.

The Fuel Administration is beginning to hold back deliveries to steam consumers, regulating them to the supplies as announced some weeks ago. Mining companies and jobbers have been forced to hold up numerous orders placed some time ago, and upon which only partial deliveries have been made. Present stocks must be reduced before further deliveries can be made. However as a whole the steam demand is active, although no heavy stocking can be done.

For the first time in many months some of the local retailers have been receiving

more coal than consumption is taking care of, with the result that yard stocks are improving and a few concerns have a slight surplus. Yards have been empty all season, and at the present time a number of dealers are more anxious to lay in surplus stocks than to make deliveries.

Conditions at the mines show little change. Eastern Kentucky is getting an erratic supply of cars, but about 50 to 75 per cent. regularly. Much better care is being taken of eastern Kentucky mines than those in western Kentucky, in an effort to move coal to the Northwest and Lakes. Western Kentucky is getting a 33 to 40 per cent. supply. However, labor is generally so scarce that the small car supply isn't making the customary difference. Considering the number of men employed production is holding up remarkably well.

BIRMINGHAM

Steam trade easy. Domestic demand brisk. Production lagging, and little improvement, if any, over previous week. Labor shortage, and in some instances lack of adequate car supply holding production far below normal.

Inquiries in trade circles elicit the information that the steam coal market is in a much easier condition now than for several months past, some rail lines having accumulated a 30-day stock, and consumers generally are in a more comfortable position as regards fuel. There is ample business being offered and in hand to prevent the accumulation of any surplus at the mines, however, and the daily output is being moved promptly when cars are in hand.

The foregoing is not true in the domestic channel, however, and there is a persistent and unabated call from the dealer, and in turn from the consumer. Receipts are fair considering operating conditions and transportation facilities, but there is no accumulation worth mentioning in the yards.

A number of mines on and immediately adjacent to the Warrior River are being badly handicapped in operation by the temporary suspension of the barge lines to New Orleans, Mobile and other port markets pending the transfer of the equipment to government control and operation. The Bamford mines, located on a branch of the Southern Ry. near Bessemer, have resumed operation after an idleness of many years.

Coke

CONNELLSVILLE

Slightly heavier production. Probable effect of new draft. Efforts to improve coke quality.

The Connellsville region is doing a shade better, both in making coke and in shipping coal for byproduct purposes. Labor performance is a trifle more satisfactory, but fears are entertained as to the effect of the new draft. Apparently this will effect some realignment in labor conditions. It ought to insure better performance on the part of miners and such oven labor as may be held to occupy "key positions," as they will lose their industrial exemption if they do not work faithfully, while on the other hand the ranks of common labor may be reduced.

Following the Fuel Administration's order effective Sept. 16, prohibiting the screening of old dumps at beehive coke works to regain coke for household use, the matter was taken up by interested parties with the Fuel Administration, resulting in an agreement whereby the operation will be placed under closer surveillance, waste of labor will be avoided and the price limit will be reduced to $5.50, the screen being reduced from ⅞ in. to ½ in. Tailings, if entirely free from dust and dirt, will be salable at $3, but it is probable that some contracts will not attempt to prepare the tailings at all. Box cars are to be used exclusively.

The Fuel Administration continues its efforts to bring about the production of better quality coke. Furnaces insist it is quality of coke, not quantity, that is interfering with full production of pig iron. Some comparisons made indicate that the furnaces in blast are producing about 3,000,000 tons a year less pig iron, or 7 or 8 per cent. less pig iron than their capacity, as indicated by past records when fewer furnaces were in blast, and the major portion of the loss is attributed to the quality of the coke available. The prevailing opinion seems to be that operators and coal miners are about equally to blame. The least increase in the amount of slate, etc., mined, decreases the output of pig iron by increasing the ash in the coke. There is practically no open market, except for foundry coke. We quote: Furnace $6; foundry, 72-hour selected, $7; crushed, over ⅞-in., $7.30; clean screenings from old dumps, over ½-in., $5.50, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Sept. 14 at 348,130 tons, an increase of 3110 tons, and raw coal shipments at 216,185 tons, an increase of 12,467 tons.

Buffalo—The trade is steady and sufficient with the combined output of local byproduct and ordinary beehive ovens. Local jobbers sell quite an amount of the low end of the byproduct coke at regulation prices, mainly for fuel, which run at $4.34 to $7.68 for various sizes. Most jobbers do not go into the trade, as they cannot get the foundry and furnace coke. The movement of iron ore is still heavy, being to Buffalo 1,561,149 gross tons for August and 5,434,980 tons for the season to September. The entire amount received by the nine Lake Erie ports was 7,736,791 tons for the month and 29,633,200 tons for the season.

Birmingham—The demand for coke in the local market is strong for both furnace and foundry grades, but the supply is woefully short. Production at the ovens has been far below normal for several weeks past, labor troubles, and in some instances shortage of coal, crippling the output. The closing down of the Mary Lee mines of the Alabama Company account of accidental flooding Sept. 3, has caused a heavy loss in the output of furnace coke by this company and the diversion of the output of Brookwood ovens for furnace use, this coke going largely to the foundry trade heretofore. The Fuel Administration has announced the following prices f.o.b. ovens for Alabama beehive coke, based on a net ton of 2000 pounds:

	Furnace	Foundry
Big Seam	7.00	8.00
Yolande, Cahaba, Black Creek, Jefferson	8.75	9.75
New Castle (Big Seam) Pratt, Brookwood, Nickel Plate	7.85	8.85
Empire Coal Co. (Black Creek)	....	10.50
Big Seam (Upper Bench)	8.50	9.50

Middle Western

GENERAL REVIEW

The present coal situation, in the Middle West, so far as market conditions are concerned, is peculiar. Coal that has been hard to get throughout the season is now being offered freely. In fact, practically the only coal which is sold without difficulty, and at full Government prices, is the higher grade products from the southern Illinois fields.

As a rule, except in some isolated localities, the domestic dealers have on hand all the bituminous coal their sheds and bins can hold. Generally speaking, this puts the retailer in a position to pick and choose, and naturally, he is now going to purchase only the best he can get.

The steam market is weak, especially for screenings, for two reasons—first because the average manufacturer has a substantial storage pile, and second, because numerous fires, caused by spontaneous combustion, have broken out in a great many storage piles. These fires have naturally caused the steam users to issue instructions, holding up the balance of their respective unfilled orders and, as a result, the market has been actually glutted with both mine run and screenings.

MILWAUKEE

Coke advanced 75c. per ton, despite the Fuel Administration's order making a cut of 30c. Byproduct companies hold that they are within their rights. Coal receipts continue heavy.

There have been no price changes in either hard or soft coal since last week's report. Retail dealers are taking no new orders for anthracite, as a rule, as they are barely allotted enough by the dock men to enable them to fill orders now on hand. Coke is also practically out of the retail market.

Coke is now selling at $11.50, an advance of 75c. The increase in price caused considerable comment, in view of the fact that the Federal Fuel Administration recently announced a cut of 30c. per ton in coke, except in the States of Alabama and Washington. Milwaukee coke producers claim, however, that they are really selling at 75c. less than the official schedule, and that they are entitled to $12.50 per ton. They hold that the base price of coke at Connellsville, Penn., is $6.20 per ton f.o.b. cars, after deducting the 30c. ordered by the Fuel Administration. Adding the freight rate from Connellsville, or $3.75, brings the total cost of coke landed in Milwaukee up to $9.95 per ton. These figures are increased by the addition of $2.25 per ton, the margin allowed coal men from vessel to cars or delivery wagons, making the total $12.20 per ton. These figures are held to be specious in a way, inasmuch as the freight rate on the soft coal used by the byproduct companies is 55c. per ton, and the $2.25 margin from vessel to cars and wagons is designed for yards handling coal solely as fuel. The cost of handling the coal from vessel to the ovens is in reality a byproduct expense. The leading byproduct company here claims to be 75,000 tons short in its coal supply, with no prospect that the shortage can be made up before winter sets in.

Coal receipts by lake thus far in September aggregate 61,228 tons of anthracite and 348,510 tons of bituminous, making 426,205 tons of the former and 2,494,922 tons of the latter thus far this season. As there are close to three months of navigation left, these figures are capable of being greatly increased.

ST. LOUIS

A continued quiet easy market with no demand for anything and steam sizes heavy. Country demand easing up. Domestic business almost at a standstill. Cars more plentiful and transportation better.

The market continues quiet, with nothing to indicate that there will be any change. The steam market is unusually inactive and screenings, mine-run and other steam sizes are heavy. The tonnage of this coal that formerly moved to Chicago is not going in that direction on account of storage piles being afire. Locally there is very little steam storage. The domestic demand is easy everywhere and the expected heavy demand from the country has not materialized.

In the Carterville field cars are a trifle more plentiful and transportation has shown improvement; the bulk of this coal still goes to the railroads and the rest is moving north on account of the zone restrictions, which will prohibit it moving into Minnesota after the 30th of this month. As a result little is going into the southern and St. Louis market. The past week was an unusually poor one in that field on account of the Illinois registration and primary, and the county fairs.

Similar conditions exist in the Duquoin field, with little of this coal moving in this way. There has been an usually heavy surplus of domestic coal and other sizes in the Mt. Olive field. Some companies have had a hard time keeping their mines going on account of no orders. A good tonnage of this is moving to the north, but not in sufficient quantity to relieve the local conditions.

In the Standard field the surplus continues, but to a greater extent, and many operators have had trouble keeping their plants running on account of having no place to ship their coal, and this is likely to continue for some time. The car supply in this field has shown considerable improvement the last week and transportation is better. The prospects are good for a rather quiet four or five weeks for the mines in this district unless something unusual occurs that will bring the coal into the northern market.

A little Arkansas moved in the past week. The St. Louis Fuel Committee held a hearing on byproduct coke and asked the producers to agree to a reduction of from $9.90 to $9. This will make the retail price on domestic coke $12.50, which would be the price of anthracite at this time. Gas house coke, prepared sizes, is $11.75, and lump $11.25.

The prevailing market is per net ton f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1	3.05@3.20	3.05@3.20	.....
No. 2	3.05@3.20	3.05@3.20	.....
No. 3	3.05@3.20	3.05@3.20	.....
Mine Run	2.35@2.50	2.35@2.50	2.20@2.30
Screenings	2.17@2.32	2.17@2.32	1.50@1.60

Special preparation on Carterville is 10 cents extra.
Williamson & Franklin Co. rate is $1.10.
Other fields 95 cents.

COAL AGE

Volume 14 — New York, October 3, 1918 — Number 14

Every scoop means a beltful of bullets — Every carful of coal means a shell

Straight Stuff

Written Expressly for Coal Age

By Berton Braley

Every scoop means a beltful of bullets,
  Every carful of coal means a shell
That'll shoot from our guns to abolish the Huns
  And set 'em to running pell-mell.
My drill barks a lot like machine guns,
  Re-echoing here in the room,
And the dynamite's sound when I set off a round
  Is the heavy artillery's boom!

So I think of myself as a soldier
  That's working down here in a mine,
And I toil heart and soul to be bringing up coal
  For the sake of my brothers in line.

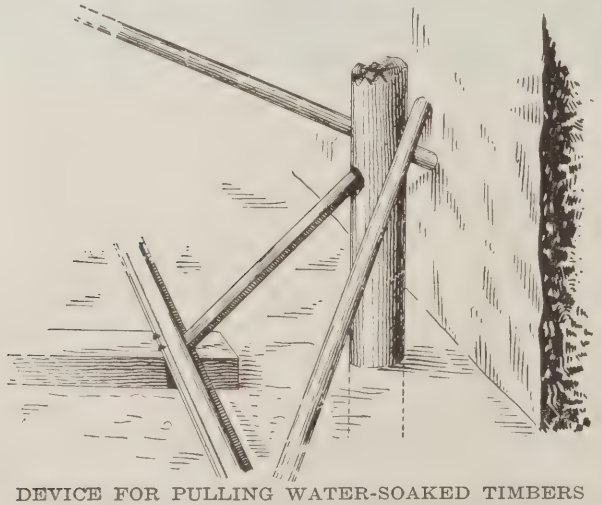
And whenever I'm feeling like loafing,
  I say to myself, "You big slob,
While the boys over there all are doing their share,
  I guess *you* can stick to *your* job!"

Yes, we're all either helping or hurting,
  According to which way we act,
When you slack or you quit you're not doing your bit
  And you can't get away from that fact.
Remember you're part of the army,
  And your record in tonnage will tell,
Every scoop means a beltful of bullets,
  Every carful of coal means a shell!

IDEAS AND SUGGESTIONS

Salvaging Buried Rails

BY ISAAC HYDE
Drumheller, Alta.



I was sent to pull out the turn rails from a pillar working which had caved, burying the rails (15 ft. long) to within 6 in. of their outer ends. I cleared the ends of the rails and fastened to each end a strong chain. I then used a Sylvester prop puller and with the aid of two men sprung the rails slightly from the spikes.

When the rails were somewhat loose, in order to facilitate getting the rails from under the cave I attached the chain to a loaded car. Starting the car as near the cave as possible, three men gave it such momentum that when the slack was taken up the pull was sufficient to draw the rail from under the cave. This saved much time over the slow process of using the Sylvester puller for the whole operation.

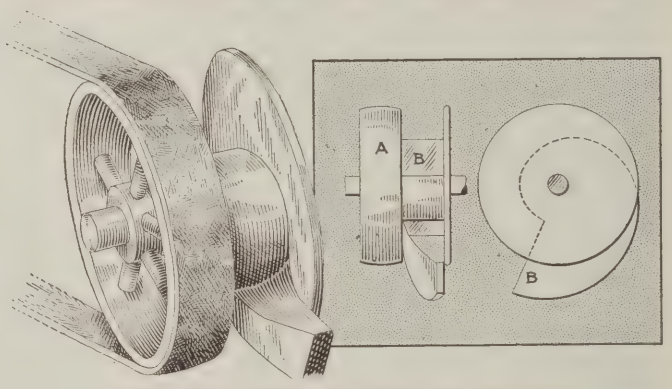
Pulling Heavy Timbers

BY WILLIAM LAWTON
Seattle, Wash.

While there is nothing new in the idea here described and illustrated, of a device used in removing heavy water-soaked timber sunk deep in the bottom, it may be of interest to some readers. Miners and others who have had experience in taking out old posts from the side of roadways in mines where the

DEVICE FOR PULLING WATER-SOAKED TIMBERS

ground is wet and sticky know how difficult the task is when the timber has been forced some distance into the bottom.



In the method here described a short brace or shore is placed against the timber that is to be removed and is prevented from slipping by the top being inserted in a notch cut in the timber for that purpose. The bottom of this brace should be secured against the rail or any other object that will give it a firm hold. Care must be taken that the brace or lifting device engages the timber at the proper angle to secure the maximum lift.

Suitable levers are now applied between the side or wall and the timber to be removed, and if the post is sunk deep the dirt in front of it should be loosened or removed to allow free movement when leverage is applied. This method is satisfactory in saving time and labor if no better means is at hand.

Replacing a Belt

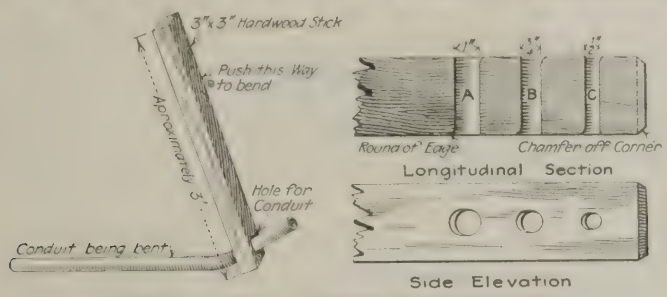
BY J. A. CAHEN
Brooklyn, N. Y.

The accompanying illustration shows a device for replacing a belt that has slipped off a pulley. *A* is the pulley and *B* the device for replacing the belt. This device has a curved projection extending the full width of the face and at one end comes even with the perimeter

SCHEME TO REPLACE BELT ON PULLEY

of the pulley *A*. It then tapers laterally toward the outside edge of the device.

As a result the belt will quickly pull upon the broad end and cause the device to rotate. The belt runs up the curved projection and lifts clear of the pulley *A*, but on account of the taper of the projection the belt finally has contact with the projection on the edge only, tips over to the other side, and as a result comes in contact with the face of the pulley. Because it is under tension and adjusts itself so as to be in line with the pulley at its other end, the belt now naturally and smoothly runs onto the face of the pulley.



"Hickey" for Bending Pipe or Conduit

A pipe or conduit bender of a simple type is shown in the accompanying illustration. This hand bender (which is known as a "hickey") is really a sort of lever. A tool of this design is not to be compared with a metal one for continuous operation but can, particularly for ½-in. or ¾-in. pipe, be made to do good duty, especially in an emergency.

The bender consists of a 3 x 3-in. hardwood stick (hickory is excellent) about 3 ft. or 3 ft. 6 in. long, having holes or slots bored in one end wherein the

tube to be bent may be engaged. In using this device a portion of the tube is held to the floor by the operator, who stands on it, and then by using the hickey as a lever the conduit which is engaged in its lower end is bent by main force into the required form.

If only ½-in. conduit is to be bent, only one hole and that only slightly larger than enough to accommodate

DETAILS OF A SIMPLE PIPE BENDER

the ½-in. pipe is necessary. If more than one size of tube is to be bent, holes of different diameters should be bored, as suggested. It is well to round off the opposite sides of the holes on opposite faces as shown, to prevent kinking of the pipe being bent.

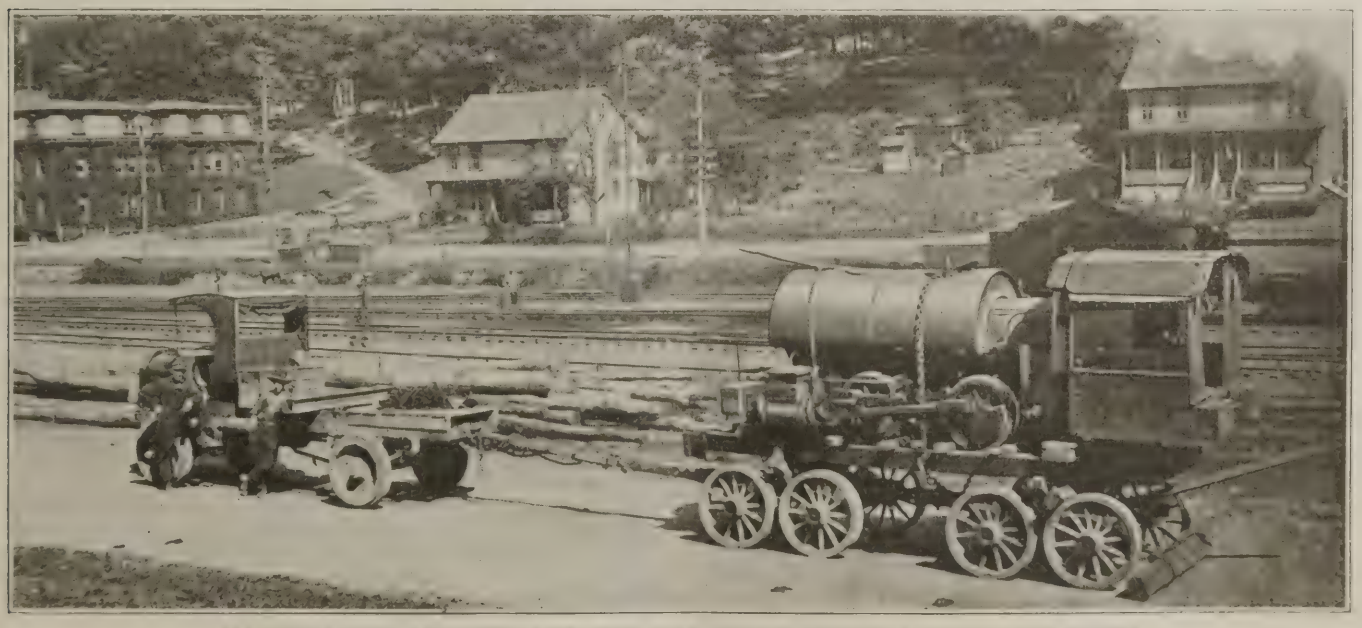
Heavy Towing with Motor Truck

The use of the motor truck has reached almost every industry. Some coal operators have been somewhat skeptical of its utility, but nevertheless many of these machines are being employed for heavy hauling in connection with coal mines.

The accompanying illustration shows a heavy four-wheel-drive motor truck, owned and operated by the Lehigh Coal and Navigation Co., towing an ordinary 12-ton locomotive upon a specially constructed wagon. The locomotive was transferred from one colliery to another about 5 miles away. It was necessary to climb and descend several fairly steep grades, yet the trip was accomplished without mishap.

In order to prevent the trailer or wagon with its load from running backward down hill should it break away on a grade, the method of automatic chocking shown in the illustration was employed. For this purpose a railroad tie was chained so as to drag crosswise of the road immediately behind the rear trailer wheels. So long as the trailer moved forward the tie interfered with nothing; but as soon as a retrograde movement started the tie was in position to immediately block or chock the wheels.

An Emergency Ventilator



By J. W. Jemison
Nanaimo, B. C.

The accompanying photograph shows some workmen about to enter the Chase River slope of the Canadian-Western Fuel Co., of Nanaimo, B. C., which is situated about 2 miles from the company's No. 1 shaft. This slope has been closed for over 30 years. It is believed, however, that much recoverable coal exists in these old workings, and the present owners are sufficiently enterprising to attempt its recovery. It will be noticed that

BLACKSMITH'S BELLOWS SUPPLIES AIR TO WORKINGS

an ordinary blacksmith's bellows is being pressed into service to supply air to the men down the slope. This bellows is connected to a 4-in. wood pipe, which extends down the slope to the face. This scheme, crude though it may seem, filled the requirements adequately. It will doubtless be replaced whenever it becomes necessary with a multiblade fan or other modern mine ventilator.

ILLUSTRATING ANOTHER USE FOR THE MOTOR TRUCK AROUND THE MINES

Concrete Coal Barges

By J. F. SPRINGER
New York City

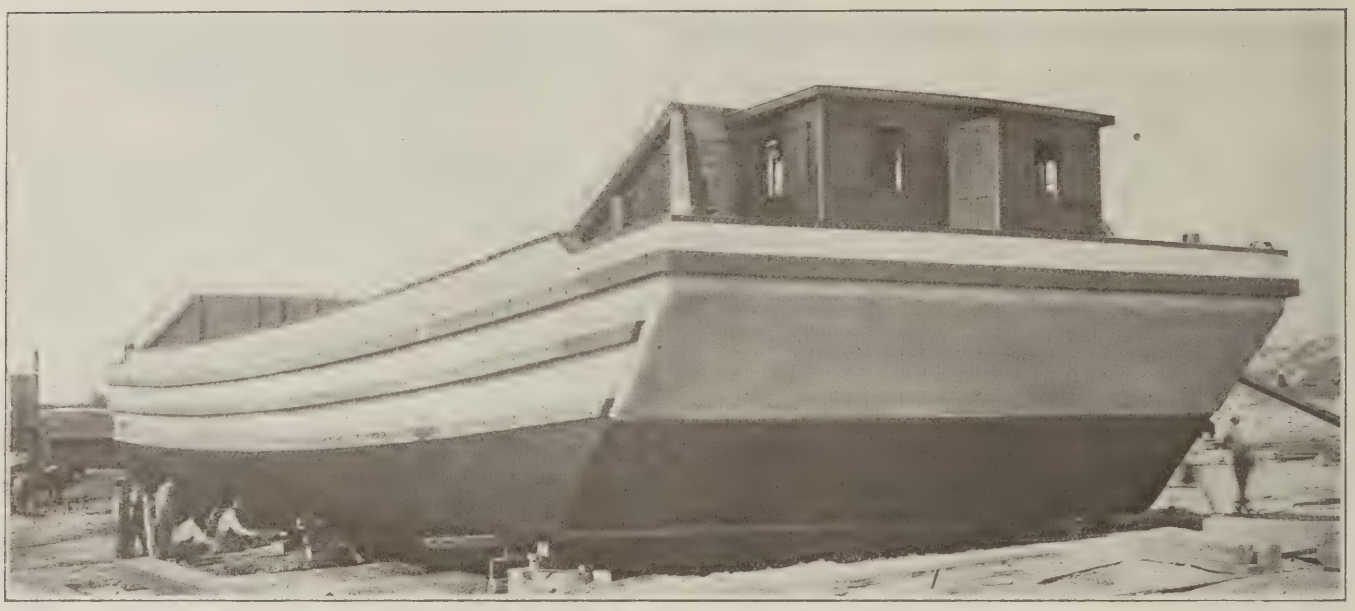


FIG. 1. A CONCRETE BARGE ON THE RIVER BANK READY FOR LAUNCHING

THE concrete boat has come. And, I rather think, it has come to stay. The great war has made it difficult and expensive to secure steel plate and timber. Thus it is no wonder that men have turned to reinforced concrete as a possible construction material, from which they might build both big and little vessels. The Norwegians, the French, the Italians, the Spanish, the English, the Canadians have all given expression to their belief in this material. So also have Americans.

As early as 1849 a reinforced-concrete boat was constructed at Miravel in France. It was nothing more than a modest rowboat. In 1917—nearly three-score-and-ten years later—this boat was said to be still in good condition. The builder was M. Lambot. Another French instance is of uncertain date, but occurred probably soon after the Spanish-American War of 1898 This was the construction of a barge 50 ft. long and 13 ft. wide. It was built for use in dredging builders' ballast, so that curved lines were unnecessary. The depth was made about 3 ft. 4 in. and a slope given fore and aft. Aside from these slopes, it appears to have been almost a simple box. "The initial cost was much less than for a steel or wooden vessel, and the expenditure for upkeep has been practically nil."

I understand that the Italians have been using reinforced concrete in coal barge or similar construction and that their experience goes back quite a number of years. An example of Italy's faith in reinforced concrete for boat construction is a coal barge built in 1906. Its capacity is 150 tons. The length is 52 ft. 6 in., the width 24 ft. 3 in., and the depth 9 ft. 10 in. In 1917, this barge was said to have given good satisfaction and that it had been constantly in service.

The Norwegians have a 200-ton motor-driven reinforced-concrete vessel in coastwise traffic. Her power unit is an 80-hp. oil engine, sufficient to drive her at 7½ knots per hour. This is the "Namsenfjord." The concern which built this boat has constructed many reinforced-concrete vessels, one at least being a lightship for the Norwegian Government. The "Namsenfjord" is 84 ft. long, 20 ft. wide and 11 ft. 6 in. deep. Her builders have contracted for an ore-carrying vessel to have a capacity of 4000 tons.

The French are going in heavily for the construction of the smaller-sized vessels of reinforced concrete. These are for coastwise and inland service. But the chief example of solid confidence in reinforced concrete for vessel construction is to be found at home. The "Faith," launched this year at San Francisco, is a 5000-ton vessel. She has already had her trial trip in San Francisco Bay over a measured course and developed a speed of 10⅓ knots per hour. The trial trip was about 40 miles in length, and made it clear that the "Faith" was going to be a manageable ship and that but little vibration was to be expected. The United States Government, since her launching and try-out, has contracted for forty 7500-ton concrete vessels.

It looks as though reinforced concrete were about to secure enormous recognition as a suitable shipbuilding material. And yet, objections have been raised to it. This is, of course, nothing more than history repeating itself. It would seem as if no considerable deviation from a beaten track could be made without an accompaniment of dead marches and dirges. In the February issue of *International Marine Engineering*, Prof. B. A. Everett, who is understood to hold the chair of Marine Engineering in the Post-Graduate Department of the U. S. Naval Academy, expresses himself doubtfully as to vessels of more than 250 ft. in length. He says:

> To sum up briefly, we are justified in expecting success for reinforced-concrete construction for barges, still-water craft and perhaps small ocean-going craft of simple form, but are entirely unjustified at the present time in expecting large ocean-going craft to be successful, and should not be led astray by undue optimism.

Professor Everett seems to fear that water, particularly salt water, will reach the reinforcement and effect corrosion and that this expanding will rupture the enveloping concrete. This is really a vital matter and not to be dealt with in a trivial manner—it is not easy to see, however, why it should not be a fatal objection to "small ocean-going craft," the "simple form" affording no protection against the penetration of sea water.

The question itself is a real one, especially in connection with coal-carrying craft used along the coast and in tidewater harbors. Concrete boats and barges for carrying coal on such inland waterways as the Great Lakes, the New York Barge Canal, the Ohio-Mississippi route, the Warrior-Tombigbee-Alabama route, etc., will doubtless come into use. We are also to expect them in service along the Atlantic coast between such southern harbors as Hampton Roads and Baltimore and such northern destinations as Providence and Boston, also on the Pacific coast between San Francisco and points to the north. Cuba and the Panama Canal may represent other points to which coal may be sent by means of the concrete vessel.

If salt water is going to penetrate to and corrode the reinforcement and thus bring about physical rupture, this should be known. But I am afraid, however, that an unfortunate error has been made in this connection. Profound differences can be made in reinforced concrete by variations in the character of the constituent materials and by variations in the proportions used. Naturally, some concretes are bad and subject to almost anything. That there are many examples of disintegrated and ruptured concrete, the disintegration and rupture being due directly or indirectly to salt water, might perhaps be acquiesced in pretty generally by concrete experts.

The unreliability of external waterproofing is admitted. This has no reference, however, to integral waterproofing—that is, to waterproofing which is incorporated into the concrete when it is mixed and in this way made an integral part of its mass.

But let us look at the matter broadly. There are thousands and thousands of linear feet of reinforced-concrete piling, struts and the like standing in salt water. Some of this has been so situated for years.

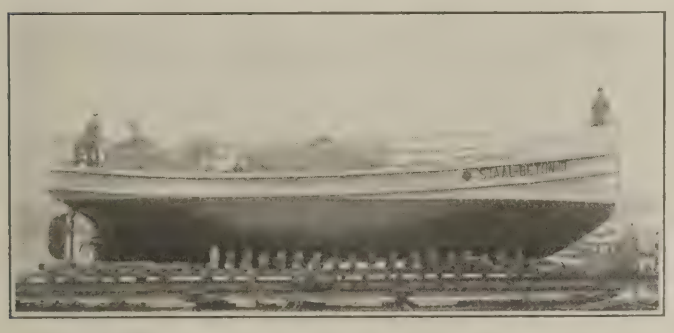

FIG. 2. CONCRETE MOTOR BOAT ON THE WAYS

Hard-headed people have been responsible for a good deal of this construction.

Many such piles were put down not so long ago in the harbor of Halifax. A similar statement may be made in connection with the harbor of Havana. These piles were put in place with the expectation of perpetual exposure to the action of sea water. If salt water is going to penetrate to the reinforcement and the reinforcement is going to corrode, then such construction should soon manifest vertical cracks and this condition should soon be followed by disintegration and collapse. A considerable proportion of the tidewater harbors all over the world contain reinforced-concrete construction of some type or other, and some of it has been in place a good while.

In Europe concrete has been successfully employed for half a century in the construction of structures

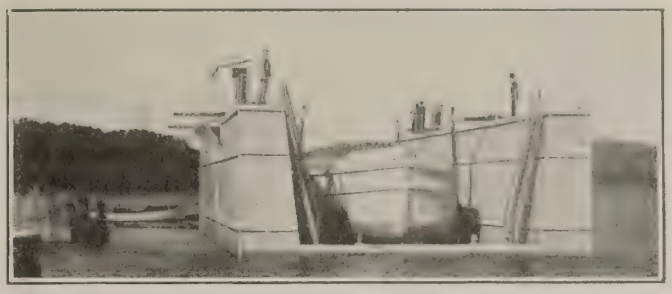

FIG. 3. A CONCRETE VESSEL IN DRY DOCK

exposed to the action of sea water. English engineers for a score of years have been building reinforced-concrete docks. At Liverpool, there has been concrete used in connection with dock construction since 1872. William Cleaver, writing of the concrete docks of the Port Talbot Dock Co., has been quoted as saying: "While reinforced concrete requires extreme care, both in the choice of material and in the supervision of the workmanship, the results justify the extensive adoption of the material for dock work."

In Holland, V. de Blocq van Kuffeler has, it seems, been responsible for reinforced-concrete construction destined for exposure to salt-water action. He is quoted as explaining in the following manner how to get satisfactory results: "A suitable mixture, very carefully manufactured, the use of a good brand of cement with trass, and setting in a moist atmosphere, are the most efficient means of insuring the preservation of reinforced concrete in sea water."

Here the integral waterproofing is trass. This is a variety of volcanic tufa found on the banks of the Rhine as it nears the sea.

C. S. Meik, a British concrete engineer, is cited by Mr. Taft as stating that the deterioration of the reinforcement in reinforced concrete by the action of salt water is negligible. In fact, Mr. Meik refers to an instance at Southampton, England. "The exposed steelwork on a pile end that had been in the sea for eight years was much corroded," but the bars in the body of the concrete were found, when the pile was opened up, to be entirely free from rust. They were pronounced to be as fresh as the day they were put in. Mr. Taft continues: "In connection with the building of some of the earlier concrete dock structures at Southampton, it appears that parts or the whole of piles not used were allowed to remain on the beach or shore, exposed to sea water, for some seven years. At the end of this period, the exposed steel had been badly rusted and deteriorated, whereas the part which was imbedded in concrete was found to be in fine condition, practically as good as the day it was placed in the concrete."

Enough instances of the permanence of waterproofed reinforced concrete can be found to warrant the expectation that it is possible to construct a reinforced-concrete

hull in which the reinforcement will be adequately protected from the action of sea water. It is to be borne in mind, however, that just any concrete will not do. The salient consideration in such construction might be enumerated as follows: (1) It must be rich in some high-grade Portland cement or its equivalent; (2) the coarse aggregate must be practically impervious; (3) it must be free from particles of clay, loam and the like; (4) the proportions of the several ingredients must be such as to insure their utmost consolidation; (5) the highest class of integral waterproofing should be incorporated into the mixture; (6) the mixing and placing should be absolutely controlled by experts.

I may illustrate the point as to the richness of the concrete by citing the material used in the hull of the "Faith." This concrete was specified to conform to the formula, 1 : 1½ : 2. Here we have a total of only 3½ parts of aggregate to 1 part of cement. This means a concrete that is not merely rich—it is one that is extraordinarily rich.

Item 4, as mentioned above, may also be illustrated by this specification. It is essential to an impervious concrete that all voids be filled. The only thing to fill the voids in the sand is the cement (or cement and water). Naturally, then, the ratio must be such that there will be no interstices. It is not enough to ascertain the volume of the sand voids and then provide just that much neat cement. For this to bring about success, the mixing would have to be perfect. There must be a generous excess to make good the imperfections in mixing. In the present case, the ratio was taken as 1 : 1½. This means that the sand was given cement to the extent of 67 per cent. of its own volume. Probably, the actual voids were not in excess of 40 to 50 per cent. If so, cement enough, and at least one-third over, was made available.

Similarly, with the voids in the rock aggregate. The only thing available to fill them is the cement mortar. Assuming—what is not quite the exact truth—that the relative amount of cement mortar is given by adding the first two figures in the formula, we have the ratio 2½ : 2 as expressive of the relation between cement mortar and rock aggregate. Probably, here again, the voids in the rock were not in excess of 50 per cent. of its own gross bulk. The specification required, nevertheless, that mortar be supplied in amount equal to 2.5 times the probable volume of voids.

As to item 2, it is fairly evident, upon a little consideration, that absolutely solid concrete cannot be made with course aggregate that lacks solidity. Item 3 requires the absence of all foreign material itself incapable of consolidation into a mass of high cohesiveness.

The integral waterproofing required by item 5 may be an artificial compound or a natural one. It must, however, fill all minute voids, and effect an impervious consolidation. Trass has already been mentioned for this purpose.

FIG. 4. MOTOR-DRIVEN REINFORCED CONCRETE LIGHTER

Item 6 has its place, not merely to round out the list, but because of its vital relation to success. All the requisite materials may be employed and yet success be perfected, because of some deviation from the best technique.

Let us now leave imperviousness and consider the question of shocks. Some may be apprehensive as to what will take place when, for example, a reinforced-concrete vessel bumps into or rams a pier. If the pier is not a good one, we may expect it to be damaged. At the worst, the injury to the vessel will probably be rather sharply localized. Naturally, there is but little information available from actual experience with concrete vessels. There is, however, a pretty good equivalent in the shape of experience with other concrete structures that have been subjected to shocks.

Shocks are of two kinds: The cushioned impact of a heavy bulk; and the rapid, projectile-like blow of a swiftly moving object.

As to cushioned impacts, a good example may be found

in the regular practice of driving reinforced-concrete piles with a pile driver. Practically the only difference between driving reinforced-concrete piles and ordinary wooden ones is that with the former the blow may perhaps be cushioned more carefully by a more elaborate system of blocks between pile and ram. The driving of reinforced-concrete piles by means of a cushioned blow is no unusual thing. It is the regulation practice. Thousands and thousands of such piles have been driven in this way. This consideration, by itself, is fairly convincing.

That reinforced concrete readjusts itself when subjected to slow-acting stresses would seem to be indicated by the case of a British monolithic reinforced-concrete building, which was in 1909 erected on 20 piers in a location subject to subsidence. In the course of six years actual subsidence took place. An inspection was made, revealing that 12 out of the 20 piles had lost contact and that there were only eight actually supporting the building.

This means that an extraordinary readjustment of stresses had taken place. Nevertheless, the investigation of the whole structure "failed to reveal any trace of weakness or strain," although the investigators paid "special attention to main beams, secondary beams and ceilings."

Another instance may be cited. A reinforced-concrete boat 64 ft. long between perpendiculars and having a weight of 58 tons was, when the deck was 50 days old and the sides 30, put under the stress of being supported at the two ends and of having the unsupported intermediate section 40 ft. in length weighted with 16 tons of evenly distributed load. The maximum shear was estimated at 26½ tons at the inner edges of the supports and the maximum bending moment at the center of the span at 419 foot-tons. A deflection of $\frac{1}{16}$ in. was observed. "There were no signs of surface cracking, flows or weakness of any kind."

A slow-acting blow was, in another instance, delivered to a reinforced-concrete pier by a vessel (of other material) rated at 8000 tons. Some damage was done, but it was confined to a few piles and some 20 sq.ft. of the decking of the pier. So much for the effects of slowly acting and cushioned blows.

The sudden blow is not an experience unknown to reinforced-concrete construction. A big explosion occurred at a British port, resulting among other things in the hurling into the air of a large steel girder. This came down endwise upon a reinforced-concrete wharf. It pierced the decking, but the damage was all localized in a section about 1 x 2 ft. in area. It is said that the adjoining beams suffered no damage at all.

No claim is made for reinforced concrete that it will resist any and all quick blows. Steel does not do this—as witness the piercing of heavy armor plate by projectiles—neither does wood. A strong, swift blow, sufficiently concentrated, must necessarily perforate any material, but reinforced concrete in such a case behaves admirably and receives only localized damage.

Another case illustrating this is as follows: On the Western Front opposite the British lines stood at one time a concrete water tank on trestlework at an elevation of some 50 ft. The Germans in retreating from the position dynamited the trestle legs, thus bringing the tank to the ground, "but according to written statements the shells which had struck the tank merely made circular holes through the sides and bottom."

From the foregoing it would appear that we may expect good behavior from a concrete boat or ship in a great range of accidents which befall both fresh and salt water craft.

A still further objection appears to have been brought against concrete boats. It is claimed that they are heavier than steel craft of equal cargo capacity. The validity of this objection will be at once admitted—at least up to vessels of considerable size. But this excess weight is not a serious objection, and has certain compensations. Perhaps the excess is sufficient to keep concrete craft out of the class of swift passenger vessels. The reason that a concrete boat is heavier than a steel vessel of equal tonnage centers largely upon the fact that it requires a relatively thick-walled hull to take care of tensional stresses. The specific gravity of reinforced concrete is moderate, being not more than, say, 2.75; while steel is heavy, having a specific gravity of, say, 7.85. Steel is, in fact, bulk for bulk, nearly three times as heavy as reinforced concrete. Consequently, the few inches of thickness required in the

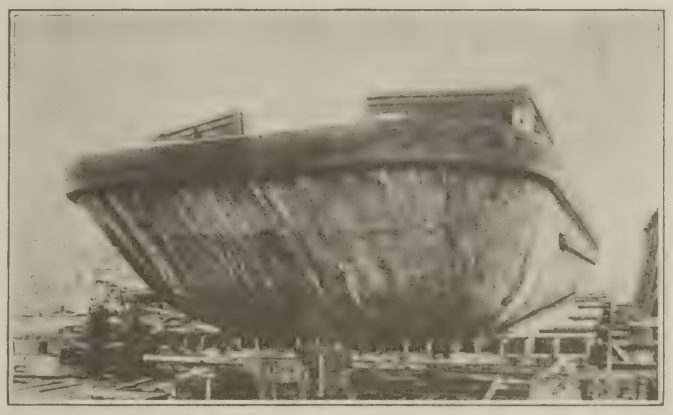

FIG. 5. A LARGE CONCRETE COAL BARGE

hull of a concrete boat do not mean such an extraordinary weight, after all.

There have been elaborate calculations showing the comparative weights of concrete and of steel vessels. These figures go up to the 6000-ton size, which is about the largest sized vessel designed for the coastwise coal-carrying business. First, we have the figures for unequipped vessels, then for vessels equipped. The latter are the more important figures, since the vessels must of course have their equipment on board. These data as given by T. J. Guerrite, are substantially as follows:

UNEQUIPPED VESSELS—EXCESS WEIGHTS OF CONCRETE CRAFT

	Deadweight Carrying Capacities in Tons			
	1000	2000	4000	6000
Excess percentages	39	25.8	16.5	11.8

EQUIPPED VESSELS—EXCESS WEIGHTS OF CONCRETE CRAFT

	Deadweight Carrying Capacities in Tons			
	1000	2000	4000	6000
Excess percentages	104	84	58	43

It is clear in both cases that while the relative excess is considerable for small vessels, this decreases rapidly as the size increases. The accompanying curves apply to decked cargo-carrying vessels in general and not to coal vessels primarily. They, however, give us the trend of the facts.

Fig. 7 exhibits the case, roughly, of concrete barges that are to be towed, while Fig. 6 shows the situation broadly governing self-propelled concrete barges.

While the former curve does not descend with the same rapidity as the latter, it is to be noted that it begins at a much lower point.

The standard size of coal boats towed from Pittsburgh to New Orleans is about 1000 tons. The curve (Fig. 7) shows that the concrete barge would be about 40 per cent. heavier than a corresponding steel barge. But, so far as I am aware, there are but few steel boats in this business, or none at all. At least the vast majority of the barges employed are of wood. This means that they are probably heavier than if they were of steel. In short, 40 per cent. is probably too large a figure for the excess weight of the reinforced-concrete towed barge over the wooden towed barge now in use.

This question of comparative weight is probably not particularly important in connection with the Ohio-Mississippi traffic, for the reason that the towboats

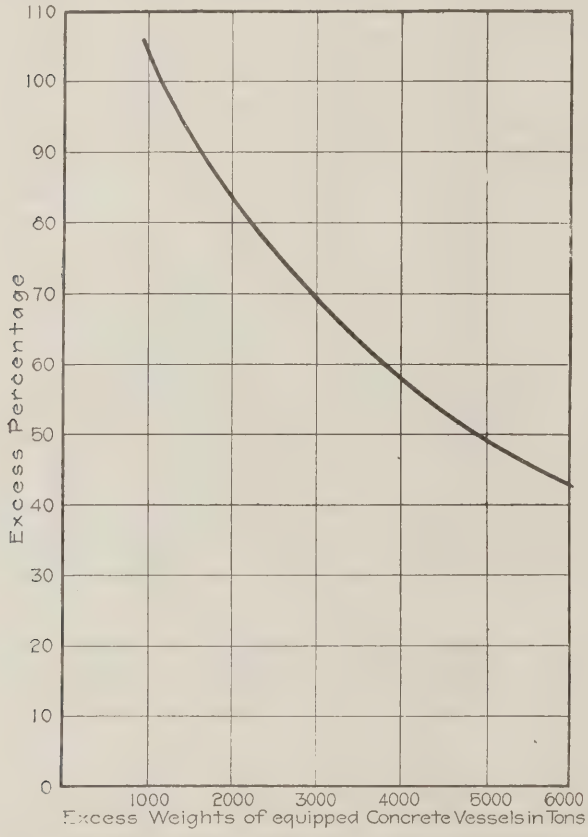

FIG. 6. COMPARATIVE WEIGHTS OF EQUIPPED VESSELS

consume relatively small amounts of fuel in their power plants as compared with the tonnage transported. Thus, the "Sprague" is one of the largest of the towboats running below Louisville (that is, from below the Falls of the Ohio), and yet its horsepower is rated at only 2175. The tonnage towed by this boat varies; but she has handled up to 56,000 tons loaded on 56 boats. The "Kaiserin Auguste Victoria" had, I understand, a cargo capacity of only about half this amount and yet her horsepower was 17,200.

Evidently, then, the handling of tonnage is an enormously different matter when done on inland rivers from what it is when done on the high seas. Thus even if reinforced-concrete towboats are 40 per cent. heavier than wooden ones, this difference will not play any big part in the operating costs.

As to coastwise coal traffic, we have both types of boats, the towed and the self-propelled, to consider. Offhand, one would say, after looking at the curve of Fig. 6, that it would seem that it would be mainly the bigger boats that would be profitable. Towed boats, it would appear, might well be larger than 1000 tons and thus secure the advantage of lesser weight.

As to the comparative costs of reinforced-concrete vessels and steel ones, it has been estimated abroad that on a pre-war basis the concrete hull would cost about 30 per cent. less than a steel hull of the same deadweight carrying capacity. The equipment for power-driven concrete vessels would be, however, about 5 per cent. greater.

One condition that we have now to reckon with is the possibility that it may soon become not merely difficult but impossible to secure steel plate for the purposes of barge construction. After the war, we may expect a continuing difficulty and also a stiff price because of the demand for steel that will be needed for reconstruction in Europe. Likewise, wood will probably continue expensive and more or less difficult to procure.

A further economic argument for concrete relates to the maintenance expense. This is an important point.

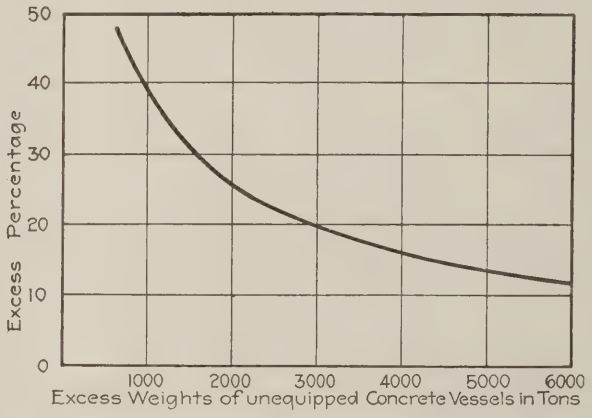

FIG. 7. COMPARATIVE WEIGHTS OF STEEL AND CONCRETE VESSELS

We have, perhaps, but little actual experience with concrete boats to fall back upon, although we have some, but we do have a big experience with other forms of reinforced-concrete construction. The 50-ft. barge previously mentioned is understood to have necessitated no expense whatever for its maintenance. We have knowledge of the ease, rapidity and inexpensiveness of ordinary concrete repairs, and would naturally expect the same to apply to boat repairs as well. Probably, nearly all repairs will be susceptible of execution as the boat floats in the water. This includes repairs to submerged portions of the hull.

For quick and efficient work after a mine disaster has occurred, a map of the mine is indispensable. Blueprint copies of the mine map should be furnished the captains of the rescue crews, the shift bosses and the official in charge of the recovery work. If a supply of maps is not available one map should be posted near the mine entrance for the convenience of all concerned. A line sketch of a map can be quickly made by an engineer and will be of much advantage to the rescue and recovery crews. Experience has proved that at least a dozen blueprints of the mine map should be kept at all times in close proximity to the mine.—*Rescue and Recovery Operations in Mines.*

Rocky Mountain Coal Men Meet

THE summer meeting of the Rocky Mountain Coal Mining Institute was a joint convention with the American Institute of Mining Engineers and was held in Colorado Springs, Colo., Sept. 3 to 6 inclusive. About sixty coal-mining men were there, while more than 300 metal miners were in attendance. A number of side trips were indulged in by those present. One day was spent at Pueblo, Colo., investigating the new byproduct plant of the Colorado Fuel and Iron Co. One of the most modern coke plants in America has been erected by the Colorado Fuel and Iron Co. A. C. Watts, chief engineer of the Utah Fuel Co., who has been serving as president of the Rocky Mountain Coal Mining Institute, was again tendered the office, but requested that the institute relieve him of the responsibilities. Thereupon John McNeil, one of the pioneer coal men of Colorado, was elected president. F. W. Whiteside was reëlected secretary-treasurer. All of the meetings conformed to the spirit of the times and bore a war flavor. The discussions as well as the papers that were read dealt primarily with safety and efficiency in mining. Practically all of the "regulars" were on hand, except a few of the familiar faces from Wyoming, and although Colorado is now in the "dry" column of states the crowd managed to shed its war worries and renew the ties of goodfellowship after a year of suspended activity due to the war. Following are some of the papers read.

Wartime Economies

By George B. Pryde
Cheyenne, Wyo.

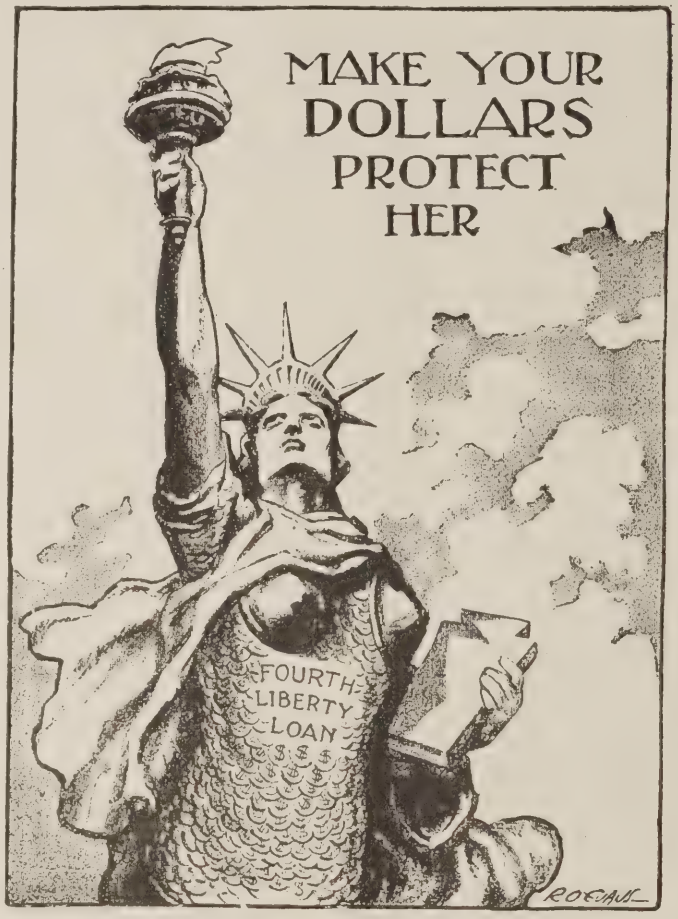
IT WAS suggested to me when I was asked to write this paper that on account of the war activities affecting every phase of our industrial life the subject should be along war lines. I have therefore chosen war economies as a subject particularly applicable. There are many kinds of war economy that might be reviewed, but I shall consider only those things that apply to the mining of coal, as this more directly concerns us. At a time such as this, when priority orders are necessary to obtain supplies that are absolutely essential to the production of coal, it seems it is obligatory for us to practice the most rigid supervision in the handling of material of all kinds so that none may be wasted; indeed, this is a national necessity as well as a duty that devolves upon us.

Allow me to call attention to one phase of mining in which there is considerable waste; that of lubrication. This is a subject, I am afraid, that is often given but little attention. When we consider the large amount of machinery that is necessary to operate a modern coal mine, and that all the bearings must be properly lubricated to insure smooth working and normal life, as well as to prevent serious breakdowns, you will readily understand how necessary it is to provide for and insure proper lubrication.

Much good can be done in this direction by the large oil companies, who have trained men in the field and are always glad to be of assistance. The proper kind of lubricants for certain kinds of machinery should be given careful and serious consideration. It may not always be a question of providing the most expensive lubricant and relying upon this to be sufficient. Great care must be exercised in studying the conditions under which the machinery must operate, and then applying a suitable lubricant thereto.

The condition of mine machinery in regard to lubrication is so familiar that it would seem to be unnecessary for me to call attention to it. In fact, this might be classed as one of the subjects that become stale by repetition. Too often the person who is charged with the care and operation of machinery seems to think that the machinery itself will operate more smoothly if covered with oil and grease, forgetting that the proper and only places to lubricate are the bearings and rubbing surfaces. I believe I am safe in stating that if proper attention were given to this subject at least 15 per cent. of our bills for oil and oil products could be saved. At a time when these products are in strong demand for the prosecution of the war—for the ultimate triumph of humanity—it would seem to me that this is a subject that is of national importance and one that demands of us the most serious and earnest consideration looking toward eliminating waste and making for greater economy.

The subject of blasting and blasting material is one which also plays an important part in our mining operations. On account of the large amount of explosives that are being used today in the world war, and the increasing cost of our mine explosives and supplies, frequent inspection of the methods of storing, distributing and using should be made to prevent either waste in handling or the overcharging of holes. Many of our best blasters have gone into the service of the United States and into other occupations, and the new employees at these jobs are more or less unskilled. Thus the necessity for this inspection is immediately apparent.



The substitution of duplex iron wire for copper wire in blasting will be found to produce a considerable saving. The wire is used in connection with No. 6 dry cell batteries, and when electric cap lamps are used in the mines the lamp batteries are employed for blasting purposes. The foregoing may seem a small item, but when the high cost of copper is considered, the annual saving, especially in large operations, will be considerable.

In pillar work, where motors are used for haulage, it has been found a good system to use galvanized iron wire in the vicinity of the workings. In this kind of operation sudden caving frequently occurs burying and losing the trolley wire. Since galvanized iron is cheaper than the copper wire, the saving is evident.

For distances up to 2500 ft., on motor roads where 16-lb. rails are employed, it has been found economical to use old wire rope for a return. The rope used is generally from $\frac{3}{8}$ to $\frac{7}{8}$ in. in diameter, and is laid alongside of the rail together with a No. 6 bare copper wire. The rope and copper wire are tied together every

60 ft. and cross bonds to the rail are put in every 150 ft. This provides a good return, saves the labor of drilling and bonding the track, which is quite an item in these times of labor stringency, when it is necessary to conserve every man possible for the actual production of coal.

In erecting a high-tension power line recently, it was found that good results were obtained by putting the cross arms and insulators on the poles before raising them. To do the raising required considerably more men; but as unskilled laborers were more plentiful than skilled linemen, and time was an important consideration, the experiment was tried with good results. This may not be in accordance with common practice, but on account of the prevailing labor conditions the method worked out satisfactorily, and the line was completed in fairly good time; certainly in a much shorter time than if it had been found necessary to wait for a sufficient number of trained linemen to complete the work. While the figures are not yet available as to the cost, I am sure that it will compare favorably with erecting the poles and then putting on the cross arms and insulators, even though more unskilled laborers were required. In connection with the stubbing of pole lines, it has been found that the reinforcing with concrete at the bottom of the poles has worked out satisfactorily. This system is nothing new, as it has been followed for several years, but as between stubbing and concreting I consider the latter preferable as a war economy, because the work can be done with common labor, whereas the stubbing requires that more or less of the work be performed by skilled linemen. The concreting is much more durable and has the merit of saving skilled labor, and anything that does this may be classed as a war economy.

The use of steel ties has been experimented with to some extent for several years, and these experiments have reached the stage where the use of such ties is recommended, especially in low seams. They are particularly adapted for this kind of work, for they provide a good rigid track and give greater headroom than the ordinary wooden tie, thus cutting down the taking up of bottom to provide sufficient height for haulage purposes. They are easily and quickly laid, and while they will cost about twice as much as a wooden tie, their longer life and adaptability as a labor saver recommend their more general use in mining low seams.

The war has made a heavy demand upon our timber resources, not only in this country, but in all of the countries at war. In France many of the finest forests have been destroyed by fire and shell, and it will take years to replace that which has been destroyed and grow timber to take its place. On account of these conditions in Europe there will continue to be a heavy demand upon our timber resources for many years to come, both for use in our manufacturing industries and for shipment abroad. The conservation of mine timber is something that should demand our serious consideration. Timber is one of the most essential materials which we use in mining work, and before many years substitutes of steel and concrete or both will be required, and the cost of these will be much greater than that of timber. There are two ways by which timber can be conserved; namely, treating the timber that is to be used in permanent work, such as for timbering haulageways, main air courses and the ties for the main haulageways, and the recovery of timber in rooms and pillars. When it is considered that an 8-ft. prop at the working face costs about 50c., it will be understood that it does not require much effort for a man to recover enough timber to make his work attractive from an economical standpoint. The objection may be made that this is dangerous work, likely to increase the casualties; but with the different kinds of mechanical prop pullers on the market today this work can be made fairly safe; in fact, as safe as any other operation, if men of good sound judgment are used to do this work. In the mines of Europe for a great many years the subject of recovering mine timber has been given close attention, on account of the high cost of this material, and these conditions are rapidly approaching in this country. It is safe to assert, I am sure, that not more than 5 per cent. of the mine timber put into American mines is ever recovered; but more and more this question will demand our serious and careful consideration, from the standpoint of conservation and national economy.

Previous to the war, all mine supplies could be purchased at a very reasonable price; in fact a good deal of machinery was scrapped because it was nearly as cheap to buy new machinery or new parts as to repair the old. Now this condition is changed, and with the high prevailing prices of all machinery and supplies, and the slow delivery, I am sure it would be a good idea to give the scrap piles at the mines close

scrutiny. No doubt we shall find much material that can be used over again, thus saving new supplies. It may not be just what is wanted, but with minor changes it may be possible to substitute and adapt it to requirements. Care should be exercised in scrapping material these days, and old material should be used and worked over as much as possible because labor is a scarce commodity today, and anything that will save a man's labor and relieve him for some necessary work is worth our greatest efforts. We will be doing our bit toward winning the war, just as much in this way as in any other.

Of course, I do not wish to be misunderstood, or to be taken to mean that in advocating the use of scrap that new material should not be ordered, as a certain amount of new material is necessary; but I certainly would watch carefully indiscriminate scrapping.

On the other hand, material that has been definitely scrapped should be removed as rapidly as possible, not only from the standpoint of cleaning up the plant, but more particularly because the nation needs it in the prosecution of its war work. It can be rapidly converted into new material with a minimum of labor, and so we owe it to ourselves, as well as to the nation, to see that this material is used as a national asset.

Much guessing is being done today as to what will happen after the war. More particularly the probable effect of the after-war conditions on our labor supply is being closely studied and forecasts made. One guess is just as good as another these days, because events from a social and economic standpoint are changing so swiftly as to make our views and beliefs of yesterday past history tomorrow.

Some people tell us that on account of the heavy taxes that will be necessary for the restoration of the countries at war the laboring men of these countries will flock to the United States to escape taxation; others tell us that there will be so many opportunities for business of all kinds after the war that many of our foreign-born citizens will return to their own countries in preference to continuing their residence here. Regardless of these different views, I believe it is reasonable to suppose that on account of the rapid depletion of their man power by the ravages of war, stringent laws will be passed by the present belligerents against emigration; in fact, I believe that inducements will be made for those of other nationalities to settle in these countries.

On account of the vast work of restoring those nations which have been at war, much of the material for this work will have to be furnished by the United States. It looks, therefore, as if we will have a labor shortage for years to come, particularly in coal mining. Many of the mines of Great Britain have been shut down during the period of the great war, and it will take years to put them on a producing basis. Some of the most productive mines in France and Belgium are in the hands of the Germans, and when these are returned, they will be so badly wrecked that it will require years of patient effort to put them in operation again, while some it may not be wise to reopen at all.

All this would indicate that the United States must supply the coal deficit of these nations for years. This will mean that we will have to improve our methods of production, and the only way to do this is by a greater use of machinery in the mines—increasing the number of haulage motors, the cutting of a large percentage of coal with mining machines, the greater use of electric drills and loading the coal mechanically. Probably the item that appeals to us most is the last one mentioned, for while many loading machines have been tried out in the last few years, few have been successful. In the high coal beds, where the roof is good, the loading of coal by electrically operated shovels does not present many difficulties. What is wanted today is a loader that will operate successfully in beds from 6 to 12 ft. high.

I am in hopes that after the war, when so many men will return to civil life with good mechanical training, someone will work out a shovel with few moving parts—one that can be operated by one man. A shovel of this kind that could load 50 tons per day, and could be put on the market at a low cost, would be much better than one that could load 150 tons per day where the cost and maintenance are high and where several men are required to operate it. For coal under 6 ft., conveyors will come into more general use through a system of longwall or modified longwall operation.

Increased Production in Wartime

By R. M. Magraw
Hiawatha, Utah

In This paper I will not attempt to show the relationship of coal to war, but will endeavor to indicate, by a few suggestions, methods which appeal to me as being worthy of consideration. Some of these, if followed, might lead to increased production.

Everyone should be thoroughly familiar with the importance of coal in the present crisis. The daily papers, technical publications and other periodicals have from time to time contained articles dealing with some phase of the situation. And among other commodities which it has been stated would win the war, coal, I believe, occupies a commanding, if not an impregnable, position.

This has been called a "war of science," and certainly more than ever before have scientific appliances and methods been called upon as an aid to man power by all of the belligerents. Brute strength without scientific backing would be impotent. Had it not been for the perfection and precision of the French field pieces at the first battle of the Marne, we would probably now be fighting the Huns on our own territory.

The coal industry was formerly held in low esteem by the public. Persons employed in it were looked upon with commiseration and pity by the average citizen, whose knowledge of coal mining and its importance to the industrial life of the nation was slight. At the present time, however, it is doubtful if there is a man in the United States who questions the importance of the coal mines. There seems to be also a much greater respect shown for the industry, and for its employees. But, lest we merit a return of the public to the first mentioned attitude toward us, we should utilize every scientific method known, not only to increase the output of our mines but to so prepare our product that the greatest number of heat units can be transported and stored in the smallest possible space.

Proof has been adduced that the coal shortage was and is due more to lack of adequate transportation facilities than to inability on the part of the coal mines to rise to a situation, which is acknowledged to be serious in the extreme. Notwithstanding the patriotic efforts of a majority of the mine operators and their loyal employees, the situation grows more acute and we are falling behind the schedule set by the Fuel Administrator as being necessary to maintain if we are to avoid a serious shortage in the near future. Placing the blame on the transportation lines, however, does not absolve the coal mines from all responsibility, neither does it utterly condemn the railroads, as the fault is not entirely theirs. They have been hampered and heckled by Federal, state and local legislation, and so-called regulation for years. And while it is true that the "public-be-damned" policy, inaugurated by some of the earlier railroad magnates and followed by others at an even later date, was responsible for the spirit of antagonism and lack of sympathy to all transportation companies, shown by both press and public, it is also true that the attempted regulation was carried to an extreme, with the result that all incentive on the part of the railroads to expand and prepare for the future was removed. Furthermore, the herculean task suddenly imposed upon the transportation lines, as a direct result of the entrance of the United States into the war, was so far in excess of anything that could have been anticipated in peace times that some allowance should be made for their temporary inability to meet it. The blame, if any, seems to rest with the American people as a whole and not with any single industry or class of individuals.

Government ownership may solve transportation difficulties, but it will be found necessary, before the problem can be classed as one of those which we have met and answered, to furnish the railroads with a much greater supply of rolling stock and motive power than they have had at any time, past or present. Judging from orders placed for new equipment this year, however, the end is not yet in sight.

As stated above, it is conceded that the entire responsibility for the coal shortage does not rest with the railroads, although the tonnage lost today through lack of cars is just as impossible of recovery as that lost through mine disability or failure of men to report for work.

It has been proved conclusively that nothwithstanding the inroads of the draft, voluntary enlistments and loss of men to munition plants, ship yards and other establishments offering special inducements, the men remaining in the industry can, if certain factors entering into the equation be given proper consideration, produce all of the coal which seems necessary at this time. The problem before us is, however, to so coördinate the various factors that the result may be obtained before it is too late. Since at least one of these factors is an unknown quantity—namely, the personal equation—any preliminary figures are apt to be subject to correction. Petty strikes and malingering by individuals who either refuse to do an honest day's work when under ground or who persistently lay off one or more days per week, are responsible for the next greatest inroad on production after lack of transportation. The first mentioned cause is difficult to control, and unless the men can be made to see that the success of our armies abroad is more vital than some paltry victory of their own over an operator, who in all probability would have gladly mediated the affair with them in the first place and thus avoided a shutdown, it may grow to be a menace to our very existence. Laying off without a justifiable excuse is also difficult to handle, although it appears to me that a stiff fine, payable to the Red Cross or some other recognized association, would in a large measure curtail the evil.

The very human desire on the part of the miner to better his condition and to try the unknown is responsible for a continuous movement from camp to camp and from field to field, with a resultant loss of man power. This, while hard to calculate, must entail a great potential loss of tonnage to the industry as a whole.

With the company with which I am connected the labor turnover amounts to from 15 to 20 per cent. per month, and I feel safe in saying that these figures will hold good for the entire State of Utah. It thus readily can be seen that if only one or two days are lost by each

individual between the jobs the aggregate loss of tonnage is considerable, even in a small producing district, such as Utah.

A system of registration under the "work-or-fight" ruling, whereby the employee would be given a card each month upon which would appear a statement from his employer showing the number of shifts worked, actual efficiency of the individual and time lost without just cause, which card would have to be submitted to someone in authority and the miner assessed a penalty for failure to work, before another card could be issued, would in a large measure eliminate this source of loss.

Drunkenness, of course, contributes to a certain extent as a cause for loss of time. However, I do not believe that the coal miners, as a class, are any more prone to drunkenness than any other like number of men in other industries. The active solicitation of men by unscrupulous operators should be prohibited. This situation could be handled efficaciously by the Federal Administrator and another leak thus stopped.

Payment of so-called bonuses by operators, whose mines are either deficient through natural causes, by lack of knowledge on the part of officials, or insufficient capital wherewith to properly equip them, should be prohibited and these mines, except in rare cases where they constitute a sole source of supply, should be closed down and the men there employed transferred to other mines where greater efficiency could be secured. Undoubtedly there are mines working thin coal beds where the output per man per day may be high under the circumstances, but it is possible that by shutting down some of these operations and concentrating the men in mines where thicker seams prevail that a much higher tonnage per man per day could be secured.

The operation of so-called wagon mines, where shipment is made by rail, should also be discouraged, except in certain instances where it might be proved that the mine was efficiently operated and did not add to the scarcity of railroad equipment by tying up cars unnecessarily. The opening of new mines indiscriminately, especially by inexperienced people, should be prevented, except in cases deemed expedient after due examination and favorable report by competent investigators.

Several new mines have been opened in the State of Utah during recent months, but I do not believe that they will add one ton to the production of the state for the current year, as the entire tonnage could have been produced by the older and better equipped properties if they had had ample man power. In some instances I believe that the new mines will result in a decrease in possible production. I judge that like conditions exist in other sections. Many old mines could be shut down for the duration of the war, and, if their employees were concentrated at more efficient properties, an increase in output would result.

The foregoing are only a few of the ways in which efficiency can be raised. However, lacking authority to put any of the suggestions into effect, it seems that we must go deeper into the subject and endeavor to find some means by which we can meet the present urgent demands. But before accepting any panacea as being the one most suited to our ills, we should be doubly sure that we are prepared to assimilate it.

We may, by friendly coöperation and admonition, so imbue our men with a spirit of patriotism that they will voluntarily enlist for the campaign, as it were, and thus furnish the additional coal necessary, so that intermittent railroad service can be obviated to a certain degree.

A plentiful supply of cars does not relieve the situation if the mine is unable to load them. Likewise plenty of men, all willing to do their bit, cannot produce any more coal than the company is prepared to take away from the face. The operator should therefore see that his house is in order before he places the blame elsewhere.

No excuse should be furnished the miner for failing to perform a maximum day's loading. The operator should see that all places are properly cut and shot in time to insure an ample supply of coal; that the tracks throughout the mine are in good shape so that the coal may be hauled with the least possible delay; that the ventilation of the mine is of the best so that the men can work without discomfort; that material usually furnished by the company, such as ties, rails, spikes, etc., are kept within easy reach of the working faces where they can be secured by the contract miners and others with a minimum of delay. The safety of the mine as a whole, as well as that of each individual, should be given constant attention, as even minor accidents tend to curtail production.

Breakdowns of machinery should be eliminated as far as possible. This can be done to a large extent by making frequent inspections and having repairs made as they become necessary. Duplicate repair parts for essential equipment should be carried in stock wherever possible, and all large mines or companies operating several mines should have facilities for making repairs on the job. These should cover everything but the largest and most complicated parts.

Mechanical devices used in connection with coal production should be of the latest and most efficient types. Inefficient equipment should be scrapped wherever pos-

Our Industrial Part

SOME observers think that the most characteristic thing about the American soldiers in France, something which astounds the enemy and excites the admiration of our allies, is the capacity of the American soldiers to do individual thinking and fighting. The German fights successfully only in mass formation, in organized bodies, while every American soldier has an initiative and independence of action which gives him remarkable efficiency in open fighting. They are not senseless cogs, but each is an individual working unit in a great fighting machine. Every American at home should feel an individual responsibility and do his or her individual part in winning the war. There is not an American citizen who can not help win the war. The Fourth Liberty Loan drive, which began on September 28, offers a great opportunity for concerted action and for individual action, and the loan will be a tremendous success if each American will do his or her individual part as each American soldier in France does his part. Our soldiers deserve such support from the people at home.

sible. Mine development should be kept in advance of reasonable production needs. Where possible, modern methods of working should be adopted. It is believed that, if all the mines in the country where such a method of operation is practicable, were worked on the retreating panel system, that the efficiency would be so increased that there would be no possibility of a shortage in production.

Almost every mine can, by the expenditure of a little money, increase the tonnage per man appreciably, and in many instances such increase could be made to run as high as 25 per cent. or greater. Such an increase in efficiency would not only go a long way toward solving the fuel problem, but would repay the operator many times over for the expenditure.

Employees and their families should be shown every consideration. Decent housing should be furnished and where possible the camps and surroundings beautified by lawns, trees and flowers. The employees should be encouraged to plant gardens and otherwise show an interest in their homes. This can only be satisfactorily accomplished by coöperation between employer and employee. Some little expense is connected with all sociological work, but the results are worth it.

A variety of colors should be used when painting dwellings, as the miner is entitled to as much individuality as any other small town dweller, and a camp painted all one color makes a poor showing as compared with one where taste has been exercised in selecting a diversified color scheme. As a small boy I often wondered why our Jersey bull had such an antipathy to red. In later life I decided that he must at one time have lived in a coal camp.

Amusement facilities should be supplied for both the miner and his family. This is a matter calling for a considerable outlay, but almost every company can well afford to expend a reasonable amount for the pleasures of their employees. This is particularly true in isolated camps. The education of the children should be well looked after and the school buildings should be equal to those maintained in similar centers of population in the surrounding district.

A place for religious services should be provided, and where a sufficient number of more than one denomination obtains, separate buildings should be maintained, if at all possible.

If it were feasible to adopt even a few of the above suggestions, we would be much closer to that Utopia for which even the coal miner is entitled to crave, and thus many of the problems which confront the industry would be automatically solved.

Mine Safety in Wartime

By D. Harrington
U. S. Bureau of Mines

THE feverish wartime demand for maximum output from the mines, coupled with the accompanying relaxed discipline arising largely from a shortage of labor, has in many portions of the country resulted in greatly decreased effectiveness of safety organizations and their work. This situation is not so readily apparent in regions which in the past have not had strongly organized safety work, but in those localities where a few years ago efficient safety inspections and regulations, were in effect and good records made the ill effect of present abnormal conditions is readily apparent. This is exactly as it should not be. Mine accidents not only result in suffering and expense to the victims and to the operating companies, but also the general public and the progress of the war are unfavorably affected by the loss of output not alone of those who are injured but also of other mine employees whose time and attention are occupied by the accident.

Definite statistics are not at hand as to the total amount of time lost in our mines due to accidents; however, we know that well over 2000 coal miners are killed annually in this country at this time, and a conservative estimate of the total amount of time lost due to accidents by our three-quarter of a million coal miners would aggregate at least three or four million shifts annually, with the resultant loss of at least 10 to 15 million tons of coal production.

Immense strides toward safer methods of mining have been made during the past ten years. This is well shown in the number of men killed in major coal-mine disasters, the reduction being both steady and rapid; in 1913, 464 men were killed in major disasters in the coal mines of the United States. This record was reduced to 316 in 1914, 262 in 1915 and 154 in 1916. While much progress has been made we still have with us many men of the old school of coal-mining, who insist that the safety movement is a "fad" and whose mines may in general be relied upon to be about as dangerous as they can be and yet "get by" when the state inspector comes round.

The employment in positions of authority or as safety inspectors of men whose sole qualification is many years of experience in mining, who frequently have little or no education and not much judgment, is one of the greatest obstacles to safe and efficient mining existing at the present time. Men of this type only too frequently think no mine should be considered gaseous unless it has had a major explosion, that dust cannot ignite or explode unless gas is present, that first aid is an "old woman's idea," that one air shaft is enough for any mine, that the "eating" of a certain amount of powder smoke will prolong the miner's life, that in fact conditions and methods of 20 or 30 years ago are applicable today. The time has arrived when men of this type should be used only in subordinate positions, leaving the decision of vital questions to the educated man with five to ten or more years of experience and with ability to observe and absorb present-day progressive methods.

Every mining company should have a well defined, active safety organization. Small companies cannot

He Has Given You Everything You Have

afford to have men employed exclusively for safety work, but they should have superintendent, foremen and bosses banded into a formal association with a definite head, with stated time to get together to discuss measures looking to safety (and possibly to efficiency). Some member should be designated to record data as to all accidents occurring, this data to be compiled from time to time and studied and analyzed with a view to determining causes of accident and best methods of preventing repetitions. Companies employing 1000 men or over will undoubtedly find that it will pay financially to have a man or men all of whose attention is paid to safety work, including inspections both on the surface and underground, following up accidents, keeping accident sketches, records, etc., compiling and analyzing such records, and possibly giving instruction in first-aid methods. It is recommended that the accident-record form of the United States Bureau of Mines be adopted with such modifications as may be deemed necessary, these forms being the result of many years' work and the experience of a number of authorities on mine-accident statistics.

That it pays in dollars and cents to have safety organizations can be seen by the number of mining companies that maintain such organization since the passage of workmen's compensation laws. One large mining company established a safety organization consisting of several men, and during the first year of its existence the number of fatal and serious accidents was reduced over 30 per cent. as compared with the previous year. During the next year the record was reduced by another 20 per cent. as against the first year of safety work. (In the foregoing a serious accident is considered as one incapacitating the victim for 14 days or over.) In another region a large company having a comprehensive safety and welfare organization had a record of producing nine times as many tons of coal per fatality as the average of nine other companies producing in the same field and under essentially similar natural conditions, the other companies in general making sport of the "fads and fancies" (as they styled them) of the company with the good fatality record.

While education of miners in safe and efficient methods of working is of immense ultimate value in reducing accidents, it appears that the results are slow and for immediate present-day effect the use of penalties and bonuses, together with educational work, give the best satisfaction measured in quick returns. It is found that many bosses give only indifferent coöperation in the enforcement of safety rules unless offered some incentive such as cash or some other prize for having a good accident record or for excelling the record of other bosses or departments; these prizes should be given to all bosses actively concerned in underground work, but coupled with the prize or bonus system there should be a penalty system assessing loss of money or time for non-compliance with safety regulations. The miners and other day or contract and underground employees can best be handled as to safety by penalizing them for the infraction of safety rules by a "lay off" or money fine on one hand (the money to go to some charitable purpose such as the Red Cross), and by giving prizes or bonus for keeping a place safe, for being at work a maximum number of days per month or for cutting or loading a maximum coal tonnage per month or per year.

Will You Lend It Back To Him?

It may be insisted that assessing penalties is out of the question with labor in its present state of independence. Yet if the penalty is assessed for the purpose of protecting the man from accident he cannot object seriously while the departure of an unsafe man is to be desired rather than deplored. A large portion of the present relaxation of discipline is due to over-anxiety of employers to retain labor and to draw it from neighboring enterprises. If employers would reassert themselves (as they should) in regaining control of the discipline which existed even a few years ago, it is probable that little real opposition would be encountered, if the effort was made in a tactful way. I have in mind several serious accidents in mines during the past year brought about by the victim's performance of acts which he would not have attempted two years ago because of knowledge of punishment certain to follow.

Lack of supervision is one of the most potent sources of accident and indeed of loss of life and of property in mines. The fireboss who is compelled to run through his "beat" in order to cover the territory assigned him is absolutely unable to perfom his inspection in an efficient manner. There should be sufficient firebosses to every mine to allow of the spending of at least a few minutes at every working face and to permit of walking between places. To do this the fireboss may be compelled to spend more hours underground than at present, and possibly there would be required an increased number of firebosses.

Shotfirers, too, should not be allowed to light fuses on the run, as is frequently done. In general the shotfirer should be compelled to inspect the hole and load and fire all charges. Where holes are loaded by miners the shotfirer should be required to remain underground a sufficient length of time to allow of firing all shots in a thoroughly safe manner.

Especially in the pulling of pillars should ample supervision be supplied, and a pillar boss of ability and force of character can in general more than save his salary in the recovery of props, rails, ties and coal as well as enforce safe and sane methods of work. In general, such a boss should not be required to have in charge more than 20 to 30 men, and these should be in a somewhat confined region. At this time, when extremely high rates allow miners to accumulate in a few hours what was formerly a day's wage, the miner is only too likely to seize on any convenient excuse to leave his work. Frequently, if a "straw" boss is at hand the deficiency complained of may be supplied quickly, the miner's pretext for leaving removed and the miner held

at his post. Where miners are under written agreement to remain at work a certain number of hours per day, the presence of a boss over a limited number of men will keep these men at their places whereas in mines having but one foreman and no other sub-bosses, the miners will probably leave work hours before the agreed time.

In one coal-mining locality where subscription quotas for Red Cross, Liberty Loans, Thrift Stamps, etc., were promptly and largely oversubscribed, and where miners or other camp employees even suspected of shirking in the slightest degree any of the ordinary war time responsibilities were summarily treated by the miners themselves, the amount of coal mined per man employed by the company fell from 5.03 tons per day in 1916 to 3.08 tons per man per day in 1917. This decrease in efficiency took place at a time when demand for coal was urgent and when labor was scarce, and the cause was wholly uninfluenced by any change of conditions except that the high wages of 1917 enabled the contract miners to work three to five hours per day and then have earned $7, $10 or $13, or even more, whereas in 1917 they would have remained a full shift to earn that amount. Had the company placed a sufficient number of sub-bosses in charge these men could have been compelled to adhere to their signed agreement to work eight hours per day. Moreover, this would have prevented the danger to life and limb caused by the traveling of haulageways by large numbers of contract men during working hours.

Buy a Bond—Loose the Eagle

The disinclination of miners and mine officials to change from old methods to newer and safer ones results in perpetuation of many dangerous and inefficient practices. Only too frequently is progress met with the statement "It can't be done," this statement often carrying the inference "It won't be done." In one large metal-mining district where lighting was by candle and numerous enormously expensive disastrous fires and accidents were traced directly to their use, a recommendation for substitution of carbide lamps was ridiculed by miners and mining officials alike; yet within a year candles were practically discarded and the lighting cost reduced at least 30 per cent.

In a coal mine shooting coal off the solid, using black powder, numerous explosions occurred until undercutting machines and permissible explosives were introduced; because the machines caused considerable trouble and expense for upkeep and because machine runners were hard to manage, the foreman and superintendent threw out the machine, though the total cost off coal had been reduced and the percentage of lump coal increased by use of machines. In less than a year after discarding machines and permissible explosives from this mine and returning to black powder and shooting off the solid, a disastrous explosion occurred in which two lives were lost and one-half of the mine wrecked so badly that it required several years and the expenditure of nearly 100,000 to reopen it.

This disinclination of mining men to change from obsolete practice to safe modern methods annually costs many lives and frequently results in loss of much property and of entire mines. Although almost any progressive mining man realizes the danger of ventilating even a non-gaseous mine (especially a large mine) with but one air split, yet one can find gaseous mines in many sections of the country with but one ventilating current sweeping the entire mine. Again, while it has been demonstrated repeatedly that by the use of panel mining, ventilation, fires and even explosions can be readily controlled, yet one finds entire coal fields worked on the same dangerous and extravagant system of 20 years ago, even though the natural conditions are admirably adapted to modern panel mining. It is unfortunate that even in some mines that are safe in many particulars occasional practices are allowed through carelessness or ignorance which nearly nullify the safe features.

Mines which undercut all coal by machines are found leaving the cuttings under the coal to such an extent that the shooting is essentially on the solid. In other cases the coal is undercut and permissible explosives used for the sake of safety, yet the holes are charged with seven to nine sticks (3½ to 4½ lb.), thus practically doubling the safety limit set for the amount of permissible explosive per charge. The same total amount of explosive could be employed in a perfectly safe and far more efficient manner by the drilling of a few extra holes.

Frequently operating companies allow efficient methods or practices to become dangerous and wasteful through lack of even occasional inspection or supervision, or through carelessness or even deliberate intent to discredit such methods or practices by under-officials or employees. An explosion was alleged to have been caused by shots in a coal mine supposed to be using permissible explosives exclusively. It was afterward discovered that a miner had inserted some 40 per cent. dynamite into the hole before the shotfirer came around to place the permissible explosive.

Although miners, by working three to five or six hours per day underground, are now earning wages which allow of ownership and operation by them of high-class automobiles, yet they are often disinclined

to do their work in a safe, efficient manner. A mine manager in a mine using permissible explosives complained bitterly of the increased percentage of slack coal and blamed the explosive. Upon investigation it was found that instead of the slack from undercutting by electrical chain machines, being removed, practically all such material was allowed to remain under the coal due to the laziness of the machine men. Hence this coal was shot essentially on the solid. Moreover, instead of using seven or eight holes, each charged with 1 to 1½ lb. of permissible explosive, to bring down a room face as had been the previous practice, four or possibly five holes were employed, each charged with 2 to 3½ lb. of explosive.

Furthermore, instead of firing the "buster" shots and loading out the loose coal before loading and firing the other holes, all the holes were loaded and tamped before any were fired; and when firing was started, it progressed to completion before any loading out of coal was attempted, even though frequently practically all the work of a loaded hole had been done by one already shot. When this situation was brought to the attention of the mine officials they said they had been too busy to look after such details.

One of the effects of the present prosperity of the miner, especially the coal miner, is a disinclination to take time for training in first-aid methods. Bureau of Mines representatives have much difficulty, especially in some parts of the coal-mining regions of the West, in obtaining men to whom to give training in first aid. In some places no active opposition is encountered, but comparatively few men appear for training; in other localities the instructors are told that the miners have been "first-aided to death."

Generally, first-aid training is given by Bureau of Mines instructors at night in order to avoid interfering with mine operations, and the miners are expected to take the training in first aid without being paid therefor. Nothwithstanding the heavy earnings of coal miners at this time, they seem to be disinclined to take training unless paid by the companies to do so, though in general the miner rather than the company is the beneficiary.

As an instance of the effectiveness of first-aid training for coal miners, the men of one coal mine were trained in first-aid methods and practically all injured men come out of the mine well bandaged. The men and management of an adjoining mine working the same coal bed and having practically identical working conditions gave no attention to first-aid practices, and little or no bandaging of injuries was attempted other than using old-fashioned methods. The doctor in the latter camp complained bitterly of infection of wounds, stating that hundreds of shifts of work were lost by men in his camp annually due to infection of trivial wounds, while at the camp using first aid freely there was practically a total absence of infection. War times are made an excuse for the existence of all kinds of unsafe and uneconomical practices. Notwithstanding the passage of an act to safeguard the sale, use and storage of explosives, unsafe practices and conditions both on the surface and underground are only too frequently found. Lack of men or of material or of money are alleged as a cause for non-compliance with regulations. Electric wiring is rapidly increasing underground, and many of the electrical installations are extremely dangerous. Among these might be mentioned fastening wires to posts by nails or wire or rope, setting motors on timbers that soon become oil-soaked and placing switches on posts or flimsy timber partitions. Lack of men or material is given as the reason for such admittedly dangerous conditions. Moreover, many mining companies claim that no improvements or changes should be made now, giving generally as a reason that all men should be kept on coal production. They forget that a fire or explosion caused by dangerous conditions or practices may cost many lives and result in loss of the entire mine.

On the other hand, some companies are taking advantage of high earnings to fortify their mines as to future safety. One large metal-mining company has recently embarked on a ventilation program which contemplates an expenditure of over $1,000,000. This firm has ordered surface fans with a total capacity of over 3,000,000 cu.ft. of air per minute, and in addition will have over 300 new small booster fans for underground service. This company wishes to improve the underground conditions while earnings are large and at the same time be prepared with the best possible working conditions to compete with its rivals when selling prices drop after the war.

It is quite noticeable that small mining companies in general give much less attention to safety than do the larger ones, and in general the accident record of the smaller companies is not so creditable as that of the large concerns. State mine inspectors are almost unanimous in the opinion that small mines and mining companies are much more reluctant to obey the state laws than are the larger concerns. This is somewhat unfortunate and makes the task of the inspector difficult, causing officials of the smaller concerns to charge favoritism on the part of the inspector, when as a matter of fact the real difficulty lies in the non-progressiveness of the smaller concerns themselves.

Safety men, including state mine inspectors, frequently find that their most difficult problem is to impress the advisability of safe practices upon the miners that they wish to protect. On the other hand, only too frequently mine officials are prone to carry out the letter and forget the spirit of safety practices. At time of explosion or other disaster resulting in loss of life, the local management is generally demoralized or disorganized and incapable of acting or thinking efficiently. Moreover, operating officials seldom have had experience at disasters.

The state inspector, on the other hand, has had (or at any rate should have had) experience at disasters, has a general knowledge of the mine and its personnel and is not likely to be personally affected by the death of people who are probably strangers to him. While the company officials should be on the ground to aid and assist in every possible manner, the direction of the rescue and recovery work should be absolutely in the hands of the state inspector, and state laws accordingly should be amended to give inspectors absolute authority at times of disaster. The foregoing comments are general and meant to be constructive in nature.

Minecdotes

Bow Dougherty's Ghost

Bow Dougherty was one of the most superstitious of men. The existence of ghosts and banshees was to him a grim reality; and judging from his numerous stories, he had had a world of experience with spirits of all kinds. He always admitted, however, that each new ghost scared him quite as badly as on the first occasion. Personally, the writer has never seen a ghost; on one occasion, however, I have seen Bow while suffering from the effects of a ghost scare. To me it was very amusing.

It was an idle day at the mine and several of us had been sent to do some trackwork. At noon the fireboss came along to see how the work was progressing, and as usual Bow was relating some ghost story. Dinny Curley, the fireboss, was a practical joker, and, while he was a good official, seldom missed an opportunity for fun. After we finished eating, he called me to one side and told me to wait 20 min. and send Bow to the face of the gangway for track spikes. In the meantime he went out of the gangway, climbed up an outside manway, thence to the airway and down an inside manway to the face of the gangway. After shedding all his clothing he hid his oil lamp and waited for his victim. When Bow was within a few hundred feet Dinny turned his back toward him, bent his body forward and waved the light slowly from side to side between his legs. One look was enough for Bow, and in less time almost than it takes to tell he was back with us. To say he was scared would be describing his condition mildly. We expressed doubts as to the veracity of his statements and insisted on accompanying him to investigate, but there was only one direction in which he would go willingly.

In the meantime the fireboss had retraced his steps and when he again joined the group Bow retold his story. The fireboss listened with considerable interest and then, thinking to set him right on the ghost question, told him it was he and not a ghost he had seen in the gangway. Before he could explain, however, Bow exclaimed: "Go wan, now, Dinny, you can't make me believe that." Then, holding his hands in front of him, and about two feet apart, he continued, "The ghost I saw in there had a face on him that wide."

Great Britain's Fuel Research

By Mark Meredith
Liverpool, England

It is in the highest degree satisfactory to know that the whole question of the proper use of Great Britain's fuel resources, and of the practical problems which must be solved if any large proportion of the raw coal which is at present burned in its natural state is to be replaced by the various forms of fuel obtainable from coal by carbonization and gasification processes, is to be made the subject of authoritative national investigation, and that a fuel research station on an adequate scale is to be established for the purpose. All the arguments are in favor of the pre-carbonization of coal. It would centralize power generation, free our towns of smoke and dirt, yield valuable byproducts now burned to waste, provide large quantities of liquid fuel, and conserve the national fuel resources.

The practical difficulties are enormous, many private syndicates have found to their cost, and no really comprehensive scheme can be formulated, much less carried out, until certain definite problems in coal, power and byproduct distribution have been solved. A great amount of experience and trustworthy data are available in regard to the high-temperature carbonization as practised in connection with the manufacture of gas and metallurgical coke, but as regards the carbonization of coal at low temperatures there is no corresponding body of experience in existence, and few properly accredited data are available.

The British fuel research committee accordingly sees a way clearly open for a serious attempt to determine whether an economical and efficient apparatus can be devised for the carbonization of coal at low temperatures, and whether, by the use of such an apparatus, for the carbonization of properly selected coals, products will be obtained of a collective value greater than that of the original coal plus the cost of carbonization and handling. Nor is it merely a question of process and products; but there has also to be considered whether profitable outlets for the products can be found. It is for the purpose of making a full experimental investigation into the whole question that the fuel-research station at East Greenwich is to be built, and it will be designed and equipped in such a manner that operations on an industrial scale can be conducted under working conditions.

German Pre-War and Present Coal Prices

A remarkable advance in the prices of coal has taken place in Rhenish-Westphalia since the outbreak of the war. For the first time since the beginning of hostilities, according to the *Iron and Coal Trades Review* (England), the German newspapers have published a comparison of the prices charged by the Westphalian Coal Syndicate in the autumn of 1914 and those which came into operation on Sept. 1 last. These quotations are the so-called "guiding prices" which are charged to the merchants, who base thereon the sale prices which consumers have to pay and which are consequently substantially higher than the former, as they include merchants' and dealers' profits, the cost of transport, etc. As given by the German newspapers the comparison of the guiding prices is as follows, the quotations being for coal at the mines:

	Guiding Prices at the Mines on	
Bituminous:	Aug. 1, 1914	Sept. 1, 1918
No. 1 lump	$3.33	$7.17
Washed No. 1 nut	3.39	7.41
Washed slack	2.29	5.93
Coking coal	2.97	6.79
Gas coals:		
No. 1 lump	3.33	7.17
Washed No. 1 nut	3.39	7.41
Small, over 30 m.	2.24	5.94
Small unwashed	1.73	5.19
Semi-bituminous:		
Lump	3.46	7.17
Washed No. 1 nut	3.96	7.91
Small unwashed	1.73	5.19
Coke:		
No. 1 blast furnace	4.20	9.14
Foundry	4.21	9.15
Coke breeze	2.65	3.97
Briquets:		
No. 1	3.39	7.66

W. J. MURRAY

By Floyd W. Parsons

IN the death of W. J. Murray, vice president and general manager of the Victor-American Fuel Co., the State of Colorado loses the dean of its coal-mining industry. Not many men at the finish of their life's work will leave a greater host of friends, a cleaner record of deeds performed, or a better example of strong manhood than did Mr. Murray. His life is an inspiration to all of those ambitious souls of foreign birth who have left the land of their nativity to make a place and a name for themselves in this free country of unlimited opportunity.

Few men were possessed of greater courage than was he, but his boldness had eyes as well as arms. Not many individuals were more blunt in speech, but his very directness in getting straight to the heart of a matter was one of his principal virtues, for those who dealt with him soon learned that they would not have to waste time in getting his opinion in any matter. Underneath his rather stern exterior was a heart tender in its affections and a degree of loyalty that one could seldom meet. His friends were not picked at random, nor were they selected in a moment. It required time to win a place on his list of intimate acquaintances.

Born in 1852, in the County Durham, near Newcastle-on-Tyne, W. J. Murray entered his first employment early in life in the coal mines of England, where he worked until he left the British Isles at the age of 21 to come to America. The mines were a very real memory in his life, for both his father and brother were killed in a mine accident prior to his coming here. This early disaster, however, did not discourage his ambitions in the line of mining, and only made him the more determined to conquer the physical dangers and the hidden forces that surrounded his chosen vocation.

On arriving in the United States, he spent a short time in Pennsylvania, and then headed for Leadville, Colo., where he worked in the silver mines several years. Leaving the metal mines, he again took up coal mining, locating at Crested Buttes, Colo., and the rest of his life was devoted to this business, which he first chose when a lad in England.

In 1882, Mr. Murray married Martha E. Young, who, with five of his children, survive him. W. F. Murray, his eldest son, is now engaged in coal mining in Colorado, while his other boy is at Camp Hancock in his country's service.

In 1887, "W. J.," as he was familiarly called, entered the service of the Colorado Fuel and Iron Co., as superintendent of that corporation's mine at Sopris, Colo. Twelve years later he was appointed division superintendent for the same concern, remaining in this latter position until 1903, when he went over into New Mexico to accept a place as general superintendent of what is now the St. Louis, Rocky Mountain & Pacific Coal Company, at Raton. Two years later he entered the service of the Victor-American Fuel Co., being employed first as general superintendent, then general manager and finally chairman of the executive committee, which latter position he held at the time of his death at La Jolla, Cal., Sept. 11, 1918.

He was associated with J. C. Osgood, founder of the Colorado Fuel and Iron Co., for more than 30 years, and no man in the Rocky Mountain country has done more than has he to advance the science of mining in our western fields. Mr. Murray was a member of the North of England Institute of Mining Engineers, a former vice president of the Rocky Mountain Coal Mining Institute, a Shriner, Knight Templar and a Thirty-second Degree Mason.

I worked for and with him more than a dozen years ago, and as time passed my respect for the man steadily grew, until in his death I feel that the coal fraternity to which we all belong has suffered a loss that cannot be replaced. He was one who never fed arrogance or conceit with supple knees, nor was he deceived by the surface veneer of an empty pretender. His entire energy was devoted to vigorous execution, and he wasted no time in evasion and postponement.

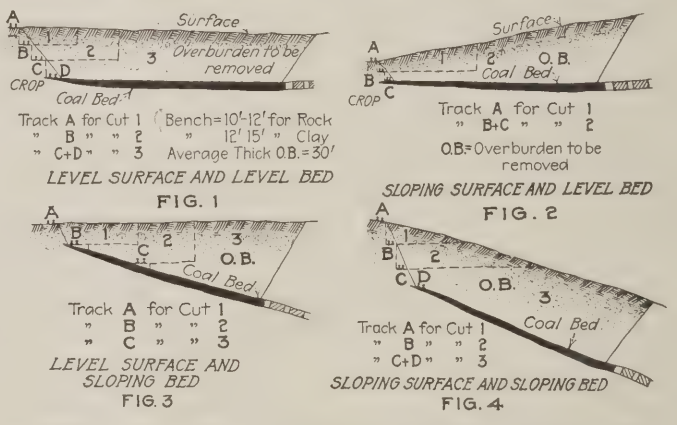
Fortune's chariot did not roll easily for him in the early years of his career, but just as every light has its shadow and every hill its valley, so has every life its reward for honest perseverance, and his efforts were eventually crowned with no mean degree of material success. But far above property, which at the best is only temporal gain, is the force of a good example which lives on in the characters and conduct of those that follow. W. J. Murray's life, above all else, taught the virtue of simplicity and modesty. There was no room in his mind for the pettiness of personal vanity. He had reduced life to its minimum of essential needs and thereby had raised it to its maximum real power.

May we all leave such a splendid autograph on the hearts and characters of our associates as did he. May we surround ourselves with such influences that will hold us up as straight and strong in the days of trial. Then will we end our work and attain the only worth-while reward which comes in the self-consciousness of duty performed.

Anthracite Coal Stripping*—V

By THOMAS F. KENNEDY
Scranton, Penn.†

SYNOPSIS—*The best method of removing overburden from coal depends upon many circumstances but should be decided before the contract is drawn or operation is commenced. The space available for dumping may be (and frequently is) an important factor. The contract for stripping should be carefully drawn and contain as few ambiguities as possible.*



ONE of the most perplexing questions facing the engineer and the contractor in an anthracite coal-stripping problem is the method of removing the overburden. This paper will be limited to a brief but general discussion of the principles involved in the solution of this broad question. In general, anthracite coal strippings may be classified under three divisions—namely, crop, anticlinal and synclinal, the latter two being often termed hogback and basin respectively. These three divisions are subdivided according to the pitch of both bed and surface as follows: Crop—Level surface and level bed (see Fig. 1); sloping surface and level bed (see Fig. 2); level surface and sloping bed (see Fig. 3); sloping surface and sloping bed (see Fig. 4). Anticlinal—Level or sloping surface and anticlinal bed (see Fig. 5). Synclinal—Level or sloping surface and synclinal bed (see Fig. 6). With few exceptions, most of the strippings will fall under one or another of the foregoing types.

Before the method of removal of overburden can be decided upon the contractor, in coöperation with the engineer, should make a thorough study of the most important details of the problem such as the plans and specifications, amount and nature of excavation, strike and pitch of bed, surface topography, available dumping ground, drainage, water and fuel supplies, labor, and access for steam shovel and other equipment to the stripping area.

After an exhaustive study has been made, the problem resolves itself into the following: The removal of the necessary amount of material to expose the largest quantity of coal in the least time at the least expense. No set or fixed rule can be used in arriving at such a result, as each stripping problem has its own peculiar characteristics. In a fair-sized stripping proposition the contractor, if inexperienced, should employ the services of a competent stripping engineer.

In the removal of overburden several means of excavation have been used with good results, but the most economical and practicable, and the one recommended ordinarily, is the steam shovel, which has precedence over other types of excavating machinery. Electric shovels, however, have been used with good results. A few suggestions as to probable methods of removing overburden are shown in the accompanying cross-sections of typical strippings now under operation in the upper anthracite coal region. In many instances surface features will control the method of procedure in starting the cuts. Strippings in the upper anthracite region have an average overburden thickness of 30 ft. with few exceptions.

Fig. 1 shows a series of cuts whose total sum of vertical heights amounts to approximately 30 ft., which is considered the maximum height of clay cut. In solid rock, cuts 10 to 12 ft. deep seem to be the most economical. In such instances the small steam tripod drill can be used effectively in breaking up the rock into sizes that can be handled easily by the steam shovel. Jackhamers are sometimes used for reducing the larger masses of rock. In clay and soft shale, cuts up to 30 ft. can be handled economically. In soft shale rock the churn drill can be used advantageously. Holes 30 ft. deep can be drilled cheaply, and when properly charged and fired these do effective work in breaking down the shale into sizes small enough for the shovel to handle.

FIGS. 1 TO 4. RELATION OF COAL BED TO SURFACE

In Fig. 1, cut No. 1, or the first cut made, is known as the thorough cut, which often involves a question of drainage. The type of steam shovel used determines the depth and width of a cut. A 10-ton Bucyrus with a 2½-cu.yd. dipper is capable of making a cut 10 ft. deep and 40 ft. wide. Special shovels may be made for special work. The path of the shovel in most cases follows the strike of the underlying bed. The overburden should be so excavated as to reduce the number of moves of the steam shovel to a minimum. This detail is important since moving a shovel is a waste of time and money.

After cut No. 1 has been completed, stripping limit to stripping limit cut No. 2 is made, leaving a bench for a track as shown. In rock work benches are 10 to 12 ft. wide, while in clay their widths are 12 to 15 ft. Cut No. 3 is made over the whole stripping. If the thickness of the overburden exceeds 30 ft., the 30-ft. cut is made over the entire stripping and the same operation is followed out as in the beginning. Fig. 8 shows the method of making the cuts here described.

*The fourth article of this series appeared in the March 2, 1918, issue of "Coal Age."

†Now First Sergeant, Sanitary Corps, United States Army Water Purification Detachment, 301st Water Tank Train, Camp Holabird, Maryland.

The shovel has completed cuts No. 1 and No. 2 and is working in No. 3 cut. Benches for the tracks can be plainly seen on the left of the shovel.

The main object of making the preliminary cuts is to arrive at such a depth that the shovel can work most efficiently. Since the steam shovel cannot remove

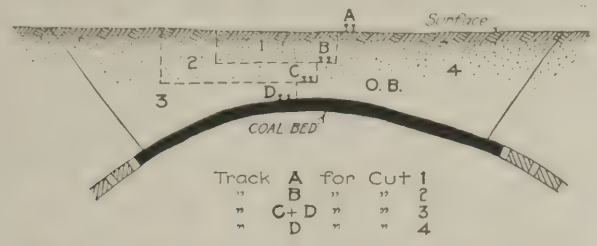


FIG. 5. LEVEL SURFACE AND ANTICLINAL BED

all clay, etc., from the top of the coal bed, hand cleaning with pick and shovel is used.

In Figs. 2, 3, 4, 5 and 6 it will be noticed that the principle involved in the method of excavation is the removal of overburden, so as to expose the coal as soon as possible for mining. The question of removing all of the overburden before coal mining is begun is often considered, but coal in the ground is money tied up, so immediate mining in most cases is resorted to. Fig. 9 shows a 70-ton Bucyrus 2½-cu.yd. shovel removing overburden 18 ft. in thickness in which a thorough cut and a finishing cut were made. The top of the coal bed can be seen in the foreground. The working direction of the shovel is parallel to the strike of the bed.

Cross-section and plan, Fig. 7, shows a side hill stripping where the overburden is transported by means of a plane to a restricted dumping ground located above the strip pit. This type of problem involves the consideration of starting to dump at the proper elevation and also of sufficient area for dumping purposes. Knowing the approximate amount of overburden in the solid and the swelling and shrinkage of the same, the total volume of excavated material can be calculated, so that the dimensions, height, top and bottom bases of the dump may be determined and the proper elevation and the

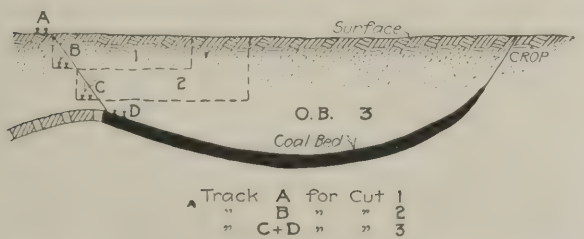

FIG. 6. LEVEL SURFACE AND SYNCLINAL BED

point of dump commencement are then fixed upon the dumping area.

Since the adjoining properties and underlying coal beds may be affected by dumped material such as the rolling of large boulders upon the properties and increase of pressure upon the surface beds under the dump, this phase of the problem should be studied thoroughly. The dumping ground question is highly important, and the dump should be so located and be of such size that the total material removed can be handled economically.

The drainage question should be investigated before actual excavation begins. There are three practical methods of drainage connected with a stripping problem—namely, natural, pumping and subterranean or mine drainge by means of a borehole or some other opening leading to the workings of the bed which is being stripped or to those of an underlying bed. Many of the strippings in the anthracite coal region solve the drainage problem by the last method. It might be stated that when the last method is used the amount of drainage should be calculated so that the mine pumps handling it together with the other mine water should not be overtaxed and so cause damage by flooding either live or abandoned workings.

In the anthracite coal region there are two general practical methods of removing coal—namely, by hand and with machinery or steam shovel. The selection of

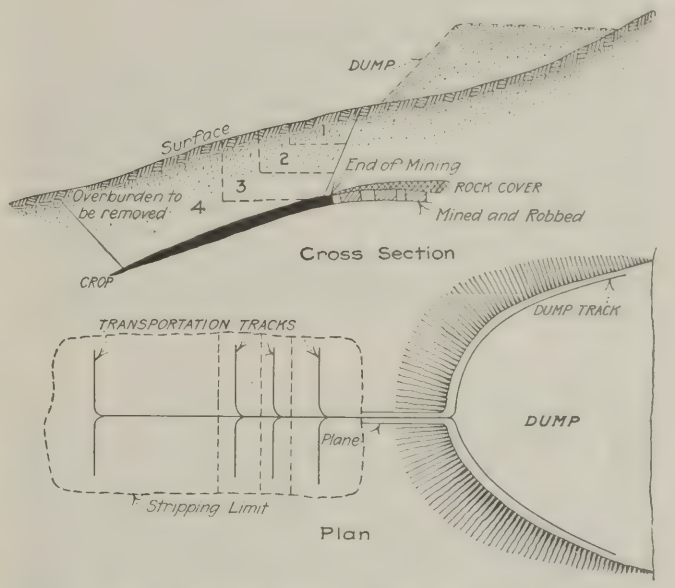

FIG. 7. CROSS-SECTION AND PLAN OF A SIDEHILL STRIPPING

either depends upon the relative or comparative economical advantages of each. For example, the steam shovel may be used in removing a bed 9 ft. thick more cheaply than ordinary hand mining, while in a bed 4 ft. in thickness the hand method would be preferable. Fig. 10 shows a basin stripping, where a 20-ft. coal bed is loosened by shooting. With the aid of a ¾-cu.yd. Marion steam shovel and small plane the coal is transported to the breaker. Fig. 11 shows a coal bed 4 ft. in thickness which, having been stripped, is being mined by hand methods of drilling, shooting and loading into the cars for transportation.

In connection with the mining of a coal bed 10 ft. in thickness or over, a churn drill may be used in drilling holes for shooting purposes. In a stripping proposition on a coal bed that has undergone its first mining the steam shovel is often used to advantage, because under such conditions there is mixed with the pillars an additional large amount of dirt which must be handled. In such a case the contractor and engineer should make comparative estimates of costs of both the hand and steam-shovel methods.

In connection with the removal of overburden and coal the important question of the contract arises. The

universal practice of the operators in the anthracite coal region is to let the work of removing the overburden on a contract basis to an outside contractor, while the coal is usually removed either by a steam shovel run under the direction and charge of a company foreman with the necessary laborers or to a contract miner who usually uses the hand method of mining. There are several reasons why foreign interests such as the contractors are involved in stripping. The company as a rule has no such well built-up organization as that of the contractor whose years of experience ultimately produce the more economical results for the company.

The usual form of a stripping contract is an agreement between the competent parties, the company or individual operator and the contractor, whereby a certain number of cubic yards of overburden or tons of coal are to be removed within a certain time at a certain price per cubic yard. Care should be taken in writing up a contract that only essential terms, conditions, etc., are mentioned. Ambiguity should be avoided; statements should be clear and forcible. Each article of the agreement should be specific, definite, concise and not a conglomeration of sentences having no direct connection with the article itself.

Although each stripping contract has certain terms, conditions, etc., peculiar to itself, the following essential points should be considered and are generally present in every ordinary stripping contract. In drawing up the contract the salient feature is the introductory agreement between the company or individual operator (the party of the first part) and the contractor (the party of the second part), to strip the overburden overlying a certain coal bed in a certain locality within definite time limits in accordance with definite plans, specifications, terms, conditions, etc. Maps and cross-sections showing the location of the stripping limits, approximate number of cubic yards of overburden to be removed and other vital features bearing upon the problem should be attached to the contract proper. The compilation of the contract then develops under two general heads—namely, those articles that have a direct bearing upon the actual removal of the overburden, while the second division covers conditions and terms in general.

Under the first division the following points are highly important: (1) A general description of stripping; (2) the number of cubic yards of overburden to be removed; (3) the stripping limits of area; (4) the average thickness of overburden; (5) the approximate percentages of rock and earth; (6) kind and number of excavating machines; (7) definite number of cubic yards to be removed monthly; (8) price of excavation; (9) classified and unclassified material defined; (10) payment per cubic yard in place; (11) nonpayment for excavation other than that specified; (12) cleaning top of coal bed; (13) extras and method of payment; (14) final estimate.

FIGS. 8 TO 11. ILLUSTRATING SEVERAL METHODS OF REMOVING OVERBURDEN AND COAL

Fig. 8—Method of making cuts for removal of overburden; benches on left for track; shovel working in third cut. Fig. 9—Bucyrus shovel (70-ton) removing all overburden, 18 ft. thick, after making the preliminary cuts; top of coal bed in foreground. Fig. 10—Showing removal of coal in bed, 20 ft. thick, by a Marion ¾-yd. shovel and plane, for transportation from basin stripping. Fig. 11—A bed of coal 4 ft. thick being mined by hand method

The second division covers the following points: (1) Provision of the equipment and the necessary diligence by the contractor; (2) water and fuel questions; (3) erection of necessary buildings and sanitation; (4) owner's right to mine coal at any time; (5) subletting of contract; (6) experienced foremen required; (7) payment of rates to employees; (8) insurance and workmen's compensation; (9) damages in case of hindrance to work; (10) suspension, failure to prosecute work; (11) disputes; (12) mechanic's lien; (13) general specifications, relating to definitions of engineer, coal company, contract misunderstandings, certi-

fied check and bonds, award of contract, unit prices used, quantities paid and the necessary signatures and legal questions involved.

One highly important article of the contract is the definition of classified and unclassified excavation. Classified material is generally divided into two divisions—namely, earth and rock. Sometimes it includes culm and loose rock, which often composes some of the overburden in a stripping proposition.

A certain contract disposes of these questions as follows: "Earth shall include clay, sand, gravel, loam, slate and decomposed disintegrated coal, stone and boulders, containing less than 1 cu.yd.; also stratified solid sandstone in layers of 8 in. or less in thickness when separated by earth as defined above and all other material not classified under rock. Rock shall include all solid slate and sandstone in place in layers greater than 8 in. in thickness, whether or not it is separated by layers of earth as defined above and all boulders containing more than 1 cubic yard."

Loose rock and culm are sometimes defined where local conditions are such that the earth and rock are so classified as not to include these materials.

Stripping operations are often handled inefficiently and with disastrous results due to many causes, of which underestimating is the chief. Underestimating arises chiefly from lack of training and experience, lack of test-pits and borings and cost data, probable future changes, fluctuation in wages and prices of materials, incompetent foremen, plant removal and depreciation, accidents and too small a margin of profit, both on material and labor, also possible legal expenses.

In conclusion, the contractor must have not only the hearty coöperation of the company and its representatives, but also the untiring interest of his organization before the best results can be produced.

Hinckston Run Mine of Cambria Steel Co.

By William E. Winn
Pittsburgh, Penn.

The Cambria Steel Co. has commenced the groundwork for a tipple, coal-conveying system and coal washery at its Hinckston Run mine, adjacent to Johnstown, Penn. This plant will furnish the main supply of prepared coal for the adjoining byproduct coke ovens, now under construction and known as the Rosedale Coke Works. The final plant will take care of a mine output of 6000 gross tons per day, or 36,000 tons per week. Of this amount 21,000 gross tons per week will be washed for coking use, while 15,000 tons will be crushed and then partly cleaned by a Bradford coal breaker for boiler, coking and producer use. The present installation will be one-half of the ultimate plant.

The coal-screening, crushing and washing machinery will operate six days per week, ten hours per day, and the traveling coal-handling bridge, which reclaims coal from the drainage pits and deposits it in the lorry bins, will operate seven days per week, ten hours per day. A belt conveying system will be designed to handle the final capacity.

The run-of-mine coal will be delivered by skips to a 1000-ton capacity bin with two steel hoppers equipped with mechanical feeders delivering a maximum capacity of 340 net tons per hour to the Bradford coal breakers. The breakers will be 12 ft. in diameter and 17 ft. long, with screens having 1-in. and 1¼-in. mesh. The coal dropping through the 1-in. mesh is used for coking after it is washed, and the coal dropping through the 1¼ in. for boiler and producer use. The breaker refuse (rock, slate and sulphur balls) will go to a 110-ton capacity bin for loading into railroad cars.

The coal-washing machines will consist of 36 Campbell bumping tables, 12 ft. long and having a capacity of 2100 tons per day. All exposed gear and chain transmissions will be equipped with substantial guards, to comply with all requirements of the Pennsylvania Department of Labor and Industry. Each washed-coal concrete drainage and storage pit will have a capacity permitting a day's operation of the coal-washing machines; each pit after filling with washed coal will be allowed to drain 36 hours before reclaiming the coal for coking; this system of draining off the water from the washed coal will provide a product for charging ovens, averaging 7 per cent. moisture. The containing structure is of steel framing with concrete panels; it will be completed early next year.

The washery will be practically a duplicate as to design and will handle the same grade of coal as the Cambria Steel Co.'s washery and coke oven plant at the Franklin Steel Works. This plant near Johnstown, Penn., has been in successful operation since 1904, operating on the Miller "B" coal seam; for the year 1917 the following average results were secured.

	Ash, Per Cent.	Sulphur, Per Cent.
Raw crushed coal—unwashed	11.5	2.4
Washed coal—see note	7.3	1.3
Coke from washed coal	9.4	0.9

NOTE—Eight per cent. of refuse was washed from the raw crushed coal.

The coal used in the ovens at the Franklin plant consists of 70 per cent. washed low-volatile coal and 30 per cent. of finely crushed high volatile coal thoroughly mixed before charging.

For the year 1917 it cost (per ton of coking coal charged) 11.83c. for handling and washing the low volatile coal and 5.07c. for handling and crushing the high volatile coal. This cost per ton took care of the coal from its arrival in cars until it was delivered in the lorry bins—and it included labor, power and material and supplies for keeping the plant in good operating condition.

The Franklin washery was described and illustrated in *Coal Age* of July 20, 1912, in an article entitled "Byproduct Ovens, Johnstown, Penn."

In the United States the total bituminous coal production during 1917 was close to 542,000,000 tons and 90,000,000 tons of anthracite was marketed. The uses to which the bituminous coal were put have been estimated as follows: Stationary steam plants, 215,000,000 tons (40 per cent.) : railway locomotives, 190,000,000 tons (35 per cent.) ; households, 135,000,000 tons (25 per cent.) ; total, 540,000,000 tons. Of the 90,000,000 tons of anthracite 40 per cent. was consumed by locomotives and 60 per cent. mostly by domestic users. Reference to the figures given shows that 60 per cent. of the total production of bituminous coal in the United States during 1917 was applied to non-productive uses—35 per cent. for steam locomotives and 25 per cent. for domestic use.

Transportation Situation in Middle West

Reporting on the coal transportation situation in the Middle West, Hale Holden, regional director for the Railroad Administration, says: "There are 14 roads reporting to this office, although not all are included in the Central Western Region, and the loading shows 202,658 cars in August as compared with 202,549 for the month of June and 220,701 for the month of July, and as compared with 150,940 in August, 1917. The extraordinary loading in July, which was the greatest in the history in this territory, following the unusual heavy loading in June, resulted in a production greater than the market in this zone could absorb, and the Fuel Administration was obliged to cast about for ways and means of disposing of this surplus which led up to: (1) Zoning coal from western Kentucky out of Illinois, Indiana and Wisconsin, (2) agreeing to furnish a larger tonnage for the Northwest, and (3) opening the State of Michigan to Illinois coal, which it is thought will absorb 600,000 tons of the surplus.

"In view of the surplus of mine-run and screenings from the Central Illinois field, there has been no complaint in regard to car supply. The surplus of poorer grades of coal will disappear by the middle or latter part of September, but the roads in this territory are prepared to meet any demand that the car supply in sight can possibly make. Our biggest problem therefore is keeping up a full car supply."

Suggests Use of Highways for Coal Movement

Recourse should be had to highways wherever feasible to supplement the transportation of coal by rail, is the opinion of Cyrus Garnsey, assistant fuel administrator. In a letter to the Highways Transport Committee of the Council of National Defense, he says:

"We are also convinced that transportation resources can be greatly increased and larger tonnage movement of coal from wagon mines direct to consumers effected by applying all possible vehicles, horses and the necessary labor in line with national policies promulgated by you, and operating over suitable highways constantly maintained in efficient condition. For this reason we ask that you convey to our field organization our very real interest in this part of their work and assure them we desire to support their organization to the limit in their efforts to effect greater tonnage movement of coal over the highways from wagon mines to consumer.

"We suggest also that whenever conditions of roads, local legislation, lack of suitable equipment, and so forth, tend to impede the most effective and efficient movements, you will promptly bring these matters to our attention. To expedite the handling of these questions the Fuel Administration has committed them to its Mine Track Committee, composed of Frank G. Jones, Chairman, Robert L. Ireland and S. A. Taylor."

Power Situation Affects Fuel Supply

Extracts from the conclusions of Chester G. Gilbert and Joseph E. Pogue, with regard to the power situation, have been made public by the Smithsonian Institution. Messrs. Gilbert and Pogue, who are members of the Institution's mineral technology staff, declare that:

"The righting of the power situation requires (1) the establishment of a comprehensive system of electric transmission lines to be administered as a common-carrier system like the railways. (2) The provision of such a system will necessitate the coördinated growth of central power stations in coal fields and at water-power sites, and in doing so will open to business enterprise a tremendous field of opportunity hitherto closed off from entry, and thus lead to the balanced development of the two major energy resources, coal and water-power. (3) The principle of multiple production, recognized and incorporated in national policy, will supplement the additional service gained through the organized employment of the electrical principle; applied to the production of coal-generated electricity, and, through the medium of municipal public utility plants, to the distributive employment of coal, this principle will effectively correlate the recovery of the commodity and energy values, so as ultimately to effect a full saving of the former and an increased gain of the latter, thus permitting a further relative diminution of the amount of fuel calling for transportation in bulky form. The first two points reduce themselves to a single issue, which is purely a business proposition to be handled by a business organization; the third item is more intangible and it is a matter of policy, which, therefore, cannot be delegated or otherwise handled in objective fashion.

"Thus specific action in respect to establishing a common-carrier system adapted to the power needs of the country will not only go far toward solving the problem of transportation, but it will improve the fuel supply, correct the economic fallacy of drawing upon capital resources while neglectful of income, contribute to the recovery of the values now lost in the consumption of raw coal, lead to an adequate development of electrochemical activities, cut off a needless annual expendi-

ture running well beyond the billion dollar mark, and constitute a potent contribution in the direction of stimulating the upgrowth of a constructive economic policy of national scope attuned to the needs of modern industrial development. It is believed that these results would involve national economies, offsetting in large part the cost of the war."

Railroads Delay Shipments of Mine Timber

Considerable delay to mine props and mine timbers have resulted from the recent order from the Railroad Administration placing the movement of lumber on a permit basis. It was not the intention of the order to include mine props and timbers. Many of the railroads, however, have failed to differentiate between mine supplies and lumber which comes within the purview of the order. The telegraph is being used freely to secure the release of mine props which are sorely needed in many of the coal mining districts.

Fuel Administration Not Discouraging Recovery of Pyrites from Coal

The Fuel Administration took no action looking to the discouraging of the recovery of coal brasses from mines in the Middle West. When it was proposed to erect plants to treat these pyrites, the Fuel Administration simply insisted upon the precaution that the recovery of the coal brasses not be allowed to interfere importantly with the output of coal. The Fuel Administration suggested that the War Industries Board should allocate the production. It was feared that increases in the price of pyrites might make it more profitable to abandon the recovery of coal in favor of the other mineral. The Fuel Administration also suggested that the coal brasses extracted were to move in boxcars only.

Supplies for Mine Use Should Be Obtained from Local Sources

While every effort is being made to allow mine supplies to move without undue questioning, the Fuel Administration has found it necessary to stop all abnormal movements of supplies. Hay for use at a West Virginia mine, for example, was being shipped from Michigan. Another West Virginia company ordered a wagon from Orleans, N. Y. Officials here will insist that supplies be obtained from the nearest available source.

Coal Distributor's License Suspended

Distributors guilty of boosting the price of coal are being dealt with severely by the Fuel Administration. An example of the action being taken is the case of W. H. Blight, of Elmira, N. Y. He wrote prospective customers suggesting that he could secure coal for them if an additional 25c. per ton were forthcoming. The letter came into the possession of the Fuel Administration and Mr. Blight has been prohibited from transacting any coal business whatsoever for a period of sixty days.

D. D. Bush, of the Fuel Administration, is now engaged in working up the data, recently submitted by operators, on the steel requirements of the country's coal mines for the eighteen months prior to Jan. 1, 1920.

To Use Rejected Shell Steel for Chutes

That more chute steel may be provided, consideration is being given to a plan to work over rejected shell steel for that purpose. Shell steel is much too hard to make an ideal substitute for the regular chute steel, but as it can be made to do, it is probable that it will be gladly accepted. Fuel Administration officials are convinced that, with the present serious shortage of steel, it will be impossible to secure further supplies of chute steel at this time.

High Daily Average of Bituminous Miner

An example showing the possibilities of greater individual production is furnished by John Gulliver, of the Pleasant Hill mine of the Clearfield Bituminous Coal Corporation. In June, Gulliver loaded 270 tons, or a daily average of 10.41 tons of coal. In July, he loaded 288 tons, an average of 11.70 tons per day. In August, his output was 297 tons, a daily average of 11 tons. In August the daily average was 6.23 tons.

All records of the Pittsburgh district were broken last week when 130 out of the 134 blast furnaces in that area were in operation. The only four furnaces which were out of blast were being relined. This is quite in contrast with the situation early in February, when 38 furnaces were banked for want of coke.

Fuel Administration field men are reporting from many sections of the country greatly improved conditions as compared with this period of last year. They confidently predict that there will be no coal shortage this winter. Stocks already on hand insure a safe reserve for those periods in the winter when transportation tightens up.

Legal Department

EXISTENCE OF EMPLOYMENT RELATIONSHIP.—A teamster occasionally employed by a coal-mining company to make deliveries to customers, using his own team, cannot be said to have been an employee of the company while hauling a load of coal for his own account, so as to make the coal company liable to pay an award under the Indiana Workmen's Compensation Act on the man being killed, although it was understood that as soon as he had moved the particular load he would return and make a delivery for the company. (Indiana Appellate Court, Sugar Valley Coal Co. vs. Drake, 117 Northeastern Reporter, 937.)

LIABILITY FOR ACCIDENTS CAUSED BY SAGGING TROLLEY WIRES.—The Kentucky Court of Appeals has affirmed judgment in favor of a triprider injured while riding on an electric motor in a mine, due to sagging of the trolley wire when the wire broke at a nearby point. The injured man was declared to be entitled to recover on the theory that the breakage and sagging was caused by a worn condition of the wire which must have existed for some time and which would have been discovered before the accident had due care been exercised to maintain the wire in reasonably safe condition. The court approved the following statement of law given by the trial judge to the jury: It was the duty of the defendant coal company, if its wires carried a deadly or dangerous current of electricity, to use the utmost care and skill in the construction, management, and maintenance thereof, and it was the further duty to exercise and use the utmost care and skill to properly support the wires and to keep them in repair. (Key vs. West Kentucky Coal Co., 198 Southwestern Reporter, 724.)

THE LABOR SITUATION

General Labor Review

Events have crowded themselves into the last few days. The dissentients from the union in the northern anthracite field have declared themselves patriots and purged themselves of the crime of sedition by promising to await with due patience the ruling of Dr. Garfield in the matter of their wages. Then, again, Elbert H. Gary, chairman of the board of directors of the United States Steel Corporation, declared on Sept. 24 in favor of the eight-hour day. The men are to receive time and a half for overtime and double time for Sunday work. It is understood that the Lackawanna Steel Co., the Republic Iron and Steel Co., the Youngstown Sheet and Tube Co. and the Midvale Co. will follow suit. It appears likely therefore that the principle will be extended to the coal mines in which the steel corporations are largely interested.

Progress has been made also in the arrangements for the giving of badges for steady and meritorious service. It is highly important that some such action be taken promptly. Several companies have found that badges of their own devising have done excellent work, and doubtless far more efficient work would be done by the introduction of badges having national significance, especially if the presentation could be accompanied by the reading of a letter from the President such as he knows so well how to write.

It is much to be regretted that with the winter close at hand our good friends in the north are having so much trouble with labor. The difficulties seem to be arising everywhere except in Vancouver, where the shooting of the miner slacker Goodwin was expected to make trouble, but did not arouse much resentment in the miners. It appears, however, that all District No. 18 may go on strike to enforce a single-shift operation at one particular mine, despite all the promises made regarding legislation in favor of the single-shift operation of all mines. The Edmonton district has many men on strike and at the other end of the great Dominion, in Pictou County, Nova Scotia, there are all manner of strikes.

James Morgan is the chairman of the new union body which calls itself the "Anthracite Union" and has no affiliation with the United Mine Workers of America. It is said to have, so far, only 600 members. Talking about new unions, one has just been started by 80 petty officials of the Delaware, Lackawanna & Western R.R., Coal Department, the Lehigh Valley and the Lehigh & Wilkes-Barre Coal Co. They met in the Union hall at Wilkes-Barre and propose to band together the mine and firebosses who, because of their employing and discharging labor, can not become members of the United Mine Workers of America. They claim that they are discriminated against by reason of the fact that they have no union to enforce their needs and voice their demands. They receive straight salaries of $127 to $137 per month, but get no extra pay for overtime.

Upper Anthracite Region Not Pro-German

On Sept. 21 500 delegates from 70 local unions in District No. 1 (the northern anthracite field) met in convention in the Union Hall at Wilkes-Barre to protest by resolution against the general statement that they were tainted by pro-Germanism or by the evil spirit of the Industrial Workers of the World. Said they:

"We wish the world to know that we are not pro-Germans or I. W. W's or disgruntled obstructionists, but true and loyal American citizens and supporters of our great Government in anything it may undertake, as well as true and loyal members of the United Mine Workers and obedient to the wishes of its officials when said officials heed our demands and coöperate with the rank and file of the organization informing them by official communication of the progress made."

Then they add a promise in the words following to stand by Dr. Garfield as loyally as they do by the union if he will do what they desire:

"Whereas Dr. H. A. Garfield, United States Fuel Administrator, whom we honor and trust to give us justice when the facts are properly presented, has stated that we are entitled to an increase in wages and that he is now working on the amount to be granted as well as on the method in which to apply it, therefore be it resolved that we . . . pledge ourselves to be loyal to our great Government as we have been in the past, that we are bitterly opposed to any suspension of work pending the adjustment of our demands for an increase in wages and that we will do everything in our power to assist the Fuel Administration in the production of a maximum output of coal, and be it further resolved that we request the Fuel Administrator to alleviate the unrest in the anthracite region by naming a specified date when the increases will retract [to which the increases will retroact] and we believe that if this is done there will be no further trouble in the anthracite regions."

The 250 strikers at the Grassy Island shaft, the Grassy Island slope, the Olyphant and Eddy Creek collieries of the Hudson Coal Co. at a meeting held Sept. 17 at the Oliphant colliery voted to return to work. The men declare, however, that if an increase is not granted in ten days a second strike will be called.

The strike in the southern anthracite field is now completely at an end. It is computed that by their action the miners lost $200,000 in wages. The whole production of anthracite fell 11.3 per cent. Whereas it was 2,088,000 short tons the week before, it dropped to 1,847,000 short tons during the week of the strike. Fortunately the anthracite region only mines as much in a week as the bituminous region mines in a day. In other words, the bituminous output is six times the output of the anthracite region.

National Awards for Steady Work

The Department of Labor, as far back as May, 1917, began to consider the adoption of some form of insignia for the employees of plants engaged in filling Government contracts, the purpose being to show the public at large that the person wearing the insignia was doing his bit, at least in a degree, as was the man who was wearing the country's uniform.

The following rules and regulations concerning "The Issuance of War Industries Badges" have been drawn up by C. T. Clayton, Director of Training and Dilution, of the Department of Labor. The rules and regulations have been approved by practically all the employers of labor and by the employees themselves. All of the officers of the American Federation of Labor have approved these rules and regulations, but the national organization as a whole has not had an opportunity as yet to give its assent.

They have been presented to President Wilson for his approval and he also has been asked to write a pledge of loyalty which will be given to each candidate for the war-industries badge. The whole matter now awaits the approval of the President, upon receipt of which it will be given the widest publicity. The well-known New York artist Jo Davidson is engaged in designing the insignia.

Civilian war workers have long and generally felt that they were taking a vital part in the prosecution of the war

and were entitled to some recognition. Many of such workers, if they had their choice, would be at the front. For these reasons the Government has been considering the award of appropriate industrial insignia.

For the present it is proposed to limit the issuance of badges to civilian workers in those industries where a substantial proportion of the output is directly or indirectly required by the United States Government or by the allied governments and to such industries as are certified, by a competent Government agency, as essential. Care will be taken to exclude the concerns in any industry which are not actually working on Government or essential work. Wherever, from the mixed nature of the work or for any other reason a question shall arise as to whether the industry or the individual is entitled to the badge, the final decision shall rest with the Director of the Industrial Insignia Service.

The following service divisions have been established: Mining, war industries, shipbuilding (and ship repairing). Other divisions will be established as the need arises. A copy of his pledge of loyalty will be given on his enrollment to each candidate seeking the insignia, which the candidate will sign and the enrolling officer countersign. The pledge will also be placed upon the enrollment sheets; and at enrollment a description of the candidate's occupation, employment and nationality will be made out and a copy sent to the Director.

War workers shall be entitled to wear the War Industries Badge only if they work 100 per cent. of the established working hours in each month; less such absence as is involved in a customary vacation, or because of sickness or some other unavoidable cause. Candidates will be invested with the base of the badge, which contains the candidate's official number. At the end of four months' service each candidate properly adjudged to have complied with the standards will be awarded the primary disk. Upon the expiration of each further period of four months' service a new disk, indicating the additional service, will be substituted for the original disk, which forms the center of the badge. When the badge is introduced in any plant such workers as satisfy the administrative officers that they have complied with the rules for four months or more shall be immediately awarded the full badge.

For local administration there will be an enrolling committee of not less than three at each plant. One of the committee will be a person having authority in the corporation. He will represent the employer. The rest of the committee will be elected by the employees, one for each shop or department. The chairman of the committee will be nominated by the members, subject to the approval and appointment of the Secretary of Labor.

Such committee shall have the following powers and duties:

a. To enroll candidates for the War Industries Badge.

b. To ascertain the cause of absences or shortened working hours of any war worker who fails to work the prescribed periods, or to produce either in quality or quantity his fair proportion of output.

c. To decide to whom badges and indicia of service shall be awarded.

The names of candidates whom the committee think worthy of the badge or succeeding indicia shall be submitted to the employer before public announcement, giving him an opportunity to object to any name and to discuss the matter with the committee. In case of disagreement the matter will be referred to the Director for final settlement, a written statement of facts being supplied him as a basis for his decision.

Rules To Be Observed in Distributing Badges

a. Upon enrolling, each candidate will be entitled to the beginners' badge, which shall consist of the pin and bar foundation of the badge, without the indicative medallion, but bearing upon it the serial number assigned the possessor for use during the war; the badge and all indicia to become his property thereafter if not forfeited for cause before the close of hostilities (see rule d).

b. Upon enrolling, each candidate will also receive a card containing his name, address and other identifying information and a copy of the pledge, such card to be signed by the candidate and countersigned by the enrolling officer. Each candidate will be required to furnish a photograph measuring approximately 1½ x 1 in. and mounted upon the card. At the termination of each month's service, the card shall be presented to the committee for endorsement.

c. A war worker permanently disabled in service will receive a special disk, to be placed upon his badge, indicating that fact; such disk being public acknowledgment of the worker's patriotic service and honors.

d. Whenever a war worker desires to leave his employment for any cause, he shall surrender his badge to the committee. If he satisfies that committee that he has taken up war work elsewhere, the committee will grant him a transfer card, directed to the local committee at the new establishment; and upon presentation to that committee they will advise the first committee, which will redeliver the badge to the war worker through the committee at the new establishment. If the war worker has no new job in view, the committee at the establishment he is leaving will give him a transfer card directed to the nearest office of the United States Employment Service. Such card will entitle the war worker to especial assistance in securing other employment in war work. Upon placing the worker, the examiner-in-charge of the Employment Service office will notify the committee, or the war worker may apply through the committee at the new establishment, which shall notify the committee at the original establishment; and if the new employment has been taken up without unreasonable delay, in the judgment of the committee, transfer of the surrendered badge shall be made and due notice sent the Director.

KEEP IT BURNING

e. The War Industries Badge will not be awarded to boys between the ages of 16 and 20 years, in localities where the Boys' Working Reserve training system is in operation. In

establishments having members of that organization, the committee will award to boys within the prescribed ages the Boys' Working Reserve Badge instead of the War Industries Badge, and such boys will be expected to become members of the Boys' Working Reserve and conform to the rules of the reserve regarding industrial education, which will be a part of the qualifications for award of their badge.

When such boys have earned the Boys' Working Reserve Badge they may on attaining the proper age be awarded the War Industries Badge in addition to the Boys' Working Reserve Badge, and that badge shall be given with indicia which will indicate the full period of service performed, including the service while earning the Boys' Working Reserve Badge.

f. The Government does not obligate itself to replace a lost badge or medallion. Should a member lose these, he can become a candidate for a badge only as a new worker. Any persons who may find a lost badge are requested to return it to the nearest local committee, which will forward it to the Director to be returned through his local committee to the person to whom it was first awarded. The badge is the property of the Government, and not for sale at any price; nor can it be given to any one except upon an award duly made by a regularly constituted committee, or upon a special award by the Director upon sufficient evidence justifying such action. The badge will remain until the close of the war the property of the Government, protected by the sanctions regarding unlawful conversion of Government property. If declared by a local committee to be forfeited, and the sentence is not reversed by the Director, the holder must return his badge to the committee for cancellation. If a war worker quits his job he shall return the badge to the local committee. (See rule d.) The employer is requested to assist the committee by taking up badges when he pays off war workers who are leaving his employment.

g. Appeal on any matter connected with badges may be made by any party to the Director.

RULES REGARDING THE CONFERRING OF BADGES

Badges should, whenever possible, be conferred upon candidates in groups or classes, with simple but impressive ceremonies. The members of the enrolling committee, headed by their chairman as an accredited representative of the President of the United States, should be present; the rehearsing of the pledge of service, the hoisting of the flag and delivery of a short address by some noted citizen with the formal conferring of the badges by a Government official or officer of rank should be elements of the program. The badge represents the honor and dignity of patriotic service, recognized by the Government of the United States. It is an American Legion of Honor; and no lack of respect should be shown in conferring it upon those who may earn the right to wear it.

Large Outputs of Patriotic Miners

We have received information regarding several big records of earnings and coal production. Some of these have been published, but they will bear collecting. Joseph Malachick drew $158.34 for two weeks' work at the Adelaide plant of the H. C. Frick Coke Co. His pay for four weeks was $300.96.

Harry Pyle, a miner employed by the MacGregor Coal Co. at the No. 1 Bando mine near Rockwood, Somerset County, earned $516.10 from July 15 to Aug. 16. As this period includes 26 working days, his earnings averaged $19.85 per day. The work for which he received the pay stated included the mining by hand of 410.26 long tons of entry coal, the lifting of 34 yd. of bottom at $2 per yard, the lifting of 10 yd. of bottom at $1 per yard and the working of two hours at 64½c. per hour. The coal mined by Pyle per day averaged 15.78 long tons.

The seam in which he worked was only about 4 ft. thick. He started the last half of August by mining 22, 21 and 18 tons in three consecutive days. Pyle is about 38 years old, and weighs about 165 lb. He is 5 ft. 10 in. in height. The mining rate figures $1.06 5|10 per ton.

The illustration herewith shows William Bumpus, a colored man, who is engaged by the Carbon Fuel Co. to load coal at its North Carbon mine, Decota, Kanawha County, West Virginia. In July he loaded 650 tons of coal and handled 70 tons of slate, yet he laid off three working days in that month so that he could work in his war garden. The coal he works in is the Eagle seam, which averages at North Carbon about 4½ ft. in thickness. Bumpus has always been a consistently high coal loader, but in July he distanced his own record. He is ready to defend that record and surpass it if Uncle Sam will furnish the necessary railroad cars.

WILLIAM BUMPUS LOADED 720 TONS IN A MONTH

Moundsville, W. Va., announces that one miner in that region, Charles Fogel by name, earned $169.89 for 11 days' work. One day in that period Fogel celebrated by loading 30 tons 17 hundredweight. He made $18.20 during that eight hours of work. The rate must therefore have been 59c. a ton, and the 11 days' record, 287 tons and 19 hundredweight or an average of 26.18 tons per day.

This beats even the records of Ed Blagg and Joe Swagda as recorded on July 6, 1918, on page 29 of *Coal Age*. It must be remembered, however, that Blagg was working in an entry and perhaps his coal was thinner, for it was only 3 ft. 8 in. thick. It would appear that the Bumpus record closely parallels that made by Fogel, if it is assumed that Bumpus worked 24 days in July and if his slate is figured as coal. His tonnage then would be 26.25 tons per day.

Other records are coming in which prove the industry and patriotism of our coal miners. John Mullins, a miner at Hemphill, Penn., who works for the Solvay Collieries Co., dug and loaded 691 tons of coal between Aug. 15 and Sept. 14, a wonderful record—25.59 tons a day on the assumption that he worked 27 days, the number of week days occurring in that period of time. The rate paid for mining appears to have been 65c. a ton, for the wage was $449.15.

Leave the Mines To Get Drafted

The operators of Illinois complain that the exemption of miners and other mine workers does not exempt. The younger men would rather fight than dig coal, and they find that while there is no direct route from the mine to the national service, indirect routes are not yet tightly closed. A man can always leave the mine and get employment at a factory making nonessentials, and from such a plant there is a wide-open door to the army and navy, which he accordingly enters forthwith by enlistment or draft. Many of the men thus leaving are drivers, and as a driver or motor runner will haul from 30 to 300 tons a day his absence causes more loss of tonnage than is caused by the absence of a coal digger.

The Flag at Your Tipple Means Nothing If You Have Not Its Service in Your Heart—Buy Liberty Bonds

Pledges should be made in bunches. Do not make a pledge to buy Liberty Bonds without pledging yourself: (1) To earn by steady work and (2) to save by a frugal life enough money to pay for the bonds in a few months. He who works steadily makes materials for war, and he who saves his money saves material and labor which can be applied to the support of the fighting forces.

EDITORIALS

When Your Neighbor Is Angry

WHEN YOUR neighbor is angry it is his troubles and not he who speaks. Now more than at any time is the time for the operator, superintendent or foreman to keep this piece of plain fact, as a motto before his eyes, lest he flare up and make trouble with his employees that he will later regret. There is usually something back of an exhibition of grouchiness. In every instance let us try to find out what that something is, so that we can remove the trouble or at least assure our aggrieved neighbor that he does not help matters by his violent expression of anger.

It will help us, also, if when we meet with anger we forget the person who manifests it and fix our attention on the cause of the worry or trouble, on something impersonal. Nothing is more soothing than a keen diagnosis. It soothes us to regard the irascible man as a "patient" in the fell clutches of a disease or a circumstance. It diverts one's attention from his reactions of the "patient" and concentrates the mind on underlying causes.

Many a foreman appears to have an extremely irritable temperament. His language to the mine workers under his care is not warranted to make them friendly to him or to the companies employing him. So long as we load him with responsibilities and duties that one man cannot fill it will serve but little to counsel him to be more prudent and considerate. His troubles, and not himself, will continue to do his talking.

You surprise him at home with his family and find he is a pleasant, mild mannered man, with a devoted wife and happy children; but at the desk of his mine shanty he is like a caged lion. Relieve him of some of his duties, badger him a little less at the daily interview and give him a little wholesome advice of a sedative character and see him become bland and encouraging again.

The first duty of a superintendent is not to scold but to hearten a foreman, to give him a cheerful outlook on affairs that will help him to do his work without worry. Work without worry and work without fatigue should always be our aim. We almost never should pay a man to worry, and we should but rarely ask for work that would make an accustomed worker fatigued. A willing, ready worker is what we all want. What are we doing to make our workers both ready and willing? It can't be done by overexaction, because that inevitably produces worry, excitement, feverish action and ill-considered behavior. It can only be done by loading each man to capacity, forbidding him to accept any further duties, and by providing him with a good example of courteous consideration. A man who receives courtesies in the main office is likely to show courtesies in the mine office. An untroubled man is like a well-laid fish line, not likely to get snarled; but, like the line, when once he is disarranged, endless trouble is in store.

Why We Pay More for Cleaned Coal

THERE are not wanting people who claim that there should be no extra price conceded for coal cleaned by picking devices or passed over a picking table. They argue that coal should be cleaned at the face, and if it needs more cleaning it has not been properly cleaned by the miner. It is true that the miner should clean the coal before loading it into the car and should exercise judgment to keep dirt out of the coal, but when he has done all that is within reason he cannot produce a coal comparable with that cleaned at the tipple.

It must always be remembered that picking coal, even bituminous coal, is, for several reasons, an expensive operation—it takes labor, machinery and power, and also buildings to house the operation; moreover, it also removes a large part of the material for which the operator has already undertaken to pay, for the weight is taken before the waste material is picked out.

Of course, the operator can often use a portion of that waste. Little of it should be entirely incombustible; some of it will be "sulphur," or pyrites, which as fuel has a low thermal value; some of it is a coal high in ash but burnable. But whatever it is, its value is not equal to that of the coal which is to go to market, and the operator who takes it out needs to be recompensed for its loss, whole or partial, as well as for the labor involved in the systematic losing of it.

It has been contended that the operator who cleans his coal admits tacitly that he has neglected to keep his miners in line, and has permitted them to load dirt. All that can be said about this accusation is that, if this is true, in doing so he has wronged himself; for he must, in cleaning, throw away or use the rubbish his workingmen have delivered to him and do it all at his own loss of material and labor. No operator who begins to run a picking table relaxes in his efforts to keep the dirt in the mine. He is apt rather to be more active than before, as he keeps a closer record of his losses.

The extra payment made, therefore, for coal passed over a picking table or picking device is a payment that is earned. It is a return for money expended and for values actually lost. To fail to pay it would be to perpetrate an injustice. Like all injustices, it hurts two classes; in this case the operator and the public, for when the profit in cleaning coal is lost it will not be cleaned and the public will suffer accordingly.

"Do Your Bit"—What Do You Mean, "Bit"?

SINCE we entered the war the expression "Do your bit" has been freely used in America. Some people have remarked that it is a highly inadequate expression, and they wonder how it came to be so current in Great Britain, when the "bit" everyone was doing, whether rich or poor, was so amazingly large and entailed such a degree of self-sacrifice.

It is, however, but a small bit or share of the whole magnificent national endeavor that any of us can ever do. Work and struggle as we may, the action of the individual must always be dwarfed by the greatness of the effort of a hundred million of our people leagued, moreover, as they are with the legions of our Allies. Yet it is important that each of us do our "bit," our full share, and make our proper contribution to the whole result. We must all give to the great endeavor either in Liberty Loans or in taxes. Each can only do a bit; the more need therefore that each one does that bit that the whole aggregate effort may be worthy.

There are about 40 million wage earners in the United States, and they are asked to tackle a loan of six billions of dollars. The bit of the average wage earner is therefore $150. Remembering how greatly the receivers of large incomes are crippled in their purchasing power by unequal taxation, we cannot expect them to shoulder as much of the burden as they otherwise undoubtedly would. The amount of $150, therefore, does represent closely the bit or share demanded of the least of us, and those who make a good earning should put up far more.

Do not believe that any inherent honor exists in being born or admitted by naturalization into the citizenry of a great country with magnificent traditions. Those who were born to America could not help themselves; those who entered our country were accepted without any careful inquiry. The distinction is not in our citizenship, but in our patriotism. Our honor rests solely in the contribution we make to those splendid ideals and that glorious history that is America.

It is our "bit" that counts, that makes our citizenship an honor and not a disgrace. He who lives among a people born to honor and world service is not ennobled by that association, but is rather disgraced, if he cannot hold his head erect and fearless in that company.

Large then as the birthright we have received must ever be the service we render. Our "bit" must be big that we may rightly appropriate, each one to himself, the virtues of his ancestors and foster ancestors. It is useless for Æneas to proclaim that he has descended from the gods if he bemean himself like a swineherd. This is the hour of all hours at which we can show whether we belong or do not belong to our glorious past, if it is ours or another's—this America, this tradition. The Liberty Loan is only one of the many opportunities now offered us whereby we can prove the spirit and mettle of our souls.

The Question of Water-Power Development

FROM time to time in the past, but particularly since the introduction of proposed legislation into Congress for the provision of more power where needed, the question of developing the water-power of the land has been agitated. Many there are who now, through the press or from the stump, loudly proclaim that available water-powers, wherever located, should at once be developed, that the neglect of this source of energy is costing this country one of its irreplaceable natural resources, which should by all means be conserved.

Now, in a measure, all of this is doubtless true—but the perspective with which it is viewed is awry.

Great engineering feats are undertaken for one of two reasons—to tickle the vanity of some individual or group of individuals, or because they will pay. The pyramids, palaces, hanging gardens, temples, etc., of ancient times were examples of the former; the railroads, the bridges, the gigantic ocean liners of modern times are examples of the latter. Ask any banker to find capital wherewith to finance any industrial project and the question will be immediately asked, How much will it earn?

The present is an abnormal time wherein normal economic conditions are in many respects "sadly out of joint." It is inevitable, however, that a time will come when ordinary conditions will again prevail. At present the task before the American people is to at once and forever absolutely crush Prussian militarism. Whatever means may be necessary to this end must be employed, and this with as much speed and dispatch as possible. More power is needed for war manufacturing, and the quick way to get it is with steam-power plants.

So far as the wanton squandering of the nation's coal is concerned, about which so much is being spoken and written, all that can be said is that coal is being used for the generation of power purely and simply because it is the cheapest source of energy. It is true that water costs nothing, but the equipment necessary for its utilization costs much. Coal-power has held supremacy over water-power in the past and will continue to do so until economic conditions dictate otherwise.

To sum up, regardless of how fervently the editors of popular magazines or vivid "yellow" sheets may entreat, how eloquently senators and representatives may thunder, how viciously soap-box orators may rant, the water-power of the land now running to waste will be harnessed and made to generate needed energy just as soon as legal restrictions will permit and such development will pay a reasonable return on the money invested. It will not be done before.

No Covenanted Peace with Germany

AMERICA, unless we repudiate civilization and abandon humanity and put a premium on savagery and brutality, can make no covenanted peace, no peace by agreement or negotiation with Germany. It would be a covenant with hell, a partnership with infamy.

Nor would such a peace secure peace, except so long as it suited Germany. We can judge the future only by the past, and to Germany sacred treaties are scraps of paper only. Germany's whole history is a record of national treachery, national bad faith, national dishonor, national murder, and national infamy.

Of the old men and children murdered, of the women and girls ravished, of the noncombatants taken from their homes and deported to work for their conquerors, of the merchant ships sunk and passengers and crews murdered, of the hospital ships sunk, the hospitals and unfortified cities bombed, of the mutilation and murder by crucifixion and otherwise of wounded and captured soldiers—of all this beastliness there is plenty of evidence, evidence that no one can disbelieve.

The best answer to German peace propaganda is sinking more U-boats, sending more men to France, speeding up our work along every line, and a heavy subscription to the Fourth Liberty Loan. Peace must mean the triumph of right and justice, the defeat of Germanism, not a truce with it, not a compromise with it.

DISCUSSION BY READERS

Mine Rescue Work

Letter No. 3—I have been deeply touched by the reading of the two letters that have appeared recently in *Coal Age* (July 6, p. 32, and Aug. 8, p. 283), describing rescue work in mines. The accounts given recall to my mind the distressed faces of miners who were brought to the surface, after weeks of suffering in the dark chambers of the Courrieres mine, in France, following the terrific explosion of Mar. 10, 1906, when 1200 miners were lost in that death-dealing blast.

We did not have, at that time, the efficient breathing apparatus with which to enter the mine, and there came to our aid hundreds of Westphalian miners who had been well trained in the use of such apparatus in rescue work. Thanks to their help, the mine was entered and the work of rescue commenced.

As time went on and days passed without the rescue of many whose lives we had hoped would be saved, that hope was fast dying in our hearts. The company was claiming that all the men remaining in the mine were killed and argued that, to save the property from further damage by the fire burning in the mine, the workings should be flooded.

Remarkable Rescue of Entombed Miners

Just then, one committeeman who had fought this proposition from the start, claiming that there were miners still alive below, went down again and entered a certain air-course where he came upon the dead bodies of men that he was sure were not there on his previous visit. His report of this caused the rescuers to make renewed efforts, with the result that 20 days after the explosion, 13 men were brought to the surface alive.

The men rescued were in a pitiable condition, having lived on dead horseflesh for many days. They had found shelter in a stable where the afterdamp did not penetrate. One can imagine what joy the rescue of those entombed men brought to many waiting hearts. Again, five days later, Apr. 4, another miner, named Berton, was rescued. In reply to our inquiry asking how long he thought he had been in the mine, he said "eight days." He little dreamed that he had been down in those dark chambers 25 days.

The fact that such rescues have been made should prove conclusively that the deadly gases of the afterdamp often do not penetrate the entire workings of a mine, and there is always a possibility that trained men, with efficient breathing apparatus, will be able to reach men who still live, having barricaded themselves in a chamber to escape the fatal atmosphere filling the passageways of the mine. In the Courrieres disaster men were found in such positions as to indicate that death overtook them instantly, the afterdamp giving them no opportunity to escape, but this is not always the case.

Let us remember that the past good record of a mine for safety must not be relied upon to that extent that men cease to watch and use every precaution to prevent coming disaster. The Courrieres mine had the reputation of being a safe mine, but greater precaution should have been used as it was known that danger was near, owing to a big fire in progress, in an adjoining seam of coal. The day of the disaster a few miners refused to enter the mine, my cousin among the number, fearing the danger they had to face.

Let me suggest, in closing, that more attention should be given to planning the ventilation of a mine with a view to assisting, in times of danger, in the work of rescue. Also, let every effort be made to improve the types of breathing apparatus now in use. The Gibbs apparatus, developed by the Bureau of Mines, is a step in this direction.

GASTON F. LIBIEZ,
Peru, Ill. Mine Examiner.

Perplexities of Mine Foremen

Letter No. 1—It was with much amusement and a good deal of appreciation that I read the editorial entitled "Let the Operator Get On the Job," *Coal Age*, July 25, p. 185, but dealing with the perplexities of mine foremen. If there is an employee around the mines who comes in for more trouble, and who carries, or miscarries, greater responsibilities than anyone else in the mine, it is the mine foreman.

The description given in the editorial is true, every word of it. In the position he occupies as an officer charged with the carrying out of the mine laws, and as an official of the company charged with the management of the mine, the mine foreman is truly a cross between a "safety engineer" and a "mine manager." In the present crisis, the title "Mine Foreman" might be defined as applying to that official who is responsible for *"a maximum of production for humanity's sake."*

Early on the job, in the morning, his troubles begin. The machine runners have not cut the coal in many places, which must remain idle for the day, as the loaders in those places are going home. The outlook for the day's run is dark, but the mine foreman, though an ordinary human being, must grin and bear it, although he may give expression to his feelings by a few cuss-words, occasionally.

Eventually, however, if the man is worth while he masters the situation as best he can and the hoisting of coal begins. He then turns his attention to the supplies of timber and tracking ordered by the men, on learning that these supplies are short. His requisition sent to the office some time since has not been filled and the men must wait; but the foreman must keep the coal running. His problem is to hold the men in their places and be responsible for their safety, until the needed supplies can be had.

A good mine foreman knows that to produce coal many things are needed; it may be better tools, powder,

facilities for haulage are urged; a motor to take the place of several mules in a certain section of the mine, and other changes to enable him to put the required tonnage on the tipple.

Many excuses and promises are offered the mine foreman by the management in response to these suggestions, but the desired equipment is not forthcoming. Too often it happens that a wiser head than his has changed his requisition, in the office; and an inferior quality of material, or a different brand of supplies than that indicated are furnished, because of its cheapness. It is false economy to send material into the mine, supposing that the man who must use that material can get the same results, and assuming that he does not know the best brand and understand his own needs better than the man in the office.

Another source of worry for the harassed mine foreman arises when the superintendent is called to account for failure in tonnage or an increased expense sheet, or other matters of a similar nature, and passes it on to his man, "Friday," whom we all recognize as our friend, the mine foreman. The big chief may not get to the mines more than once a year, and his coming is the occasion for many annoying requests made to the superintendent, but which, eventually, fall as a burden on the shoulders of the foreman in the mine.

Lest it should be thought that I consider all mine foremen good and competent to fill the office they hold, let me say that I have observed many incompetent men in this position, both in anthracite and bituminous mines. A good foreman never acts as if he owned the mine, while a less efficient man will show his incompetency by the abusive manner in which he conducts himself, and the heedless way in which he rushes here and there about the mine, but accomplishes little. The incompetent man impresses you with the fact that he is *boss*, which is something seldom observed in a good foreman, whom the miners come to respect, knowing that what he says goes.

Mistaken Conception of Authority

Well do I remember a visit to a mine in the southern anthracite region, where I went, in company with a party of bituminous operators, to inspect a certain large mine. The superintendent of the mine was with us, while the foreman piloted use through the workings. If ever a foreman showed his incompetency, that man did, by his manner and his many attempts to display his smartness, while every instruction given to his men was accompanied by an oath.

The impression on the minds of the visitors was that the production of coal in that mine would be greatly increased by putting another foreman in charge. In my opinion, however, Murphy was only the victim of improper training. Perhaps, he never had a chance to make a good mine foreman of himself. He had never been shown the errors of his ways, or reasoned with by a superior in office; but had grown up as a weed.

Let us study the mine foremen who are under us, strive to lighten their load and make them better and more efficient men. They are really the mainsprings of our mines, being in daily and intimate contact with the men who mine and load the coal.

Let us realize that the lot of the foreman is a hard one and be ready to recognize the man who has an ambition to rise. Many a foreman has the natural ability to make a good superintendent; perhaps, even surpassing the qualities of the man who is his superior in office. No man can progress today, unless he is a man of the hour and continues to grow each day.

Philadelphia, Penn. OBSERVER.

The Miner and His Pleasure

Letter No. 4—Since our country entered the war, the coal miner has had little time or inclination to think of pleasure. The scarcity of coal, in addition to the patriotic feeling of the average miner whose chief desire is to serve his country at this time and stand behind the boy "over there," has deprived him of even the thought of pleasure.

In almost every window of the miners' homes throughout the anthracite field hangs a National Service Flag, having from one to four stars, in token of the number of boys who have gone out to answer their country's call. The abiding thought in every mind is "duty today, pleasure tomorrow."

Sometimes I think too much is expected of the coal miner. The many complaints registered against this class of workers leads the public to hold them entirely responsible for meeting the utmost demand for coal and guaranteeing the winter's supply. The charges that miners are frequenting the saloons and that liquor is keeping them from their work in the mines fail of justice to the average miner.

Saloons in Mining Camps Not Thriving

In most mining camps, today, the saloons are not thriving; many have been obliged to close their doors and their keepers have gone to work in the mines. It is a common thing to see, in the daily press, the charge of drunkenness, and the writer's invariable claim that this is the cause of the shortage of anthracite.

If the statement of Mr. Buttons, chief of the Department of Mines of Pennsylvania, in addressing the retail coal dealers, in Harrisburg, some time ago, is true, that "drunkenness among miners is the sole cause of 20 per cent. of the shortage of anthracite," why does the Government permit this evil to go on?

In my opinion, one of the chief drawbacks to coal production, in the anthracite region, is the low wages paid to the miners, as compared with the attractive wages offered in other lines of work. Scores of miners are leaving the mines every day to take up other work. While some mine workers are making good wages, the average is below that of workers in other industries.

Great Need of Stabilizing Wages

Wages and cost of living should go hand in hand. The one should form the basis for computing the other. It would be well for the Bureau of Labor to continue its investigations of living conditions in the coal regions, and either make an adjustment of wages or control the rising prices of living necessities. If the cost of the latter were stabilized wages could also be stabilized, and such an achievement would be a blessing to all industrial workers.

The Government has stabilized the prices of wheat. sugar and some other things, but the movement should be extended further. If the Food Administration, through its methods and influence, can exert a pressure

to restrain speculators and profiteers from boosting the prices of a few essentials it should be possible to control all necessities of living, in a like manner.

Some time ago, I saw an item in a newspaper quoting President Wilson as stating that "profiteering is yet a rampant evil." The statement should be an incentive to more energetic and effective efforts in restraint of such practice. Certainly, the adjustment of wages and the cost of living should be of vital concern to the Government, in the present crisis, with a view of holding the mine worker in his place in the mine.

Attitude of the Miner Toward the War

Since the "Work or Fight" slogan was created and became a national policy, the attitude of the average miner is expressed in the words, "I will work where they will pay me the most wages, or I will fight with the boys in France." Coal miners appreciate their importance as workers in an essential industry, but they do not like the idea of being entirely barred from doing their share of fighting; they are opposed to class exemption. They have proved themselves fighters and can be excused for their desire to be made part of the American army that will some day *tread the streets of Berlin.*

The coal miners are true to this government; and that fact is the reason why the anthracite fields today are short from 35,000 to 40,000 men. Notwithstanding this shortage, the production of anthracite has never been greater than in the past year. Any miner, foreman, superintendent or operator who is not doing his level best to increase the output of coal, today, is watched as a dangerous man—a public enemy.

Before closing, I wish to ask a question in regard to the granting of vacations in war time. From mine official to miner, everybody is assumed to give superlative service, doing the best possible. In peace time, I believe a vacation should be allowed every working man under the sun if the man is worked to his capacity. I believe that the human body is like a machine and needs time to rest for the repair of the system. The rest accorded to mine officials, by all large coal companies in the Wyoming Valley, is for the most part a rest for the brain. Is that needed any more than rest for the muscles of the body of a mine worker?

Some time ago, a young man, working in the Wilkes-Barre Court House, was granted a vacation of ten days. He went into the mine for his vacation and loaded 200 tons of coal, showing his patriotism. Men should be honest with themselves. War-time vacations should be for the upbuilding of brain and muscle and not simply for jollification and pleasure. President Wilson has said, "we must not think of pleasure, until after the war when we will all have a big time." MINER.

Kingston, Penn.

Loading Coal at the Face

Letter No. 5—Referring to the record of Ed. Blagg, as given in *Coal Age,* July 6, p. 29, where it is stated that he loaded an average of 23 tons of coal a day of 8 hours, during the month of May, when working in No. 1 mine of the Buckeye Coal & Railway Co., at San Toy, Ohio, let me say that, although this is a remarkable achievement, we have no right to doubt the truth of the statement. I have heard some men remark that it could not be done, but they are men who fail to recognize that conditions are not everywhere the same as those under which they are working.

Here in Kentucky, I can say with truth, it would be impossible to make the same record. In this field, the miner is required to work under roof conditions that are often bad, besides being obliged to pick out the bone and sulphur from his coal when loading it into the car. It is my belief that, when stating facts or describing work performed in the mine, we often fail to give the particular conditions that made such possible. Many who read the account do not realize the great difference in the conditions in many mines. Hardly any two coal fields are alike, and the work of loading coal depends very largely on these conditions.

In mines where I have worked in Williamson and Franklin Counties, in Illinois, there is about 7 ft. of good clean marketable coal, overlaid with a good roof. Compare the work of loading coal under these conditions, with that in mines in Indiana in the low-coal region, or in the low coal of the Hazard, Harlan, or Pineville districts of Kentucky, or in some of the mines on Coal River, in West Virginia, or the low coal in the New River district. In any of the districts just mentioned, a miner could not be expected to load as much coal as when working in a thicker seam and under more favorable conditions.

There are, however, some disadvantages in loading coal in a high seam. In most cases the height of the car, in such seams, makes it difficult to load the coal with the same speed. Also, the timbering frequently requires more time and the cars being heavier are not as easily handled as the smaller cars in low seams. But these difficulties do not restrict the loading of a large tonnage to the same extent as does the handling of a draw-slate, which is so common in the working of a low seam of coal. In most mines, the miner must do his own timbering and in many cases, lay his own track. The tonnage a man can load then cannot be compared with what he will load when most or all of this work is done for him, as in many mines in Illinois.

In one mine, at least, in Hopkins County, Ky., the company employs shotfirers, who drill and shoot the coal, and the loader has nothing to do but to load it into the cars. When a loader has loaded all the coal in one place, he goes to another where there is loose coal ready to be loaded. He will generally try to find a place where the coal is handy to the track so that he will not have far to throw it into the car.

Working Conditions Determine a Man's Tonnage

It is readily seen that a comparison of the tonnage per man, under these varying conditions, cannot be made with justice to all. In order for a man to load a big tonnage in a day, he must have his place cut regularly, the empties must be there for him to load, and he cannot be expected to do much timbering or tracklaying. In addition, he must have a good light and good air. In this field, all shots are fired at quitting time, which gives the miner a great advantage as compared with places where the shots are fired at any hour of the day.

Since reading the poster page, in *Coal Age,* giving the record to which I have referred, I have tried to keep tab on five miners who are average workers. I find that these men spend, on the average, one hour in drilling

and charging the hole and about 15 minutes in timbering their places, which leaves 6 hours and 45 minutes for loading coal, in a day of 8 hours.

About a third of this time, however, is wasted in waiting for empties, which leaves only about four hours and a half for loading. Watching these men closely, I found that it took about twenty minutes for them to push a car into the room and load it. The cars held a ton and a half of coal and, at this rate, they could load about twenty tons each a day if they kept at work.

This is not claimed to represent the average tonnage per man, in this field. In my opinion, it could be much increased if the loaders were given half a chance; but, in many cases, the fault lies with the operator who has not provided the equipment necessary to keep the coal moving. When the drivers do their best the mule power employed is inadequate to haul out of the mines all the coal the miners can load. The trouble is not in loading the coal, but in putting it on the tipple.

Cleaton, Ky. OSTEL BULLOCK.

Use and Location of Booster Fans

Letter No. 2—I was much interested in the inquiry of "Mine Superintendent," *Coal Age*, Aug. 8, p. 287, in regard to the proper location for a booster fan when changing the circulation, as proposed in the second figure on the same page. It is not stated whether there are any entries working outby from the 9- and 10-E and W entries off the 9- and 10-N entries, shown in his sketch.

In replying to this inquiry, I will assume, first, that there are other entries working outby from those shown in the plan submitted. In that case, the air in the ninth and tenth cross-entries could be increased by placing regulators in the outby section or sections, provided the circulation in those sections is in excess of what is needed.

The building of the overcasts at the mouth of the 9-E entry, and splitting the main air current at this point so as to provide separate circulations for these east and west entries is a good suggestion, as it will increase the quantity of air in circulation, since the air in each split will then have only half the distance to travel. My suggestion of placing regulators in the outby sections would, of course, increase the water gage and reduce the total quantity of air circulating in the mine; and it is probable this would offset the good effect of building the overcasts and splitting the air at the ninth and tenth entries, all of which must be carefully considered. Such being the case, the only thing remaining to be done is to increase the power producing the circulation or to install a booster fan.

Assuming that the 9- and 10-E and W entries are equally developed and the same number of men are employed in each section, the proper location of the booster would appear to be at the intake airway, near the overcast and before reaching the point of split. Since the return airway in this mine is also the haulage road, the fan cannot be located on that entry. By locating it on the intake airway near the overcast, it will have the effect of increasing the volume of air in both the east and west sections, without placing regulators in the outby sections, as suggested previously.

It is my opinion that a booster fan will work equally well whether forcing or exhausting the air. Its location on the intake or the return airway must be governed by the conditions. In this instance, the location on the intake is determined by the fact that the haulage is performed on the return airway. I am assuming, now, that the stoppings inby and outby from the booster are in good condition, as otherwise the air would leak through the stoppings, and the current inby from the fan would not all reach the working face. The result would be that the leakage outby from the fan would cause that air to pass through the fan again and again. The booster would thus do little more than churn the air.

Referring to the statement of the inquirer that he is "inclined to place the booster in the return current, either on the 10-E or 10-W entry," I fail to see how he would get any benefit from such an installation, even admitting that the fan would work better as an exhaust than as a blower, unless one of these sections is working more men than the other and requires more air. Where both sections are working the same number of men and need the same quantity of air in circulation, the location of a booster in one of them would not give that result.

In my opinion, the only way in which the booster, in this case, can be used as an exhaust fan would be to alter the arrangement and make the intake airway the haulage road. If the mine is generating much gas this should be done anyway, especially if the booster is electrically operated. Without making such change, as I said before, the booster should be located near the overcast and outby from the split.

EMPLOYING A "BOOSTER" INSTEAD OF A REGULATOR

I have assumed, as is required by the bituminous law of Pennsylvania, that the principal ventilator is located outside of the mine. If there are no workings outby from the ninth and tenth cross-entries, it is my belief that there would be no advantage in putting a booster fan in this mine at all. What is needed, in that case, is larger airways and better stoppings. If these do not improve the circulation, a larger ventilator must be installed. In my opinion, a booster fan should only be employed to get air into a long split or section of a mine, at such a distance from the fan that otherwise it would be necessary to introduce a regulator in the shorter air split, so as to force more air into the longer split.

I cannot agree with the statement, made in the reply to this inquiry, on page 287, that "the location of a booster fan must always be on the return side and the fan must be operated to exhaust the air from the intake, inby of the leak." It is not always a case of leaky stoppings when a section of the mine is poorly ventilated; I believe that the trouble is usually due to excessive resistance in that section or split. If it were entirely due to leaky stoppings, these could be fixed, in many cases, cheaper than a booster fan could be installed and operated. It is a difficult matter to reduce the length of a split or its resistance, and the only way to get more air into that split is to increase the resistance in other sections, or splits, or to install a booster fan in the long split.

Uniontown, Penn. RICHARD MAIZE, Inspector of Mines.

INQUIRIES OF GENERAL INTEREST

Hauling Capacity of Storage-Battery Locomotives

I have experienced considerable difficulty in the operation of my storage-battery locomotive, which has failed to give me a full active 8-hour day on a single charging. The machine has a 300 ampere-hour capacity at 85 volts; and, as it is operating on a road where the grades do not exceed 3 per cent., it appears to me that this size of battery should yield a full day's work in our mine if suitable equipment is provided.

Thinking over the matter, I had concluded that the trouble is due cheifly, or wholly, to the fact that our mine cars, are the old plain-bearing type, the wheels being somewhat worn run hard. I believe that the excessive friction thus produced is an overtax on the locomotive, causing it to discharge or become very weak, after only about six hours of service.

I was, therefore, contemplating the purchase of new trucks or cars, equipped with the flexible roller-bearing type of wheels, which I have seen advertised in the columns of *Coal Age* for a considerable period. However, chancing to talk the matter over recently with a friend who has been operating mines for a number of years, he told me that I needed a larger locomotive, and stated that, in his opinion, the trouble would not be wholly overcome by the new type of equipment that I proposed to install. He was positive that the locomotive I was using was too small for the work.

Having observed the valuable and helpful assistance that has been afforded inquirers on similar problems through the columns of *Coal Age,* I would like very much to present my proposition and receive such advice as *Coal Age* and its practical readers are able to give. I know of no better plan of gaining valuable information than that presented by the wide circle of friends who contribute their knowledge and experience for the benefit of the industry. I hope that there will be many who have solved difficulties similar to my own and will be willing to give me the benefit of their experience.

Huntington, W. Va. OPERATOR.

We take pleasure in presenting this proposition for discussion, knowing that the broad field of practice represented by the readers of *Coal Age* will yield much helpful advice. We regret, however, that the correspondent has not given much data that are involved in such a problem and which are absolutely necessary to insure an intelligent answer to his inquiry.

While it can be stated with certainty that a great improvement will result from the adoption of flexible roller-bearing equipment, the capacity of the locomotive now in use to perform the required work cannot be told without a knowledge of numerous data not given, such as the weight of the locomotive resting on the drivers, condition of track, length of haul, weight of loaded trip, and last but not least the competency of the motormen. The only data given in the inquiry are the power-rating of the locomotive and the maximum grade of the haulage road.

It is possible, therefore, to offer only a brief suggestion based on the power of the motors, as determined from the given amperage and voltage under which the machine is designed to be operated.

In mine-haulage practice there are two general rules of estimating on the horsepower of a locomotive. One rule makes the effective wattage of the motors, per ton-mile-hour, practically equal to twice the tractive effort of the locomotive, expressed in pounds; and the tractive effort thus determined may be taken as one-sixth of the weight resting on the drivers, dividing by 2000 to reduce to tons.

Applying this rule, in the present case, assuming an efficiency of 90 per cent., the effective wattage derived from the amperage and voltage under which this locomotive is designed to operate is $300 \times 85 \times 0.90 = 22{,}950$ watts. For a speed of hauling of six miles per hour, the effective wattage per mile-hour is $22{,}950 \div 6 = 3825$ watts. Taking this as double the tractive effort of the locomotive gives for the latter.

$$\textit{Tractive effort} = 3825 \div 2 = 1912.5 \textit{ lb.}$$

Again, taking this as $\frac{1}{6}$ of the weight resting on the drivers, the weight of the locomotive available for haulage, in this case, is

$$(1912.5 \times 6) \div 2000 = 5.7, \textit{ say } 6 \textit{ tons.}$$

It may therefore be assumed that, if this locomotive is properly designed and its power properly proportioned to the weight resting on the drivers, the machine in use is a 6-ton locomotive.

Another rule, sometimes used in practice, makes the effective horsepower, per mile-hour, of a properly designed mine locomotive as 9.85 hp., per ton resting on drivers. For a speed of hauling of 6 miles per hour, the required effective power, per ton on drivers, would be $6 \times 0.85 = 5.1$ hp.

Applying this rule, the effective horsepower estimated on the given amperage and voltage, in this case, assuming the efficiency of the motor as 90 per cent., is $0.90\ (300 \times 85) \div 746 = 30.76$ hp. This effective power in a machine designed to haul at a speed of 6 miles per hour would call for a weight of $30.76 \div 5.1 =$ say 6 tons resting on the drivers, as found previously.

Finally, assuming a track resistance of say 15 lb. per ton, the grade resistance for a 3 per cent. grade being $3 \times 20 = 60$ lb. per ton, the total resistance opposed to the tractive effort of the locomotive is $15 + 60 = 75$ lb. per ton of moving load. The tractive effort being 1912.5 lb., the total moving load in this case is $1912.5 \div 75 =$ say $25\frac{1}{2}$ tons. Since this includes the weight of the 6-ton locomotive, the weight of the loaded trip is $24\frac{1}{2} - 6 = 18\frac{1}{2}$ tons that this locomotive would haul up a 3 per cent. grade, under the conditions assumed in the solution of this problem.

EXAMINATION QUESTIONS

West Virginia Examination (1918), Mine Foremen and Firebosses

(Selected Questions)

Ques.—Where would you take your air measurements and how and when would you enter them in the foreman's record book?

Ans.—The law requires (Sec. 64) that the mine foreman shall measure the air current, with an anemometer, at least twice each month, at the inlet and outlet and at or near the faces of the advanced headings; and shall keep a record of such measurements, in a book having a form prescribed by the Chief of the Department of Mines. The measurements should be entered in the book at the time they are taken, the entry being made with ink and dated and signed by the mine foreman as evidence that he has fully complied with the mining law of the state.

Ques.—State in detail what a miner should do on entering his working place and after the firing of each shot.

Ans.—On returning to his working place, after the firing of a shot, the miner should proceed with great caution. In the first place, he should not return until the air current has cleared away the smoke and gas produced by the shot, so that he can see clearly what is before him and discern the character of the roof above him. He must observe the condition of each timber and note if any of them have been misplaced by the shot. He must examine the roof carefully as he proceeds and be particularly cautious as he approaches the place where the shot was fired.

Before attempting to handle any coal for the purpose of loading it into the car, the miner must reset any timbers that have been misplaced by the shot, and examine carefully the face of the coal to see that there is no loose coal hanging and liable to fall. If the mine is generating gas, he must examine to ascertain if any fresh feeders have been struck and note if there is any increased outflow of gas from the coal. Having assured himself that the place is safe for work, he can proceed to set and load his car.

Ques.—Of what use are the following instruments, in and around coal mines: Anemometer, water gage, thermometer and barometer?

Ans.—The *anemometer* is used for ascertaining the velocity of the air passing in an airway, for the purpose of calculating the quantity of air in circulation at that point.

The *water gage* is used for determining the ventilating pressure per square foot of sectional area, at a point in the mine affording communication between the intake and return airways. Each inch of water gage corresponds to a pressure of 5.2 lb. per sq.ft. of section. The reading of the water gage marks the difference of pressure between the intake and return airways, at the point of observation, and shows the pressure required to circulate the air inby of that point. A water-gage reading taken on the fan drift shows the pressure required for the entire circulation in the mine, including the shaft.

The *thermometer* is used to ascertain the temperature of the mine, which is of interest in connection with the hygrometric condition, or the amount of moisture carried in the air. In other words, the capacity of the air for absorbing moisture in the mine and rendering it dry and dusty.

The *barometer* is used to observe the changes in atmospheric pressure, which suggest, to a greater or less extent, the gaseous condition of the mine. A falling barometer indicates a decrease of atmospheric pressure, which is liable to be accompanied by an outflow of gas from the abandoned workings, void places and other reservoirs of gas, in the mine or the strata overlying the openings in the seam.

Ques.—(a) What supplies are necessary in and around the mine, for the safe working of the same? (b) What is your duty and what would you do if these supplies were not on hand?

Ans.—(a) Supplies of timber, rails, tracking and all other material used in the mine, together with first-aid outfits, including stretchers, blankets, waterproof coverings, and suitable means for conveying the injured from the mine and giving them first-aid treatment should always be kept on hand at every mine, and be in a condition ready for instant use when needed. There should also be kept on hand a sufficient supply of tools and repair parts, powder, oil, etc.

(b) It is the duty of the mine foreman to see that all needed supplies are kept constantly on hand and available for use. In case supplies are not available at the mine, it is the duty of the foreman to notify the operator or agent of the mine, in writing, as required by law (Sec. 72), stating his inability to comply with the requirements of the law, owing to the lack of supplies. Sec. 39 of the law provides a penalty for any operator refusing to furnish the supplies necessary for the mine foreman to comply with the law.

Ques.—(a) What qualifications should a miner possess before letting him work alone? (b) What tools should every miner be required to have on hand in order to make his place safe?

Ans.—(a) Before any miner is permitted to work alone he should be required to demonstrate his ability to mine coal safely and to perform all the work required of the miner, including the timbering of his place and the shooting and loading of his coal. He must be able to detect the presence of gas, observe dangerous roof and be familiar with the mining laws and the mine rules and regulations relating to safety.

(b) In addition to the miners' tools, such as picks, drills, tamping rods and needles when the shots are fired by squibs, every miner should have an axe, saw

COAL AND COKE NEWS

Harrisburg, Penn.

With a view to drafting a comprehensive and fair standard of rates for insurance carried by coal operators under the compensation act, and especially for the anthracite operators, a conference was held in Wilkes-Barre on Sept. 19, with operators, officials of insurance companies, mine inspectors of both the bituminous and anthracite fields and officials of the State Department of Mines. The need for readjustment of insurance rates under the compensation law has existed for several years, as anthracite operators and the Associated Companies have protested that the standards now set apply only to the soft coal regions.

The conference, which was a lengthy one, and included the presentation of many technical statements and reports, revealed that during the several years since the schedule was made up safety appliances and methods in the mines have been so improved that some decrease in the rates may be expected.

One of the most important questions taken up was whether or not the State Department of Mines would consider an anthracite mine as "nongaseous" if no gas had been found in a mine for a period of one year or more. If they would approve this, the Insurance Companies stated that they would allow the mine to receive the "non-gaseous" rate. The Chief of the Department of Mines, Seward E. Button, stated that while only a section of a mine may give off gas, it was the custom to class this as a "gaseous mine." He contended that a mine may not generate gas for two or three years, yet a pocket of gas could be found at any time, and cited many instances to prove his contentions and would not agree that the Department of Mines should class a mine as "nongaseous" when it was possible that gas might be found any day.

An effort was also made by several insurance companies to exclude the use of the Davy lamp in the schedule, but nothing definite was decided and will not be for some time. A slight decrease of rates is looked for.

Investigation of all workmen's compensation awards commuted or permitted to be made in a lump sum payment to a Pennsylvania workman permanently injured in an accident will be made by the workmen's compensation Board.

The Board has announced it will discourage lump-sum payments of compensation, excepting when the claimants desire to use such commuted funds in the purchase of artificial appliances or for occupational training to equip themselves for their old tasks or a new occupation.

The census ordered by the compensation board to obtain the histories of all commuted cases during 2½ years that the board has been in existence is the first action of this kind taken by any compensation board or industrial commission of the United States in an effort to replace permanently disabled men in industry at proper tasks. It is believed that a large percentage of these cases can, by proper direction be returned to industry at a benefit, both to the injured men and to industry itself.

Holding in effect that an employee who has finished his work remains under the provisions of the compensation act until he has left the plant or property of his employer, Judge O'Boyle (Luzerne County) by an interesting opinion on Sept. 23 reversed the judgment of the Workmen's Compensation Board in the case of Bridget Tigue against the Forty Fort Coal Co., and directs compensation for the plaintiff in the sum of $1543.

The case is rather unusual. William Tigue, late husband of the plaintiff, was employed as a miner in the Forty Fort colliery of the defendant company and on Dec. 18, 1916, while walking from the shaft toward his home within the inclosed colliery yard of the company along the railroad used regularly by himself and other employees, was struck by a locomotive of the Lehigh Valley R. R. and killed.

When the case was first submitted to the referee he found for the plaintiff that she was entitled to compensation, but the Compensation Board on appeal reversed the decision of the referee, and then the case was sent to the court for a ruling.

The company denied liability because the decedent was not in the course of his employment when killed and that his death was not due to the condition of the defendant's premises, but to the Lehigh Valley R. R. engine. The court, however, holds that Mr. Tigue was doing something in the course of his employment from the moment he entered the inclosure on his way to work until he left the premises and got outside the inclosure on his way home, and that his death was due to conditions on the premises of the defendant company.

Uniontown, Penn.

Responsibility for providing fuel of such quality and in such quantity as to keep the blast furnaces operating at maximum capacity during the coming winter was squarely accepted by 300 representative operators of the Connellsville regions at a meeting here which was addressed by high officials of the United States Fuel Administration. By formal resolution the operators authorized the fuel chiefs to deliver personally to President Wilson upon their return to the capital a message to the effect that "the furnaces shall not bank because of lack of production of the Connellsville coal and coke region."

While the output of the local regions has shown a steady improvement since the perfection of Production Manager Byers' organization the program of that department calls for an increase of approximately 75,000 tons weekly by the middle of October. Mr. Byers announced at the meeting that the regional fuel administration had set the second week of October as the banner week of the year, and that an output of 800,000 tons was the goal of the fuel drive.

Fuel production for the week ending Sept. 14 exceeded all previous records of the region, showing an increase of 18,400 tons in coal over the previous week, which had also established a new record. The coke production for last week was 346,958 tons and the coal output was 216,184 tons. Reduced to terms of coal the total production for the region was 736,621 tons.

An outline of the fuel administration distribution department, as well as the reasons for establishing a rigid inspection of all coke shipments, was given by J. D. A. Morrow. Although there are 46 more blast furnaces now than a year ago, he declared, the steel output will be 4,000,000 tons less. That situation was mainly brought about by lack of quality in the coke, and he warned the operators that no action would be too drastic for the fuel administration to take to correct that evil. He talked in very plain language and his meaning was unmistakable.

Charleston, W. Va.

Much tonnage was lost in the Pocahontas and Tug River districts during the week ending Sept. 19 mainly because of labor shortage. The loss due to car shortage was only 2052 tons, while labor shortage caused a loss of 52,271 tons. The total tonnage produced during the period already mentioned was 433,013, representing a decrease of about 5000 tons as compared with the previous week. Coke manufactured was about the same as for the week previous, or 49,829 tons. Efforts are being made to take up the slack at the mines because it is getting to be too often the case that miners in the Pocahontas and Tug River Districts fail to work up to capacity.

The greatest drawback to increased production in the Fairmont District is the late placement of cars, which seems to have now become a chronic condition in that field. For instance, last Saturday (Sept. 21), while the district was furnished with 1142 cars at 7:00 a.m., only 621 cars had been placed by the B. & O. The car supply itself has been none too good, not averaging much over 1200 cars a day, which is below the maximum requirements of the district. The production in the district as a whole has also been curtailed by an order issued which makes it impossible for team track loaders to get any cars at all for loading coal. They are not even to be allowed to load cars emptied on an agent siding. The order has completely paralyzed operations of team track loaders in this section. Complaint is made by mines in the district and specific instances cited showing that cars have been taken from coal operators and sent to plants for the loading of non-essentials. For three days last week there were no placements of cars on the M. & K. R.R. Twenty-one coal mines and four coke ovens with a capacity of 110 cars, in the Preston-Monongalia field, were shut down because of such a car shortage.

Coal production in the Winding Gulf district for the week ending Sept. 14 totaled 123,471 net tons, an increase of 6734 net tons over the previous week. This is regarded as satisfactory in view of the holiday loss. Still further production gains were scored during the week ending Sept. 21 in the New River and Winding Gulf fields, the increase for the combined districts being in the neighborhood of 5000 tons. Results are being achieved in the movement for increased production under the direction of E. E. White, production manager, and continued increases in production are expected by coal operators.

Though the New River district mines had a 100 per cent. car supply last week, production was seriously curtailed when a large number of the miners took a day off on Monday the 16th to hunt squirrels. Two-thirds of the miners out of one mine alone, as an instance, were absent from their posts.

Had all the mines in the Kanawha region reported this week it would have shown a total production of over 200,000 tons. With reports from seven mines lacking, the officially reported total production was 196,587 tons, representing an increase of 8000 tons reported over the preceding week, the hours required to produce such a tonnage being 5847. Car shortage has been reduced to 359 hours and labor shortage was only 675 hours. Mine disability represented a loss of 489 hours. While the car supply was not 100 per cent. it was almost that.

Birmingham, Ala.

Greatly improved output of coal in the Birmingham District during the next few weeks is expected, due to full resumption of mining operations at the Lewisburg mines of the Alabama Co., renewed efforts of the Railroad Administration to satisfy the full car demands of the mining interests here, and the efforts of the miners to turn out greater supplies of coal.

Coal production during the week of Sept. 21 promises to show greater increase than that for any week in some time, for the reason that the low water mark was reached during the previous week, when only 385,621 tons was the reported coal output of the district's coal mines, according to figures compiled by the local office of the Fuel Administration. Production for the week just ended is estimated at 395,000 tons, roughly. Experts say the output should not drop below the 400,000-ton mark in the future, and the 450,000-ton mark is confidently expected for future weeks.

Mining operations have been begun at the old Bamford mines, which have lain idle for the past twelve years, with Birmingham operators in charge. The coal at these mines is of a good grade and runs from three to five feet. The mine was found in workable condition after long idleness, but the new owners have put in many improvements, including a new spur track to the main line of the Southern R.R., from which it is only a 12-mile haul to Bessemer. It is understood that the entire output of the mine has been contracted for.

Tonnage figures for coal production during the past two and a half months are as follows, by weeks: Week ending July 13, 412,478; July 20, 415,653; July 433,738; Aug. 3, 417,462; Aug. 10, 427,718; Aug. 17, 411,035; Aug. 24, 430,311; Aug. 31, 390,413; Sept. 7, 392,939; Sept. 14, 385,621.

Dallas, Tex.

About a score of new coal mines are to be opened in the McAlester-Wilburton coal fields, according to reports in McAlester, Okla., following the action of the War Industries Board in approving the applications of these companies. Something like 700 applications for authority to open new coal mines were made to the War Industries Board by operators in the McAlester-Wilburton section, and of this number only about 20 were approved.

The first report from Washington that the War Industries Board would frown on the establishment of new industries was followed by a period of marked inactivity, for there was an inclination to take this order at its face value without investigation. Later it was explained that the desire of the Board was to encourage all essential industries, particularly the production of coal, and that steps should be taken at once to place details of the proposed new development before the Board for formal action. Then followed a period of marked activity during which the propositions for the opening of many mines were placed before the Board.

The War Industries Board in acting on these propositions has explained that the mere production of coal is not all that is required to get approval of a proposal to open a new coal mine or to develop idle coal lands. The quality of the coal must be considered, the labor supply available for operating the coal mine without interfering with other essential industries, ability of the railroads and other transportation systems to move the coal from the mines to points of consumption, and finally the amount of coal that can be produced from the proposed mine, are factors that largely determine whether or not the new mine will be allowed to be developed.

Lack of transportation facilities was the chief reason for the disapproval of the applications from many of the Oklahoma concerns, and poor quality of coal to be produced ranked as a second reason for refusal.

PENNSYLVANIA

Anthracite

Sugar Notch—Two members of the surveying corps for the Lehigh and Wilkes-Barre Coal Co., while working in the No. 9 colliery of the company on Sept. 20, were burned when an open lamp ignited a pocket of gas.

Avondale—Four employees of the Delaware, Lackawanna & Western Railroad Co. were burned by an explosion of gas on Sept. 20, shortly after the beginning of operations. The two laborers had stood a set of timber near their chamber the night previous and were placing "cogging" about it the next morning. Shortly after the miner entered with a naked lamp and, encountering a pocket of gas, the lamp exploded, burning the men severely. They were all removed to the State Hospital.

Lattimer—Complaint was made on Sept. 23 by coal companies that the agreement which was drawn up this summer that one war industry would not recruit new hands from another plant engaged in Government work is being violated. C. Pardee & Bros. charged that their staff of miners has been raided and that nine have been located in a war plant nearby. The War Labor Board will be asked to act.

Hazleton—Despite the heavy rains in the past week the anthracite coal mines in the Lehigh region have not been affected by high water, and production has not been interfered with to the least extent. The precipitation was so gradual that pumps were fully able to handle the situation. The rains have refilled reservoirs that were low and there is no further scarcity of water anywhere throughout the district.

While wartime prohibition does not become effective until July 1, this town is already feeling the effects. So far this month (Sept. 22) only eight men have been arrested by the police on charge of intoxication, a record of which Mayor Heidenrich said he feels proud. Usually arrests for this misdemeanor exceeded all others, and were especially numerous around paydays at the mines. The falling off is attributed to the spread of the "dry move" and the high cost of liquor as a result of wartime conditions.

Mauch Chunk—The Lehigh Coal and Navigation Co. is planning for the reopening of the abandoned anthracite mine near Summit Hill.

Bituminous

Pittsburgh—The plant of the Orenstein-Koppel Co. at Koppel, Beaver County, Penn., has been sold by Alien Property Custodian Palmer to W. A. Chamberlain, auditor of the Pressed Steel Car Co. for $1,312,000. The 3000 shares of stock held by the German interests were sold to Hamilton Stewart, representing the Mellon interests of Pittsburgh, for $100.75 per share.

Uniontown—G. S. Harsh, L. W. Fogg and John A. Thompson, receivers of the Tower Hill-Connellsville Coke Co., have finished their labors and turned the property back to the stockholders of the corporation. J. R. Nutt, of Cleveland, Ohio, treasurer of the company, acknowledged the return for the corporation.

Greensburg—Joe Petris and Steve Stanton, firemen, were killed and two others are seriously injured as the result of a boiler explosion in the power house of the Westmoreland Coal Co. at Rillton, near here. Four boilers exploded and the escaping steam filled the boiler house. Other boilers remained intact and heroic workmen kept up steam to run the cages in order to hoist the 300 workmen from the mines. Repairs are rapidly being made and work will be resumed in a few days.

Black Lick—The Jewel Coal Co., controlled by men from Indiana, are constructing a siding, tipple, etc., preparatory to making shipments from its mines near Josephine. An incline plane will be constructed from the mine to the tipple and it will be necessary to build a two-span bridge over Black Lick creek to reach the railroad siding. The mines are now operating with a capacity of about 200 tons per day, the coal being hauled by teams and trucks. The capacity will be doubled upon completion of the tipple. Shipments will be made from the Cresson branch of the Pennsylvania Railroad.

WEST VIRGINIA

Bluefield—All office and store employees of the Panther and Lathrop Coal companies, operating in the Pocahontas field at this place, have entered into an agreement to go into the mines each and every Wednesday night to help load coal as a war measure and to donate the proceeds from such work to the Red Cross. This action was the climax to a meeting of the miners of the two companies held to name representatives of the miners on production committees.

Charleston—Such rapid progress has been made on the construction of the plant of the Big Bottom Coal Co. at Tad, on Campbells Creek, that the company will be able to begin the mining and shipment of coal in about ten days. The general manager of the new company is J. S. Cheney, of Charleston.

Dingess—The first coal company to be closed in district No. 9 on account of loading dirty coal is the Chafin and Hatfield mines at Dingess. This operation was closed by orders of the National Fuel Administration, effective Sept. 21. Numerous complaints were received by the consumers and manufacturing plants because of the bad quality and low grade of coal sent out by some of the mines, and as a result the announcement was made that after a certain number of offenses the mines found guilty would be closed. This suspension will remain until otherwise ordered by the Government.

OHIO

Athens—The labor train arranged for by the Buckeye Coal and Railway Co. to run from Athens up Bailey creek to supply a number of the company's operations in that field has been started by the Hocking Valley Railway Co. It required a month for the railroad company to find the three passenger cars necessary after the running of the train had been approved.

KENTUCKY

Hazard—Fire destroyed the power plant of the Hazard Coal Co. on Sept. 21, it being reported that the loss was heavy. The company will rebuild immediately.

Henderson—The Louisville, Henderson & St. Louis Railroad Co. on Sept. 23 lost a coal tipple valued at $10,000 in a fire at Henderson, which is supposed to have been started by rail tramps who had been sleeping in the tipple.

TENNESSEE

Chattanooga—The Chattanooga Iron and Coal Co., Chattanooga, Tenn., suffered severe damage to the engine room and dry blast tower when fire started in the oil storage room and spread to other sections of the plant.

ILLINOIS

Marissa.—The Aluminum Ore Co., of East St. Louis, has been leasing coal lands in the Darmstadt neighborhood between here and Lenzburg, with the intention of establishing a mine and operating it for a fuel supply for its big plant.

O'Fallon.—Samuel Meister, of Bay City, Mich., has been obtaining options on coal lands in this vicinity for a new company which is planning to take over and operate the mine formerly known as the O'Fallon Coal and Mining Co. Meister is offering $50 a ton for the coal rights and 5c. a ton for all coal hoisted.

Freeburg.—The Mulberry mine, near here, has been purchased by a newly organized company, the New Era Coal Co., which has been incorporated at Springfield with a capital stock of $25,000. The incorporators are H. B. Kooser, T. H. Gorman, L. Weiler and F. A. Friend, all of St. Louis. The mine employs about 100 men.

Oglesby—The Oglesby Coal Co.'s mine has been closed under an injunction issued by Judge Sanborn of Chicago. The injunction, which is a permanent one, was granted to prevent mining under the property of the Marquette Cement Co.'s property. The closing of the mine came as a great surprise to the officials of the mining company, especially at a time when the production of coal is being speeded up over the entire country.

Personals

E. W. Hoffman has resigned his position as superintendent of the mines of the Meco Coal Co. on Yellow Creek, near Homer City, Penn.

M. J. Zuby, formerly mine foreman for the Tide Coal Mining Co., at Tidedale, Penn., has been made superintendent of the mines of the Meco Coal Co. near Homer City, Penn.

Frank Farrington, president of the United Mine Workers of Illinois, was married Sept. 19 to Miss Alberta May Applewhite, at her home, 20 Campbell Ave., Indianapolis, Ind.

Eugene Jenks has been promoted from chief engineer of the Cowanshannock Coal and Coke Co., at Yatesboro, Penn., to superintendent of the No. 5 mines of the same company at Nu-mine, Penn., to succeed William Craig, resigned.

G. W. Colson, general manager of the Logansport Coal Co., Logansport, Penn., has been appointed general manager of the Pittsburgh & Allegheny Coal Co. and Pittsburgh & Clarion Coal Co. Mr. Colson has had considerable experience both in the United States and in European coal fields.

Thomas Bevan, of Scranton, Penn., has been appointed by W. W. Inglis, vice-president and general manager of the Delaware, Lackawanna & Western R. R., as general storekeeper of the coal mining department. Mr. Bevan was for seventeen years connected with the electrical department of the coal offices.

A. J. Case, formerly mine foreman of the Lucerne mine of the Rochester and Pittsburgh Coal and Iron Co. at Lucerne, Indiana County, Penn., has been promoted to superintendent of the Jacksonville mines Nos. 1 and 2 of the Jefferson and Clearfield Coal and Iron Co., at McIntyre, Penn., to succeed H. B. Stamper, resigned.

Obituary

Jack H. Morrison, aged 49 years, member of the firm of the Central Coal and Coke Co., of Carson, La., and superintendent of this company's properties in Louisiana, died at San Angelo, Texas, on Sept. 19, following an attack of appendicitis. Mr. Morrison at the time of his death was a member of the Government price-fixing committee on lumber.

Lieutenant George T. Rodgers, of Headquarters Company, 110th U. S. Infantry, was killed in action in France July 29. He was formerly a member of Company F of the Old Tenth Regiment of Pennsylvania and was promoted to a First Lieutenant before going over. At the time the United States entered the war Rodgers was division engineer of the Jefferson and Clearfield Coal and Iron Co., with headquarters at Indiana, Penn. His home was in Brookville Penn., and his mother and one sister survive him.

Publications Received

Petroleum: A Resource Interpretation. By Chester G. Gilbert and Joseph E. Pogue. Smithsonian Institution, United States National Museum. Bulletin 102, Part 6. Illustrated, 74 pp., 6¼ x 9¾ inches.

The Diesel Engine, Its Fuel and Its Uses. By Herbert Haas. Department of the Interior, Bureau of Mines. Bulletin 156. Petroleum Technology No. 44. Illustrated, 122 pp., 6 x 9 inches.

Annual Report of the Minister of Mines for the Year Ending Dec. 31, 1917. An account of mining operations for gold, coal, etc., in the Province of British Columbia. Illustrated, pp. 485, 7½ x 10½ inches.

Trade Catalogs

Pneumatic Rotary Dump for Mine Cars. Wood Equipment Co., Chicago, Ill. Bulletin 180. Pp. 12; 8½ x 11 in.; illustrated. Shows some typical installations of the pneumatic rotary dump and gives many reasons why the use of the dump improves mining conditions.

Type FK-20 Oil Circuit Breakers for Industrial Service. General Electric Co., Schenectady, N. Y. Bulletin 47,433. Pp. 16; 8 x 10½ in., illustrated. The circuit breakers described and illustrated run up to 300 amp. and 2500 volts, and are intended primarily for use with induction motors in industrial applications. Under proper supervision they may be used in coal mines.

The Gibbs Oxygen Breathing Apparatus. Mine Safety Appliances Co., Pittsburgh, Penn. Bulletin O-104. Pp. 20; 6 x 9 in.; illustrated. An interesting booklet containing an account of the development of the Gibbs apparatus, and listing the general requirements with which an efficient breathing apparatus should comply. The Gibbs device has been adopted for use by the U. S. Bureau of Mines and is made in America by American workmen.

Watt Cars—Mining and Industrial. Watt Mining Car Wheel Co., Barnesville, Ohio. General Catalog. Pp. 156; 8½ x 11 in.; illustrated. A splendidly prepared catalog, and one beyond criticism from any point of view. The typography, illustrations and paper are of the finest. Many of the company's most successful types of mine cars are described. The catalog is divided into five sections, embracing mining cars, industrial cars, ore cars, wheels and couplings.

Coming Meetings

Coal Mining Institute of America will hold its its annual meeting Dec. 4 and 5 in Pittsburgh, Penn. Secretary, H. D. Mason, 911 Chamber of Commerce Building, Pittsburgh, Penn.

American Institute of Mechanical Engineers will hold a meeting of the Middle West sections on Oct. 25 and 26 at Indianapolis, Ind. Secretary, Calvin W. Rice, 29 West 39th Street, New York City.

Industrial News

Mobile, Ala.—The National Coal Co. has increased its capital from a nominal $2000 to $20,000.

Hazard, Ky.—The Kentucky Block Coal Co. has increased its capital from $35,000 to $100,000.

Hazard, Ky.—The Lots Creek Coal Co., Hazard, Ky., has increased its capital from $60,000 to $100,000.

Colmar, Ky.—The Long Ridge Coal Co. has filed notice of an increase in its capital from $20,000 to $50,000.

Columbus, Ohio—The Strabley Co. has been incorporated with a capital of $150,000 by John H. Price and others.

Girdler, Ky.—The Steele & Alder Coal Co., capital $18,000, has been incorporated by P. M. Alder, W. B. Steele and Rex E. Steele.

Miami, Okla.—The Eagle Picher Mining Co. is said to be considering plans for the development of coal properties in the vicinity of Miami.

Harlan, Ky.—The Upper Harlan Coal Co. has filed notice of an increase in its capitalization from $60,000 to $100,000 to provide for expansion.

Thurber, Tex.—The Texas & Pacific Coal Co. has filed notice of an increase in its capital from $3,000,000 to $4,000,000 to provide for business extensions.

Pikeville, Ky.—The Fannin Coal Land Co. has been incorporated by J. M. Fannin and associates to operate coal properties in this section, with capital of $50,000.

Hazard, Ky.—The Yerkes Mining Co., capital $1500, has been incorporated by J. E. Baker, W. A. Stanfill and others to enter the coal mining business.

Louisville, Ky.—The Louisville Soap Co., Floyd Street, has had plans prepared for the construction of a series of new coal hoppers at its works to cost about $9000.

Pittsburgh, Penn.—The Pittsburgh & Lake Erie R. R. has commenced excavations for a new coal-handling plant at Brightwood, Penn., to cost about $250,000.

Albany, N. Y.—The New York Central R. R., St. Lawrence Division, is having plans prepared for the construction of a new mechanical coaling plant at Ogdensburg to cost about $30,000.

Muskogee, Okla.—The Baxter Springs Coal Mining Co. has been organized at Muskogee with a capital stock of $20,000. The incorporators are J. T. Sartin, W. O. Manley and C. M. Bowles.

Philadelphia, Penn.—Director of Supplies Joseph S. MacLaughlin has made application to the City Council for an appropriation of from $250,000 to $300,000 for coal for the municipal buildings.

Beattyville, Ky.—The Mekes Branch Coal Co., Beattyville, one of the Kentucky river mining companies, has changed its name to the White Ash Fuel Co., and increased its capital from $25,000 to $50,000.

Charleston, W. Va.—Numerous improvements are being made at the plant of the Barren Creek Coal Co., at Queens Shoals, with a view to increasing the output. This plant is under the management of J. R. Ramage.

Richmond, Va.—The Raven Coal Co. has been incorporated with a capital of $500,000 to operate coal properties. J. E. Hall, Bluefield, W. Va.; Justin J. Stevenson and Willard S. Holcomb, Columbus, Ohio, are the incorporators.

Longstreth, Ohio—The Locke Coal Co. has been chartered with an authorized capital of $30,000 to mine and sell coal. The incorporators are Frank Locke, John Turner, Herbert Locke, Charles Locke and Edwin D. Ricketts.

West Philadelphia, Penn.—The Pennsylvania Railroad Co., 3200 Powelton Ave., Philadelphia, has awarded a contract to Brann & Stuart, Commercial Trust Building, for extensions in its coal wharf No. 2 at West Philadelphia.

Sewelton, W. Va.—The Sewelton Coal Co. has been incorporated with a capital of $150,000 to operate coal properties in the Sewelton section. E. F. and J. W. Graham and W. A. Charlton, all of Hinton, W. Va., are the incorporators.

Roanoke, Va.—The Kentucky Cardinal Coal Corporation has been incorporated with a capital of $250,000 to develop coal lands in the Roanoke field. J. C. Stras, Roanoke, is president; and J. A. McQuail, Hiawatha, Va., is secretary.

Pittsburgh, Penn.—The La Belle Coal Co. has purchased a tract of about 44 acres of coal lands in Harmar Township for a consideration of about $30,000, and is understood to be planning for the early development of the property.

Zanesville, Ohio—The Western Pennsylvania Coal Co. has been incorporated with a capital of $225,000 to mine and sell coal. The incorporators are L. B. Burger, Joel R. Lewis, Samuel H. Sedwitz, David J. Lewis and Joseph Goldberger.

Beech Creek, Ky.—The Kirk Coal Co. which recently filed notice of an increase in its capital from $10,000 to $100,000, is now developing approximately 250 acres of coal properties in the Beech Creek section, having a capacity of 500 tons daily.

Madisonville, Ky.—The Circle City Coal Co. has plans for improvement of its tipple facilities, these plans calling for abolishment of the present incline to the tipple and installation of automatic machinery to lift the mine cars to the tipple for dumping.

Pittsburgh, Penn.—The Pitcairn Gas Coal Co. has recently taken title to about 11 acres of coal properties in Patton township for a consideration of approximately $15,000. It is said that the company is planning for early development operations.

Splash Dam, Va.—The Sutherland Coal Co. has been incorporated with a capital of $50,000 to engage in the development of coal properties in the vicinity of Splash Dam. S. H. Sutherland, Clintwood, Va., is president; and T. L. Sutherland, Lebanon, Va., is secretary.

Heidelberg, Penn.—The M. C. & H. Coal Co., recently organized, is planning for the development and operation of about 50 acres of coal lands in this vicinity. The initial plant to be installed will have a capacity of about 25 tons a day. Patrick Henry is secretary-treasurer.

Charleston, W. Va.—The Booker Washington Development Co. has been incorporated with a capital of $100,000 to operate coal properties in the Charleston district. I. Shuster and John P. Swanson, Danville, Va., and T. B. Bowman, Charleston, are the principal incorporators.

Bradford, Penn.—The Natural Resources Development Corporation has been incorporated in Delaware with capital of $25,000,000 to develop and operate coal, oil and natural gas properties. Carl K. Dresser and James P. Ryan, Bradford; and A. M. Bush, Tulsa, Okla., are the incorporators.

Mount Morris, Penn.—The Mount Morris Coal Co., recently organized, is planning for the development and operation of about 200 acres of coal lands in the vicinity of Morgantown, W. Va. Mining equipment, including electrical machinery, will be installed at the property. M. B. Clovis is president.

Pittsburgh, Penn.—D. Kirk, chief engineer of the Pittsburgh Terminal Railroad and Coal Co., is considering the reconstruction of the tipples at mines Nos. 6 and 7, located about 10 miles from Pittsburgh on the Monongahela River and the old Wabash R. R., now used by the Western Maryland Railroad.

Oklahoma City, Okla.—The Oolagah Coal Co. of Enid, Okla., has been organized and charter filed in the office of Secretary of State Lyon at Oklahoma City. The company is capitalized at $300,000 and the incorporators are Robert D. Anderson, O. A. Triplett, both of Enid, and Henry Flanders, of Weimer, Okla.

Charleston, W. Va.—Anchor Coal Mining Co., Morgantown, W. Va. Capital stock, $100,000. To operate mines in Monongalia County and elsewhere in West Virginia. Incorporators, John C. Pollock, of Fairmont; Wilford B. Grim and E. A. Allen, of Shinnston; Ernest H. Gilbert and Mable Wilson, of Morgantown.

Louisville, Ky.—The Pittsburgh Coal Co., which in past years handled river coal from barges almost exclusively, is now handling considerable quantities of rail coal, including western Kentucky. At the present time the company is endeavoring to locate a new or second-hand locomotive crane to aid in unloading and handling coal in the yards.

Joplin, Mo.—The Lightning Creek Coal Co., will start work Oct. 1 on the development of its coal mine near Pittsburg, Kan. About $25,000 is to be expended. Material and equipment needed and not yet purchased include coal cars, concrete, boilers, hoist, lumber, roofing, steam engine, wire cable, etc. P. E. Tabor is superintendent in charge.

Charleston, S. C.—In connection with extensive improvements to practically double the present capacity of its plant, the Charleston Consolidated Railway and Lighting Co. is planning for the installation of new coal and ash-handling equipment at the Charlotte St. generating station. The entire expansion program is estimated to cost about $700,000.

Baxter Springs, Kan.—Work will be started Oct. 1 by the C. and M. Mining Co. on the development of its coal property near here. The estimated cost of the proposed plant is put at $25,000. Equipment and material not yet purchased include a steam shovel, engine, boilers, concrete, screens, belt, tracks and cars. G. R. Cook is the superintendent at the works.

Beaumont, Tex.—The Texas Steel Co. has acquired a tract of coal property near Birmingham, Ala., and plans to develop the lands for a production of over 150,000 tons a month. The site is located in the Warrior River district, and in connection with the proposed coal plant a coke works is contemplated, to be used for the company's steel works at Rusk, Texas.

Clarksburg, W. Va.—Clarksburg will be the headquarters of the Clarksburg Domestic Fuel Co., which will develop coal lands in Harrison County, the company having been granted a charter by the secretary of state. The incorporators are Thomas J. Francis, J. H. Stephenson, Robert Shuttleworth, Edward W. Laubenstein and Louis E. Dorsey, all of Clarksburg.

Oakland, Md.—The Freeport Coal Co. is planning for the development of about 300 acres of coal lands near Corinth, W. Va., and proposes to provide a plant with an initial capacity of about 100 tons a day. A housing settlement for employees at the mines will also be established. The company has recently increased its capital from $25,000 to $100,000. R. T. Thayer is superintendent.

St. Louis, Mo.—An inventory of the estate of Charles E. Gartside, former president of the Gartside Coal Co., filed in the Probate Court, shows that he left a personal estate of $217,002.25, on which $210,500 was in bonds. One-half of the estate was bequeathed to his wife and the other half to a niece and three nephews, one of whom is Robert A. Niggeman, president of the Gartside company.

Springfield, Ill.—The skip-stop system installed by the Springfield Consolidated Railway Co. will save 10 per cent. of the coal normally consumed. Twenty-five per cent. more will be saved by the elimination of part of the heating and lighting of the cars. The normal consumption by the Springfield Consolidated Railway Co. and the Springfield Gas and Electric Co. is 100,000 tons annually.

Columbus, Ohio—The Arrowhead Coal Co., recently chartered with a preliminary capital of $1000, which will soon be increased one hundred fold, has acquired a tract of 1000 acres of coal lands in Perry County, on the Pennsylvania, which will be developed by stripping. Machinery has been ordered and it is expected that coal will be loaded in 60 days. The overburden is about 20 ft. on the average.

Charleston, W. Va.—Former Judge H. D. Rummel, of the Common Pleas Court of Kanawha County, heads the newly organized Central Byproducts Coal Co., which will establish a plant in Big Sandy District of Kanawha County, representing an expenditure of about $60,000. The incorporators, in addition to Judge Rummel, are H. S. Rummel, H. T. Smarr, D. O. Blagg and J. C. Morris, all of Charleston.

Bellaire, Ohio—The shaft mine of the Captina Coal Co., which is located at Armstrong, has been taken over by A. A. Minder, Robert Matnice, James F. DuBois and Charles Wise, all of Bellaire. The new owners, who intend to secure a charter, will soon start development work looking to an increase in output. The mine will be electrified and new equipment and material will be purchased. William Rennie is superintendent in charge of operation.

Pittsburgh, Penn.—A deal is pending between the General Edison Company of New York, and D. B. Zimmerman of Somerset, Penn., president and chief owner of the Quemahoning Coal Co., operating several mines in Somerset County, for the purchase of the latter company and the Indian Creek Railroad, connecting with the Baltimore & Ohio R.R., and serving some of the mines. The remaining mines are on the Baltimore & Ohio Railroad.

Morgantown, W. Va.—Taylor County people are behind a new coal venture in Monongalia County and plan to operate mines in that county near Opekiska, the company to be known as the Somerville Coal Co., whose chief office will be established at Grafton. The company has an authorized capital of $30,000, the incorporators being Eugene Somerville, Laura E. Somerville, Mary M. Somerville, Mary S. Holden and Rufus Holden, all of Grafton.

New York, N. Y.—The United States Steel Corporation is said to have acquired a tract of about 12,000 acres of coal property located on the Monongahela River in the northern section of Greene County for a consideration understood to be in excess of $4,000,000. It is said that the company will soon commence operations for the development of the properties, which will produce coking coal exclusively, and will be used in the various furnaces of the company.

Oklahoma City, Okla.—City officials of Oklahoma City have decided to establish a municipal coal yard. Contracts for a coal supply will immediately be made. This will not interfere with local coal yards, but coal will be sold from the municipal yard when other coal yards are out, and the poorer classes will be served first. According to Allen Street, county fuel administrator, not more than one in twenty families in Oklahoma City have provided a coal supply for the winter.

Charleston, W. Va.—Further development of coal lands near Hartland, in Clay County, will be undertaken in the near future by the Clay County Fuel Co., which has a capital of $100,000, Charleston and Philippi business men being chiefly interested in the new venture. The principal figures in the new company are S. A. Moore, of Charleston; A. J. Peck, of Charleston; William Taylor George, of Philippi; H. J. Wilcox, of Philippi; A. A. Lilly, former Attorney General, of Charleston.

Chicago, Ill.—The general offices of the Wood Equipment Co., manufacturers of the Pneumatic rotary dump, have been moved from the McCormick Building to 1220 East 75th St., Chicago. The company has acquired a large tract of land fronting on the Illinois Central R. R., together with a number of buildings, including a workshop. The growing demand for the company's product will necessitate the enlargement of the factory facilities, and new construction will be undertaken as soon as conditions permit.

Newark, N. J.—The Burnrite Briquet Co., of Newark, N. J., has filed plans for its proposed new manufacturing plant at Avenue A, Alpine and Earl Streets, to cost $95,000. The initial works will consist of five one, two and four-story buildings for general manufacturing, as follows: One, two and four story main structure, 66½ x 88 ft.; one-story, 52 x 54 ft.; one-story, 42 x 42 ft.; two-story, 24 x 40 ft.; and one-story, 31 x 164 ft. A steel coal conveyor trestle, 280 ft. long, to cost about $7000 will also be constructed.

Indianapolis, Ind.—Plans for the formation of a protective organization by Indianapolis coal dealers to stop the theft of coal from cars in the railroad yards have been discussed and further meetings will be held. It is estimated that the thefts amounts to $100,000 annually. One dealer reported that his company had lost $7500 in one month through wholesale thefts from cars. Martin Rehfuss, Jr., fuel administrator for Marion County, said that he would coöperate with the coal dealers in their efforts to stop this loss.

Charleston, W. Va.—The Kanawha Collieries Co., Charleston National Bank Building, recently organized, is planning for the immediate development of a tract of coal property of over 1000 acres of a total site of about 2700 acres of land held in the Swiss section of the state. The company will install a complete mining plant for development and operation, consisting of tipple machinery, conveying equipment, mine railway line with cars and other machinery. All equipment will be electrically operated wherever possible, with substation provided for this purpose. William G. Conley is president.

Toledo, Ohio—Dock activity during the week ending Sept. 21 was generally satisfactory, although the tonnage loaded was not as large as during the previous week. Special efforts are now being made to get a large tonnage to the Northwest before the close of navigation. During the week the Toledo & Ohio Central docks handled 73,000 tons as compared with 92,000 tons the previous week, making a total of 1,522,000 tons for the season. The Hocking Valley docks during the same week handled 190,333 tons as compared with 207,000 tons the previous week, making 3,487,000 tons for the season.

Cincinnati, Ohio—The Lunkenheimer Co., manufacturers of high grade engineering specialties, royally entertained the delegates and visitors of the N. A. S. E. National Convention held here during the week of Sept. 9. The company obtained permission to use Cincinnati's wonderful Zoological Gardens, and judging from the large attendance every one visiting the convention was present. It was the consensus of opinion of the delegates and their friends that the Lunkenheimer outing made the 1918 convention one of the most enjoyable and interesting ever given and one long to be remembered.

New York, N. Y.—C. A. Graves has been appointed Administrative Engineer for New York State by Delos W. Cooke, State Fuel Administrator. Mr. Graves was formerly Assistant Administrative Engineer in charge of the New York-Metropolitan District. He is president of the Graves Engineering Company and vice president of the Southern New York Power & Railway Corporation. Previous to his forming the Graves Engineering Co. five years ago, Mr. Graves was power engineer for the Edison Electric Illuminating Co. of Brooklyn, and previous to his work in Brooklyn he was superintendent of power for the Peckham Manufacturing Co., manufacturers of electric railway equipment.

Pittsburgh, Penn.—The Pennsylvania Coal and Coke Corporation, of Cresson, Penn., has commenced the foundation for a new tipple at its Patton mine, to replace the tipple entirely destroyed by fire July 18. Mines Nos. 33 and 37 are located near Patton. Picking belts will be installed for the hand removal of impurities intermixed with the lump size of coal, and and experimental coal-washing jig with the necessary coal-handling equipment will be provided for the removal of impurities intermixed with the nut and slack sizes of coal. During construction of the surface plant coal mined at No. 33 mine will be delivered over Mine No. 37 tipple by underground connection. The entire construction is in charge of H. H. Hasler, mining engineer for the Pennsylvania Coal and Coke Corporation.

Seattle, Wash.—Due to heavy demand for steaming coal for the new government ships and the regular offshore vessels, no immediate relief is in sight for the fuel shortage that is hampering a number of the steamship lines operating out of this port. Curtailment of service may become necessary unless the steamboats change to wood fuel. Increasing output of new Government ships in this district has added immensely to the demand for steaming coal, and the labor shortage in western Washington mines has prevented the mines from meeting this. The movement of 100,000 tons of Northwest coal to Chile, it has been explained by operators, has no effect on the sea situation, as the coal for that country is railroad fuel and is not adapted for ship use.

St. Louis, Mo.—Application of the Laclede Gas Co. to the Missouri Public Service Commission for permission to increase its rates for gas has disclosed that the company is losing $789,000 a year because it is under long-time contracts which cause it to sell its byproducts at less than the market price. The company buys and sells its coke under a reciprocal contract with the Consolidation Coal Co. which does not expire until Dec. 31, 1919. Under that contract the company pays a maximum price of $3.65 a ton for its coal. It receives $4 a ton for gas-oven coke and approximately $5 a ton for its metallurgical coke. Although it gets its Elkhorn coal at $3.65 a ton, while the Government price is $5.15, delivered in St. Louis, its advantage in that respect is heavily overbalanced by the fact that, if it were not for the contract, it would be getting $7.75 for gas-oven coke and $9.90 for metallurgical coke.

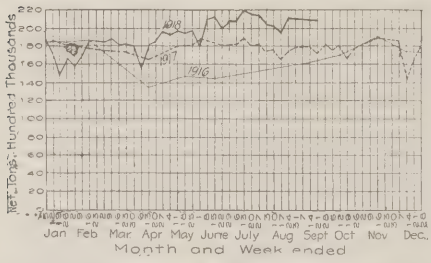
Pittsburgh, Penn.—H. H. Hasler, mining engineer, Pennsylvania Coal and Coke Corporation, Cresson, Cambria County, Pennsylvania, is making a study of the coal seams at mines Nos. 33 and 37 near Patton, mine No. 46 near Winburne, mine No. 8 near Ehrenfeld and mine No. 15 near Beaverdale. The owners have in view the marketing of only well cleaned and sized coal and contemplate removing the impurities loaded in the cars by the miners by hand-picking the larger sizes and washing the nut and slack sizes. They are also seriously considering mechanical appliances for reclaiming the coal values in the extensive refuse pile adjoining mine No. 33. This pile consists of slate, pyrites, bony rock and coal. Preliminary tests show that 25 per cent. of the pile is very fair coal containing on an average 11½ per cent. ash, less than 1 per cent. sulphur, 25 per cent. volatile matter and 63.50 per cent. carbon.

MARKET DEPARTMENT

Weekly Review

Bituminous Mines Slow To React to Stimulation—Soft Coal Output Shows Decline in Spite of Efforts Made To Boost Output—Improvement in Car Supply Discloses Shortage in Man Power—Anthracite Production Falls Off Because of Strike

THE bituminous miner, as a class, does not seem to react noticeably to the many attempts being made to speed him up. In spite of the earnest work of production committees to boost output, in spite of get-together meetings held for the express purpose of acquainting the miner with the importance of his labor to the war program, in spite of an improved car supply and the existence of other favorable conditions, the output of soft coal keeps going down from week to week. During the week ended Sept. 21, the bituminous mines shipped 12,650,000 net tons of coal. This quantity is by no means near the maximum capacity of the mines, though it exceeds by 2,060,000 net tons the output of the corresponding week of 1917. To successfully meet the urgent demands imposed by our war industries the bituminous mines should be working to the straining point, and it is toward this end that the production department of the Fuel Administration is laboring.



As the car supply at the mines continues to improve the shortage in man power makes itself more evident. Labor at the mines is uneasy, and if too hard pressed the worker packs his belongings and goes elsewhere, lured on by the higher rates of wages paid in other industries. It never before was so difficult to maintain a spirit of contentment in the mine worker, and this is undoubtedly responsible for the poor showing made by some operations.

The recent strike in the anthracite region caused a drop in production for the week ended Sept. 21, as the total output for that period amounted to only 1,847,000 net tons, a decrease of 241,000 net tons as compared with the week preceding and 159,000 net tons lower than the production during the corresponding week of 1917.

So far as market conditions are concerned, the demand still continues greater than the supply, with a scarcity existing in the domestic sizes of anthracite. The smaller sizes of steam coals are plentiful in the larger cities of the Atlantic seaboard, and some of the producers, it is claimed, are even shading prices in order to dispose of their stocks.

WEEKLY COAL PRODUCTION

Bituminous coal production during the week ended Sept. 21 varied but little from the week preceding and is estimated at 12,650,000 net tons. This output, while 0.4 per cent. below the production during the week of Sept. 14, exceeded production during the corresponding week of 1917 by 2,060,000 net tons, or 19.4 per cent. It will be noted that while the decrease in production during the week ended Sept. 21 was slight, compared with the week preceding, the decrease during the corresponding week of 1917 compared with the week of Sept. 14, 1917, amounted to 387,000 net tons, or 3.6 per cent. thus interrupting for the

second successive week the parallelism of the curve of daily production this year and last maintained during the past three months. The daily average during the current week is estimated at 2,108,000 net tons, slightly lower than the week preceding, but considerably in excess of the daily average (1,765,000 net tons) during the week of Sept. 21, 1917.

The strike in the anthracite fields during the week ended Sept. 21 caused production to decrease 11.3 per cent. The output is estimated at 1,847,000 net tons as compared with 2,088,000 net tons during the week preceding, and as against 2,006,000 net tons during the corresponding week of 1917. The daily average during the current week is estimated at 308,000 net tons, considerably less than the daily average for the coal year to date of 337,000 net tons, which is 2.1 per cent. in excess of the daily average of the same period of last year.

Carriers' reports show increased shipments of bituminous coal during the week ended Sept. 21 from the district including northeast Kentucky, high volatile of southern West Virginia and smokeless fields of West Virginia, Alabama, the district including Illinois, Indiana and Western Kentucky, and the district including Cumberland, Piedmont and Somerset and Fairmont.

Bituminous coal dumped at lake ports, during the week ended Sept. 21, amounted to 1,143,568 net tons, a slight decrease compared with the week preceding. However, compared with the weekly average during July, August and September, the current week's tonnage was 80,000 net tons, or approximately 8 per cent. in excess.

The falling off in shipments to New England during the current week was even greater than the decrease in tidewater shipments, reports from all harbors showing approximately 15 per cent. less coal moving to New England than during the week preceding. Rail receipts also declined 8 per cent., making a total decrease in New England coal, for the current week compared with the week preceding of 12.6 per cent. The decrease in shipments from New York and Philadelphia amounted to 5.7 per cent., from Baltimore 21.1 per cent. and from Hampton Roads 18.4 per cent. Compared with the weekly average for the coal year to date, New England coal receipts, during the current week, fell approximately 36,000 net tons or 6 per cent. Both rail and tidewater figures show a falling off compared with the weekly average, while analysis of tidewater shipments show that New York, Philadelphia and Baltimore exceeded the weekly average, but Hampton Roads fell behind 19,000 net tons or 10 per cent.

Beehive Coke—Beehive coke production in the United States during the week ended Sept. 21 is estimated at 614,000 net tons, 21,000 net tons, or 3.5 per cent. less than production during the week preceding. The daily average during the current year is estimated at 102,000 net tons as against 106,000 net tons during the week of Sept. 14. Operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke during the week of Sept. 21 at 386,640 net tons, and operation of their plants at 76.7 per cent. of their full time, as against 77.8 per cent. during the week preceding. Slightly greater yard labor shortage existed during the current week and as in preceding weeks was the limiting factor.

Byproduct Coke—Operating conditions in the byproduct industry changed but little during the week ended Sept. 21. The plants of the country were operated at 89.2 per cent. of their present capacity as against 89.4 per cent. during the week preceding. A slightly better coal and labor supply existed during the week, while repairs to plants limited production slightly more than during the week preceding. Material improvement occurred during the week in Indiana, Pennsylvania, Tennessee and West Virginia. In Indiana better supply of coal brought about the improvement, in Pennsylvania better labor conditions, in Tennessee repaired plants and in West Virginia other causes. A falling off in production occurred in Alabama, Maryland and Minnesota, and is attributed by the operators in the former state to repairs to plants and in the latter two states to other causes. Increased capacity of Pennsylvania plants is due to starting up more ovens at the Carnegie Steel Co., at Clairton, Penn.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended Aug. 31	Sept. 7	Sept. 14	Sept. 21
Bituminous shipments, 123 roads	223,966	195,367	223,131*	222,874†
Anthracite shipments, 9 roads.	41,281	32,234	40,699	36,859

* Revised from last report. † Subject to revision.

BUSINESS OPINIONS

Dry Goods Economist—Cotton and cotton goods prices continue to hold the attention of the trade. What constitutes a "fair" price for raw cotton now has not yet been disclosed, if, indeed, it has been determined by the committee appointed last week by President Wilson. There has been no change in the wool situation.

Marshall Field & Co.—Current wholesale distribution of dry goods is running well ahead of the heavy shipments for the same period a year ago. The total volume of road sales for immediate and spring delivery is in excess of the same week in 1917. Customers in the market numbered about the same. Collections continue good.

American Wool and Cotton Reporter—A feature not to be overlooked in the wool market is that pressure is being brought to bear in regard to Australian wool. The supply is becoming large and unwieldy, and probably as the shipping situation improves more of such wool will become available to English or American manufacturers. In the minds of the cotton trade the question of price-fixing is naturally uppermost. Prices will be fixed only for the present crop, it is understood, and not for that of another season.

Bradstreet's—Government work expands at the expense of non-essential enterprise, and as goods for ordinary trading tend to become scarcer, buyers in the prosperous crop-yielding zones are anxious to get down orders. In the big eastern centers, however, where taxes, subscriptions to the Liberty bonds, high wages for labor, and the prospective withdrawal of large numbers for militant efforts are factors, buying is conservative. Nothwithstanding all reservations, the flow of business is considerably stronger than the ebb, war work, of course, predominating. Non-essential lines reflect further curtailment, and while buying of holiday gifts has started, the tendency is to eschew luxuries, though here and there new-found wealth has brought about some squandering.

The Iron Age—Price fixing for the fourth quarter, as announced from Washington Tuesday, brought some surprises. Lake Superior iron ore producers asked for 50c. more and were granted 25c., on the ground that the 45c. advance given them three months ago was all absorbed in higher rail freights. Eastern iron ore producers had expectations of sharing in the ore advance, but this was denied them and all other ore producers outside the Lake districts. All basic and foundry iron furnaces get the benefit of a $1 advance. For Tennessee furnaces the advance ranges from $1.25 to $1.75. Virginia furnaces and those in eastern Pennsylvania fare considerably better because of greater distance from the basing points. The general committee of the Iron and Steel Institute has promptly put out new price tables based on the President's proclamation as to pig iron. Differentials on foundry and higher silicon irons are raised; cast iron pipe is put up $5; cut nails and horse shoes are advanced, and various other revisions upward are made.

Atlantic Seaboard

BOSTON

Receipts of bituminous by rail show steady decline. Recent Washington rulings more liberal as to permissible reserves for Class I plants and are being liberally construed. Slackening receipts by water are also the rule. Largely increased requirements for oversea purposes, including naval needs, one of outstanding features. Already there is real anxiety over the advancing season and curtailed shipments. Slow dispatch at Hampton Roads may necessitate releasing additional ships for ocean service. This one of pressing problems. Anthracite shipments sag off. "Storrow anthracite" now coming forward. Difficulties over "allotments" still arise.

Bituminous—From Central Pennsylvania in particular can be noticed a gradual but none the less steady decline in shipments for New England, both all-rail and via the New York piers. Figures for the first three weeks in September show that the reduction all-rail from this one district amounted to more than 25 per cent. Wholesale embargoes placed through recommendation of the different state administrators had a material bearing on this diminished movement, but there has also been evident a large increase in shipments for government use. In addition there has been the case of byproduct plants demanding much heavier deliveries because of new ovens in operation. As an instance of this, two large power plants in Massachusetts chiefly dependent upon coal that has now been requisitioned for byproduct purposes are now relying upon emergency orders to build up a reasonable supply.

The situation as to permissible reserve limits is now much clarified. The Washington ruling of Sept. 13 allows Class I plants to accumulate 105 days supply, and this is so much nearer a reasonable stock limit that consumers on the whole feel much easier. The local fuel authorities are also trying to deal with this subject in a broad-minded way.

Meanwhile, receipts by water have also sloped off to quite an extent. The movement of a considerable volume of coal westward and to line byproduct plants, together with government requirements at the piers, has very much curtailed the flow to Hampton Roads. Detention there only increases, and it is nothing unusual for a steamer to wait five days or even longer for a cargo. The railroads here have had better success lately in accumulating reserves and are fully alive to the wisdom of taking on coal whenever it is available. There is, in fact, a moderate spot demand from the railroads and other large buyers and now that the discharging berths are in better shape, there is no undue delay in handling coal promptly on arrival.

Those who are best informed admit a growing concern for the winter outlook. Without question receipts in New England both by rail and water are going to be cut in drastic fashion. There are rumors of requirements across the Atlantic that exceed any estimates given out, and since those demands will have to be met largely from Hampton Roads, whence comes the largest tonnage for this territory, the subject is one of some interest. Mr. Garfield is on record himself as saying that recent estimates early in the year show that for bunkering purposes alone the increase is 100 per cent. beyond that of last year. We have not yet begun to comprehend the amount of coal that will have to move across the Atlantic between now and spring. More and more ships are coming off the ways and each one adds to the fuel consumed.

A large number of buyers, especially smaller consumers, are still inclined to be fussy about quality and about bunching of cars and the cancellations of requisitions previously on file for administration coal are many and frequent. When shipments have come forward as easily as they have the past two months there is always a sense of security which leads consigners to postpone receiving coal which later they are sure to want.

Out of the movement of wagon coal from Central Pennsylvania there have been some interesting developments. The volume of this coal for New England is much reduced, the high point having been reached when during August about 700 cars were shipped each week to New England consigners. The movement has now dropped to about 350 cars weekly. At the time when the number of box cars was greatest there were many cases of congestion in New England, wagon coal having reached destination at the same time coal was pouring in through regular trade channels, both all-rail and by water. Several serious cases of demurrage resulted and on that point the Railroad Administration has come to the relief of the ultimate consigners by stating that on suitable certification by the fuel authorities a refund will be allowed in case of reforwarded coal, the demurrage to count only from the time delivery is accepted by the party for whose account the car is unloaded.

Anthracite—A further falling-off in shipments of domestic sizes is still noticeable. The "independents" are making no better shipments and the companies are struggling to meet their obligations as pointed out by the anthracite committee. Among the later requisitions is one for 50 cars daily of domestic sizes consigned to Mr. Storrow at the New England gateways. The program is for each retail dealer applying for a share of this coal to send his check in advance to the New England Fuel Administration and bind to accept whatever size is sent him regardless of his preference. In other words, it is considered "anthracite," no distinction being made as to size or grade. It will be interesting to watch the progress of this experiment. The coal has already begun to start forward.

There continue to be difficulties over the "allotments" granted to various communities. Many of these arbitrary estimates are futile because so little heed has been given to local distribution and other conditions understood clearly only by the retail dealers themselves. In consequence towns that are simply unloading ports have been "absolutely embargoed," more attention having been given the size of population than the actual number of tons unloaded during the basic year. Too much in the way of regulation has been attempted and unless some of the bars are taken down there will be a lot of suffering result from the use of a too finely graduated measuring stick.

NEW YORK

Anthracite moving slowly and local dumpings fall behind. Further steps taken to conserve fuel and "lightless night" order to be enforced. Buckwheat sizes plentiful. Shipments to non-essentials result in larger supplies of bituminous. Bunker situation satisfactory.

Anthracite—The situation is moving slowly but surely. Dealers are far from satisfied with the tonnage available, but they are not complaining because they know that consumers are better supplied than they have been under normal conditions in previous years. However, there is a steady demand for the domestic sizes and there is small prospect that this winter will see any surplus on hand. With the month to go three days, dumpings at the local docks for the first 27 days of September were 25,704 cars, as compared with 27,666 cars for the corresponding period of August, a decrease of 1962 cars. This is not encouraging to the trade when it is realized that the early fall months are here.

Part of this decrease is accounted for in the suspension of work by upward of 30,000 mine employees for a few days last month. For the week ending Sept. 27 the dumpings were 6727 cars, a decrease of 69 cars from the previous week, a loss which was principally felt by the local trade inasmuch as New England is receiving most of its coal by rail. On the other hand, production for the week ending Sept. 14 is estimated at 2,088,000 tons, an increase of 29.1 per cent. over the preceding week. Shipments for the week were 40,699 cars, an increase of 8465 cars over the preceding week, but a loss over the shipments of the two previous weeks. The trade is interested in the reports showing increased production and shipments, but are wondering where the coal is being sent.

Shipments of domestic sizes, including pea coal, have been ordered discontinued to 321 communities in this state by the Anthracite Committee, producers and distributors being ordered to concentrate their shipments to other points in the state. This may result in more coal being sent to this market.

With a scarcity of the domestic sizes the reverse exists with respect to buckwheat and smaller coals. There is plenty and more of the smaller coals to go around and some producers have had men out looking for buyers. This is said to be particularly true of independent operators, some of whom, it is also claimed, have been shading prices. In some instances retail dealers, it is claimed, are being asked to take a proportionate share of buckwheat, rice or barley with their orders for the domestic sizes, in order to reduce the stocks of the small coals.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

Circular	Individual	Circular	Individual
Broken..$6.75	$7.50	Buck...$5.10	$5.90
Egg.... 6.65	7.40	Rice.... 4.65	5.10
Stove... 6.90	7.65	Barley.. 4.15	4.30
Chestnut 7.00	7.75	Boiler.. 4.60	
Pea..... 5.50	6.25		

Bituminous—The stopping of deliveries to non-essential industries has put the situation on a better basis so far as supplies of commercial coal goes. There is more coal available for consumers on the preference list, and some shippers were reported to have so much on hand that they are soliciting business. However, when efforts were made to run down these reports they could not be verified. On the other hand, there were shippers who were anxious to locate some available coal. In some circles it was said that producers of gas coal which had been loaded in box cars had disposed of it to outside parties.

The report of dumpings in this harbor fails to show more coal coming here. For the week ending Sept. 27 there were but 7059 cars dumped as against 7277 cars the previous week, a decrease of 218 cars. For the first 27 days of September there were 27,617 cars dumped as compared with 26,908 cars for the first 27 days of August, an increase of 709 cars. For September the average daily dumpings were slightly below the average for the previous two months.

From the mining regions come reports of heavier production and shipments, 36,884 cars having been shipped from the central Pennsylvania fields during the week ending Sept. 14, over the shipments of the previous week, which included Labor Day.

To further save fuel plans are under consideration by State Fuel Administrator Cooke and his associates for consolidating the small electric plants and replacing the less economical isolated plants with central station service. Mercer P. Moseley, chief of conservation for this state, points out that a 100-hp. plant burns 9 lb. of bituminous coal per kilowatt-hour, an average 10,000-hp. plant burns 3 to 4 lb. per kilowatt-hour, and a first class 50,000-hp. plant burns only 2 lb. per kilowatt-hour. He also says that coöperation among electric power companies will save large quantities of coal and increase the profits of operation.

The railroads continue to absorb fuel in good volume. There is a strong call for supplies from points along Long Island Sound, and a decided effort is to be made to take care of the situation before real winter sets in and before transportation difficulties arise. The bunker situation remains practically unchanged. There are plenty of vessels here to take up all the coal available for bunkering purposes but there is no delay in loading.

State Fuel Administrator Cooke has issued an order permitting wholesalers to

add to the purchase price of any coal shipped by water and delivered alongside consumer's docks in New York State, a charge not to exceed 28c. per net ton. This charge shall include insurance, and may be added to the mine price of the coal, plus freight rate to tidewater plus war taxes on freight, plus demurrage at loading points, plus actual boat charges. The order does not apply to coal delivered to retail dealers. The wholesale margin shall include any purchasing agent's commission, or selling agent's commission heretofore authorized by the United States Fuel Administrator, and shall not be in addition thereto. The combined charges or commission of any number of wholesalers or jobbers of a given shipment or shipments of such coal shall not exceed the maximum charge herein allowed for one wholesaler.

Mr. Cooke's order amends an order issued by Ellery B. Gordon, Assistant to the State Fuel Administrator, on June 27, in which he authorized a margin not to exceed 35c. per net ton on coal physically handled by jobbers within the harbor limits of New York State.

Current quotations, based on Government prices at the mines, net ton, f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F. o. b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of-Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite receipts of wanted sizes short. Some accumulation of egg and pea again. Rumors of heavy shipments on the way. Unfavorable labor conditions. Production slightly off. Decision on wages expected daily. Dealers trying to satisfy all customers. Cool weather starts fires. Coal in good preparation. Credit conditions ideal. Steam coal slightly eased. Bituminous in fair volume. Car supply 60 per cent. Current demands cared for.

Anthracite.—Small receipts continue to annoy the retailers, at least the wanted sizes. The consuming public has hardly lost any of its peculiarities as regards the size of coal it wants. It is true that the threatened strike and partial tie-up did induce many of them to take any size that the dealer had in stock. Now that the mining trouble seems to have been temporarily averted the same insistence on stove and chestnut has again cropped up. In the meantime egg and pea are once more accumulating in the yards. The demand for pea coal has been better the last few days, as with the coming of cool weather the humbler class of patrons is calling for it, and in other instances customers who are waiting for stove and nut have been willing to take a ton or so of the small coal to help out.

The labor situation is even more burdensome than ever. Men are scarce and wages high. As a result there is much private bidding for labor, and the changes from one yard to another are a common occurrence. The operators are also reporting that they are growing shorter of help from day to day, despite all restraints which have been placed against the men leaving the mines.

No decision has been rendered as yet by the local fuel administration on the increased margin asked for by some of the retailers, and there is no likelihood that there will be so long as the wage question in the anthracite region is pending. The dealers claim that they are "up against it," as their expenses are slowly creeping up from week to week.

The order from the fuel authorities directing that no further deliveries be made on filling orders which have received two-thirds of their allotment, until Jan. 1, was hardly necessary at all. The retailers are practically a unit in regretting that they followed the committee's suggestion in the spring to fill orders on the two-thirds basis, which was at their option to choose as they thought best. Most of them started in to try to cover all of their orders in this manner and they now find themselves with hundreds of orders on their books without a single pound delivered. Now, with coal burning weather here, they are being sorely pressed to keep these customers satisfied with a ton or two.

With the coming of cool weather the office of the fuel administration was deluged with requests to start furnace fires. These inquiries came from office buildings and schools. In fact so numerous were these requests that the committee was much gratified to learn in this manner the dependence that the people had placed in them. The committee disclaimed direct authority in the matter, but left it up to the individual to decide whether it was necessary to have heat or not. They were warned, however, that they must be careful not to heat buildings at a temperature in excess of 68 deg. The authorities have made it known that they are going to insist on this regulation and in the larger buildings expect to install recording thermometers under seal and will punish any flagrant violations. In the suburban sections the various local fuel committees had ruled that the public heating plants should not turn steam into their mains before Oct. 15, but this week they modified their ruling to the extent of allowing steam to go out but under a reduced pressure.

Inquiry was made lately of the dealers as to the condition of coal reaching their yards; that is, as it related to preparation. In most instances the report was that there was rarely any room for complaint. Of course, there is a considerable tonnage of washery coal coming on the market, and often the dull appearance of much of this product is the cause of complaint from some customers. Even this coal will cause no question if enough fresh-mined coal was received to mix with it. However, the dealers have learned that most of the washery coal is of good quality and have no particular trouble in having their customers accept it. So far as the shipping companies are concerned they practically receive no complaints whatever.

Credit conditions continue ideal and there is really no such a thing as an outstanding account. Many dealers come in the offices and offer spot cash if they can only procure prompt shipment, but of course such tenders are of no avail. The only people who do pay cash in advance these days are the dealers who on searching their records find they have bought a car or so from some shipper in 1916 and no permanent relations having been established, this generally resolves itself into a cash transaction.

Probably there is some slackening of the pressure for steam coals following the easing off of the strike conditions at the mines. At any rate the small domestic demand for buckwheat which sprang up at that time has about vanished, with the exception of those far-sighted dealers who continue to put away a good tonnage of this coal when they can get it. Rice coal is moving fairly well, although small tonnages can occasionally be procured by new customers, most of this going to concerns who, having abandoned the use of culm as a mixture, are having a measure of success with rice. The market for culm can be said to be almost flat, as it appears that every consumer who had the least idea of being able to use it has now given it a trial. No particularly active business is expected in this grade until later in the season.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—Labor and car supply continue to dominate the bituminous trade. Of cars there appears to be an average of a 60 per cent. supply during the last ten days, while labor at no operation is nearly adequate. This condition would show itself more seriously if the car supply should approach 80 per cent. to 90 per cent. Fairly good receipts of coal are reaching the city both from the Pennsylvania and West Virginia zones, although the heavier users are not able to add to their stocks in the volume they did during the summer. It can be said that the industries here are fairly well taken care of for current needs, and most of the anxiety on their part is due to wondering what the future supply will be. It is understood that the wagon mines are being fairly supplied with cars and some brokers in this coal have recently have had fair tonnage for their trade.

BALTIMORE

Demand for cleaner coal spreads, and rejections of box cars are becoming more frequent as supply becomes a little easier. Operators called to discuss condition. Anthracite men in quandary as to short supply and methods of delivery under restricted profit margin.

Bituminous—Supplies of bituminous here continue to get easier as a steady run of fuel keeps up, and a number of big war plants that have supplies a long way ahead are kept out of the market. The heavy proportion of box-car shipments continues, however, and there is a growing tendency on the part of some consumers to refuse to receive the coal in this manner. The box-car coal as a whole not only is less desirable than the coal shipped in open-top cars, but it costs more initially and for unloading. The reduction of heating efficiency by reason of bad coal has spread so seriously from the ordinary business consumers to the preferential fuel supply classes, including railroads, shipyards and steel plants, that the fuel administration has called a meeting for October 3 in Cumberland, Md., of 500 operators of the Somerset, Cumberland, Piedmont and Upper Potomac districts to devise some method of correcting the evil.

There is talk in the trade over the statement that the Government is planning to district coal mines in certain sections and require a minimum production, even if miners have to be shifted from mine to mine to accomplish the result. One of the difficulties of ordinary business is the constantly growing call here of the Government for the best class of coal. Thus the navy has just established a supplemental pool at tidewater to be known as No. 73. Lack of pier labor has presented another problem. First it closed Port Covington and Locust Point piers, leaving Curtis Bay running for coastwise and Government coal, and Canton running for Government coal, as well as harbor and bay points delivery. So much delay was had in loading floats, barges and schooners for ordinary business that it was determined to reopen Port Covington for that purpose. After ten days the order was rescinded and Canton was instructed to get out the business as best it could by working all night shifts.

Anthracite—The situation here is so tight for hard coal that both the dealers and fuel administration officials are fearful that cold weather will find many homes without coal. The local fuel committee has ordered dealers to deliver only one- or two-ton lots. Dealers claim that after supplying part of their trade with two-thirds and having more than 200,000 tons of undelivered orders on their books, much of it since spring, such a plan is not equitable.

Lake Markets

PITTSBURGH

Lake shipments to close of navigation. Byproduct coal scarce. Car supplies fairly satisfactory.

The Pittsburgh district is now regularly shipping in the lake trade from 300,000 to 350,000 tons of coal a week. This is more than its original quota, but on account of meager shipments from some other districts the lake trade not only cannot be taken care of by Oct. 15, the date originally fixed, but can hardly be taken care of up to the close of navigation. R. W. Gardiner, production manager for the district, states that he expects to be required to continue lake shipments as long as the boats can run. Essential industries are being taken care of, as to their current consumption, but are not allowed to stock any coal. Byproduct coal supply is not satisfactory, but the ovens are losing little time, the chief point being that they cannot accumulate the stocks that ought to be provided against the winter. A large quantity of coking coal must be moved to the head of the lakes, and when navigation closes the local situation will be better in that respect.

Coal operators are hopeful that full transportation facilities will be afforded during the winter, but doubt whether the railroads are entirely proof against bad weather. Car supplies in the past week have improved and the situation in this respect is rather satisfactory at the moment.

There is practically no open market activity and prices remain quotable at the set limits: Slack, $2.10; mine-run, $2.35; screen, $2.60, per net ton at mine, Pittsburgh district, with 15c. extra allowed to be charged by brokers.

BUFFALO

Bituminous market quiet. Coal moves more freely on account of more cars. Operators still anxious for greater output. Anthracite by lake good, locally scarce.

Bituminous—The supply seems to keep up, but the issue to shippers of a long list of concerns that are to have no more coal "till further notice" looks ominous. Still it is hoped that this is a further move toward caution and conservation. Besides, in many instances the prohibition is on account of these consumers having an overstock on hand. The shipper sees in it a still further cutting down of his business

and the jobber with no mine connection is in de pair.

A further cause of uneasiness on the part of the jobber is the growing disposition of the consumer to order coal of the government zonal manager and ignore the jobbers entirely. Some jobbers find their business badly cut into from this source alone and all are afraid that taken all together the inroads will put an end to them. The move to allow the railroads to sell coal seems to the jobbers to be a direct effort to put them out of business.

Bituminous prices continue on Government basis, with little or no report now of deviation from them, as follows: Allegheny Valley thin vein, $4.65; Pittsburgh lump, $4.45; Pittsburgh mine run and slack, $4.20; smithing and smokeless, $5.85; cannel, $5.60 to $6.10, all per net ton, f.o.b. Buffalo.

Anthracite—The local shortage continues and is likely to till the lakes close, when it will be easy to fill the local trestles and keep the retailers busy till the cellars are all well stocked. It is hardly expected that the supply will come in fast enough at any time to provide full winter stocks, for Buffalo is too near the mines to make that a necessity, so the complaint of insufficient supply is likely to go on.

The lake trade keeps up well, though there does not seem to be any effort to gain on the shipments of last season. The amount loaded for the week was 114,600 net tons, of which 50,400 tons cleared for Duluth and Superior, 26,900 tons for Chicago, 9500 tons for Fort William, 7300 tons for Sheboygan, 6100 tons for Marouette, 5900 tons for Racine, 3000 tons for Houghton, 2800 tons for Sault and 2700 tons for Hancock.

CLEVELAND

Movement of bituminous to the Northwest is again slackening, and it is now doubtful if September shipments, scheduled for 4,900,000 tons, will much exceed 4,500,000 tons. Car supplies at No. 8 district mines in southern Ohio are reported better, but operators claim local draft boards are calling employees for examinations with no thought of production and in disobedience to General Crowder's instructions. Operations have been much impeded by this.

Bituminous—Production in the No. 8 district of southern Ohio shows a slight improvement over last week, due wholly to a better car supply. Labor is the most disquieting factor, and through no fault of its own. Local draft boards, operators complain, are calling some of the most important men for examination, and in some cases the enforced absence of a handful of men has thrown the entire mine out for the day.

Some railroad fuel continues to come east from Illinois and Indiana, but this is being offset by the shipment of railroad fuel from Ohio mines into Pittsburgh territory. The latest requisition for Ohio rail fuel to be moved east is for 300 cars. Instructions issued by D. F. Hurd, district representative of the Fuel Administration, requiring that orders accepted by operators from jobbers show the final consignee and destination, have been modified to the extent that they do not apply to shipments destined to Canada. The great bulk of Ohio coal continues to go to the lakes, and retail dealers are getting mightly little coal, not more than 15 to 20 per cent. of their requirements, at the most.

City officials of Cleveland have announced they have put away 3000 tons in the municipal coal pile, to be sold in quarter and half-ton lots later. Industrial stock piles continue to melt, and the burden of proof in seeking further supplies is put by operators squarely up to plant officials. The report of the Pittsburgh Vein Operators' Association of Ohio on car supply for the week ended Sept. 21 places the shortage at 13.46 per cent. The railroad rating of members reporting was 8638 cars, and they were supplied 7475. The loss in production, accordingly, is placed at 58,150 tons. Car supply on the Pennsylvania R. R. shows steady improvement. In the week ended Sept. 14 car supply was 15.47 per cent. short, showing an improvement of 2 per cent. The latest report on shipments by association members is for the week ended Sept. 14, when the total carloads was 4969, compared with 4408 carloads the first week preceding and 8876 carloads the second. The movement in the week ended Sept. 14 was 554 cars of railroad fuel, 3011 to the Great Lakes, 1137 to Ohio, 111 to Michigan and Indiana, and 156 to Canada.

Lake Trade—Operators now fear that 4,500,000 tons will be the best they can do for the Northwest in the way of bituminous coal in September. Shipments so far this month hover around the 1,100,000 tons a week mark, those for the week ended Sept. 21 being estimated at 1,095,353 tons, not including vessel fuel. The Great Lakes fleet lost several days early in the week through rough weather on Lake Superior, and the supply at the Lake Erie docks has been somewhat lower than usual. The Northwest is beginning to complain to operators, for with each succeeding week the opportunity of recovering the tonnage lost earlier in the season diminishes. If September falls the expected 400,000 tons behind the Fuel Administration's schedule, the shortage for the lake trade to Oct. 1 will again top the 1,000,000 ton mark.

DETROIT

Jobbers find it difficult to do business under the modified zone regulation. Scarcity of domestic coal continues. Lake shipments are large.

Bituminous—Limitations becoming effective under the recent order of the Federal Fuel Administration, reserving West Virginia coal for use of gas and byproduct plants, railroads and domestic consumers, have placed a new handicap on their business, Detroit jobbers say. The West Virginia mine-run and slack are now being withheld from the industrial consumers that formerly absorbed the greater bulk of this coal coming to the Detroit market. As the territory served by the local jobbers does not include enough railroads, gas works and byproduct plants to constitute an extensive market, the jobbers must place their chief reliance on retailers supplying domestic trade. The retailers are able to handle only a moderate amount of the stock.

The steam plants that have been using West Virginia coal for years are now permitted to purchase only coal from Indiana or from Illinois, which is described as a very unsatisfactory substitute. Some of the industrial plants rather than take chances with coal from the new districts are said to be providing for current needs from reserves they had planned to hold for winter protection.

Anthracite—Detroit's supply of anthracite is still short and is not being increased in a way to reassure the anxious domestic consumers, who are obliged to have recourse to that form of fuel. Shipments arriving this month will scarcely average 1500 tons a day. At that rate of delivery it is calculated nearly 60 days will be required to provide baseburner owners with a start on winter supply.

Lake Trade—Coal is moving over the lake routes in substantial volume and shipments for the month are likely to pass the 4,000,000 ton mark. Growing demands of the grain trade are expected soon to cause a diversion of some carriers that have been available for coal cargoes.

COLUMBUS

The coal trade in Ohio territory continues firm in every respect with the possible exception of screenings, which are coming in rapidly. Domestic and steam tonnage is in strong demand and extra efforts are being made to ship a larger tonnage to the Northwest.

There is still a little softness in screenings, due to the continuation of the embargo against small sizes being shipped into Michigan, which was one of the big markets for that grade. But other steam users, relieved from their limitation on storage, have been gradually absorbing the extra tonnage of screenings and the situation is well in hand.

Domestic trade is now attracting attention of coal men and fuel administrators alike. Dealers have been busy delivering fuel and reports show that fully 65 to 70 per cent. of householders in Columbus and immediate vicinity are provided. Orders are coming in fast, although dealers are not rushed as was the case earlier in the season. Retail prices are firm at former levels. Anthracite as well as Pocahontas is now out of the market entirely. Domestic coke is in good demand. Considerable West Virginia splint is offered as there is a considerable tonnage arriving in this section. The main supply of coal for domestic purposes comes from the Hocking Valley and Pomeroy mines.

The steam trade is rather quiet as reserve stocks are now pretty fair and there is no immediate urgency for shipments.

The lake trade is active and especial efforts are put forth to supply the Northwest as early as possible. As a result lake traffic is being speeded up to a high pitch. Little time is lost in loading and unloading, and the ore movement is good. Car shortage on some of the coal carrying lines is having an effect to reduce the lake tonnage.

Prices on short tons f.o.b. mines are as follows:

	Hocking Thin Vein	Hocking Thick Vein	Pomeroy	Eastern Ohio
Sized grades	$3.00	$2.75	$3.00	$2.60
Mine-run	2.75	2.50	2.75	2.35
Screenings	2.50	2.25	2.50	2.10

CINCINNATI

With a fair car supply, coal movement is well maintained, and some reserves are being accumulated. Proper distribution under priority rules is the chief difficulty of the trade.

With a continuance of cool weather, which has come a trifle early, and the beginning of actual consumption of coal for heating purposes by domestic consumers, hotels, office buildings and others, the season has really begun. Industrial operations also tend naturally to increase in activity and volume as the fall and winter progress, and this also increases coal consumption. The practical application of the priority orders of the Fuel Administration to the distribution of coal is beginning to worry jobbers and operators considerably, especially considered in connection with the operation of the zone system, which has thrown the usual channels of distribution into the discard in favor of the short haul. For instance, there has as yet been very little coal from western Kentucky or Indiana on this market, and that which has arrived has been the cause of considerable dissatisfaction. In the sections close to these fields, where consumers are accustomed to the coal, it is used as a matter of course; but it is much inferior to the fuels from West Virginia and eastern Kentucky to which industrial consumers in and around Cincinnati are accustomed, and as the latter fields are considerably closer to this market than those of Indiana and western Kentucky, the freight rate makes the latter coals cost virtually as much as the better fuel. However, the fact that there is objection to these low-grade fuels indicates in itself that the pressure of actual scarcity has not yet been felt. There may be another story when it is a question of using cheap coal or going without.

LOUISVILLE

Screenings, nut and slack and all steam coals are a little draggy at the present time, while the demand for domestic sizes is somewhat better than it was last week. Domestic coal is scarce on this market, most of the retailers being short of stock.

According to local jobbers, retailers and mine operating concerns, there is a general scarcity of domestic coal this week, with supplies of both eastern and western Kentucky grades scarce. A week ago there was a slight surplus of domestic coal in most of the yards, but this has been cut down by cool weather and a good demand for small lots. Eastern Kentucky screenings are a little draggy, with mine-run fair, while lump is scarce. However, eastern Kentucky coal has been arriving on the local market better than it was.

Under new regulations southeastern Kentucky steam coal is only going into Michigan on permits, while domestic coal is being shipped to that state freely. The mines of the district are being handicapped in disposing of nut and slack under the 30 day provisions, which in the present case should be lifted in order to establish a better market.

Eastern Kentucky has a fair supply of labor and is getting a 60 to 75 per cent. car supply. The larger part of the Blue Gem coal from Kentucky fields is now moving south to the textile districts. Harlan coal is moving to the Lakes and Michigan district. Elkhorn coal is going to the steam and byproducts plants, and Hazard coal is moving to the lakes and almost every district except the south. Western Kentucky coal is moving into Kentucky and Tennessee only. Movement of the latter coal for Kentucky consumption will be considerably reduced when the Federal powder plant at Nashville is running full blast, it being said that about 7000 tons a day will be required there.

Some little Indiana coal is moving into Louisville for use of industries located on the terminals of the Kentucky & Indiana Bridge and Terminal Railroad Co., and retailers are securing some of this coal when unable to secure supplies of western or eastern Kentucky grades. The western Kentucky field is much handicapped at this time on account of shortage of labor, and a 30 to 40 per cent. car supply.

BIRMINGHAM

Steam trade good but easy. Domestic sizes scarce, with strong demand. Car supply fairly good. Labor conditions unchanged.

The trade remains easy as regards steam grades. There are sufficient inquiries and orders in hand to prevent any accumulation at the mines, however, and coal is moving to consumers steadily. The railroads as a whole have a limited supply of fuel in their chutes, and some complaint of shortage came from lines operating in Georgia during the past week.

The domestic market continues to show

great strength and the several days of cool weather the past week boosted the order files of dealers considerably. Receipts are not commensurate with the requirements of the trade, but are as good as or better than the normal record for this season of the year.

The figures of Representative Holmes, of the Fuel Administration, for the week ending Sept. 14, show a production of 385,621 net tons, the lowest weekly output since June. Paydays and registration hampered operations to some extent, while on other days labor worked very irregularly.

Coke

CONNELLSVILLE

Attention to coke quality. More by-product ovens at Clairton. Less foundry and more furnace coke.

Greater stress continues to be laid upon quality of coke than quantity, the testimony of blast furnaces continuing to be that it is quality of coke rather than shortage in supply that is restricting the output of pig iron. The Fuel Administration is inspecting the coke produced at different works in rotation, and through the medium of public meetings is seeking to arouse operators and miners to an appreciation of the importance of producing good coke. The case is put flatly, that the more steel is supplied the more lives of soldiers will be saved, and the better the coke the more pig iron will be made and consequently the more steel.

The output of beehive coke and of raw coal of the Connellsville region shows no material change from week to week. Output is restricted chiefly by mining conditions, car shortage being only occasionally in evidence.

The Carnegie Steel Co. last week put in operation the seventh 64-oven battery of byproduct ovens at the Clairton plant, and the remaining three are expected to be in operation by Nov. 1. The ovens are working on 19-hour coking time, which means 1000 tons of coal per battery per day, the coke yield being about 650 tons. Except for some Pittsburgh district coal furnished by the Fuel Administration occasionally as it can be found, the ovens are operating on high volatile coal from the lower Connellsville region, which accounts for the 65 per cent. yield indicated, the object being to produce as much sulphate of ammonia and toluol as possible. The old basin runs 30 per cent. and less volatile, and coke requirements in the case of Clairton are subsidiary to byproduct requirements.

Offerings of foundry coke in the market are less than formerly, the Fuel Administration having attended to a number of cases of 72-hour coke being offered as foundry grade when it was not urgently needed, and requiring that the coke be furnished to blast furnaces. Essential foundry needs are well taken care of, and the brokers are still able to pick up a carload or so at a time and get a 25c. commission from the operator for disposing of it. Furnace coke scarcely ever reaches the open market, for if any surplus develops the Fuel Administration generally finds it first. The market remains quotable at the set limits; Furnace, $6; foundry, 72-hour selected, $7; crushed, over ¾-in., $7.30; clean screenings from old dumps, over ½-in., $5.50, all per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Sept. 21 at 339,475 tons of coke, a decrease of 8855 tons, and 222,403 tons of coal for shipment, an increase of 6219 tons.

Buffalo—The market is steady, but without recent change. Furnaces are getting what they need by dint of old arrangements and the rather liberal amount of byproduct coke that is produced here. With a third plant, now under construction, the local furnaces ought to be well supplied. Breeze coke is active, most of it selling at government prices, though some cutting of the very fine product is reported. The ore movement keeps up, receipts by lake for the week being 335,550 gross tons. Harry Coulby, chairman of the mobilization committee of Cleveland, has issued a note to vessel owners urging them to keep their craft moving as rapidly as possible, as the ore, coal and grain to be moved yet this fall will require all available tonnage.

Middle Western

GENERAL REVIEW

Operating conditions favorable, with car supply excellent. Higher grade southern Illinois coals, both steam and domestic, remain firm. Coal from other districts selling under Government price.

Operating conditions are continuing favorable to the producers. For the past week the car supply has been excellent; so good, in fact, that a few of the larger coal-carrying railroads have loaned cars to their less fortunate competitors, with the result that practically all the mines in the mid-Western field have been supplied with as many cars as they could load.

Labor appears to be steady, and while there is no great supply of men to draw on, the mines are not closing down through lack of labor. So far as the Middle West is concerned, the labor supply is better than it has been for some time past, and is likely to continue good. There are, however, isolated cases of mines suffering from a man shortage, but these cases are too few and rare to make much real difference in the Mid-West territory, considered as a unit.

As usual, the higher grade coals of southern Illinois remain firm, both in steam and domestic sizes, but practically all other coal from the producing districts of Indiana and Illinois may be purchased under the Government price. This is more especially noticeable in steam, rather than domestic sizes.

In addition, this weak state of the present market will continue just as long as operating conditions prove favorable, or until such time as the Fuel Administration sees fit to enlarge the zone, so that the Illinois and Indiana operators may market their coal outside of the present fixed territory, which is proving not extensive enough to absorb the coal being produced.

CHICAGO

Little interest shown in steam coals, as many plants have sufficient fuel on hand to run from two to three months. Domestic market in better condition.

There has been little interest shown during the past week by the large purchasers of steam coal. Those that buy regularly, on the open market, are placing their orders as usual, only at a substantial reduction from the Government price.

To size up the situation, the coal-buying public is not much interested in coal just now. There are a number of reasons for this, chief among which is the fact that the average steam plant has sufficient coal in storage to run from eight to twelve weeks.

The domestic market is in somewhat better condition. The recent rule of the State Fuel Administration, that no anthracite be burned until Christmas, has forced a number of householders, who had already been fortunate enough to get hard coal, into the market to purchase some bituminous.

MILWAUKEE

Rumor that all Lake Michigan coal-receiving ports will soon be embargoed. Shortage of labor seriously hampering deliveries.

Lake receipts of coal are slacking up some, and a rumor is afloat that all Lake Michigan ports will soon be wholly or partly embargoed. Vessel masters who bring the story from the lower lake docks are inclined to credit it. The Reiss Coal Co., which maintains docks at Waukegan, Ill., and other lake ports, has been directed by the Government to cease taking in coal at Waukegan. As the naval station at Great Lakes, near by, relies upon the Waukegan supply for kitchens and hospitals, and as scores of homes are without fuel, the people in these places are naturally greatly disturbed over the order.

State Fuel Administrator Fitzgerald considers the coal outlook for the winter in this district favorable. He says not quite as much anthracite is on the docks as at this time last year, but the amount of bituminous in stock is greater. However, if the lake supply should be curtailed or cut off altogether, there would be a different aspect to the situation.

Receipts of coal by lake at Milwaukee thus far in September include 171,700 tons of anthracite and 160,600 tons of bituminous, making the season's receipts of hard coal up to the time of this report 443,905 tons, and of soft coal 2,655,532 tons.

Hard coal is being dealt out sparingly to the smaller dealers in Milwaukee, and as a consequence many homes still remain unsupplied. If this condition of things does not change soon many consumers will have to substitute soft coal or go without fuel. A shortage of labor is also hampering deliveries. One firm alone recently purchased 20 trucks, half of which are still awaiting their first loads.

West Allis, a suburb of Milwaukee, has only a small portion of 30,000 tons necessary to tide homes and factories over the winter, and the authorities and factory proprietors have petitioned the Government for relief. Some of the factories are engaged in war work.

The city authorities will sell coal to needy people during the coming winter at cost. The distribution will be made from the various fire engine houses and ward lots.

Fire is raging in the City Fuel Co.'s yard at Manistique, Mich., in the Green Bay district, and many tons of coal have already been destroyed.

ST. LOUIS

A quiet, easy market as far as demand is concerned, with a surplus of all sizes excepting Carterville grades. Production not heavy. Cars are plentiful and transportation good. Demand seems to ease up everywhere locally.

The St. Louis market continues easy. There is no demand for anything but the Carterville grades. This is especially noticeable in domestic. The retail demand for coal has fallen off to a remarkable extent in the last ten days and a survey of the retail situation develops the fact that dealers have enough orders on their books now for from one to two weeks ahead and the bulk of this business is for Carterville coal, which cannot be secured. As a rule there is not more than a couple of days supply of orders for Standard and Mt. Olive on hand.

The domestic demand in the country is in somewhat the same condition. Plenty of Carterville orders and no Carterville coal, and a reasonably good supply of Standard and Mt. Olive coal but no orders for those grades. With the first touch of real cold weather, however, business will develop on these coals. The weather here for the past two weeks has been unusually cool for this period, but not sufficiently so to develop any business.

On steam coals the conditions are reversed. There is no demand for Carterville steam coals, as these find a ready market in the north.

The demand for the Standard and Mt. Olive steam sizes, however, is very weak, and it is being continually limited. The price of screenings is far below the Government maximum, and in a manner, this has retarded the development of a big tonnage and caused the forcing of the market on these sizes.

There still continues to be a surplus of coal in both the Mt. Olive and Standard fields, with no available market. This does not refer to steam sizes only, as there is a large tonnage of domestic sizes unbilled nearly every day.

The car supply has been better throughout the Standard field the past week and transportation shows up fairly well, but the tonnage is not increased on account of county fairs, which seem to be hitting southern Illinois generally at this particular time. In the Mt. Olive district car supply is better than usual and this field continues to have considerable time placing their tonnage.

In the Carterville and Duquoin fields some improvement has been noted the past week, but not to any great extent. Car shortage continues in this field and transportation has shown little improvement. The railroad tonnage from this field still continues large, and little of the coal moves into this territory. After the first of the month a better tonnage is expected to come along.

The railroad tonnage throughout the Mt. Olive and Standard field still continues good, and were it not for the railroad coal that is moving these mines would be working only half of the time on account of no market in which to place their coal. It is figured at the present time that over 85 per cent. of the coal that is usually in by Dec. 1, is now stored in the homes in St. Louis, and the tonnage may be greater than that.

There are no eastern coals coming in. A small tonnage of Arkansas anthracite and semi-anthracite comes in when loaded in equipment that must come this way. Coke is getting scarce and very little to offer for carload shipments.

The prevailing market per net ton f.o.b. mines is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump..	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg..	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut.	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1.....	3.05@3.20	3.05@3.20	.....
No. 2.....	3.05@3.20	3.05@3.20	.....
No. 3.....	3.05@3.20	3.05@3.20	.....
Mine Run..	2.35@2.50	2.35@2.50	2.20@2.30
Screenings..	2.17@2.32	2.17@2.32	1.50@1.60

Special preparation on Carterville is 10 cents extra.
Williamson & Franklin Co. rate is $1.10.
Other fields 95 cents.

Bessemer iron *	36.60	36.60	55.95
Basic iron *	32.00	32.00	53.00

* These prices include the freight charge from the valley to the Pittsburgh district. † Delivered Tidewater, New York.

STRUCTURAL MATERIAL—The following are the base prices, f.o.b. mill, Pittsburgh, together with the quotations per 100 lb. from warehouses at the places named:

	Mill, Pittsburgh	New York Current	New York One Year Ago	St. Louis	Chicago
Beams, 3 to 15 in.	$3.00	$4.245	$5.25	$4.27	$4.27
Channels, 3 to 15 in.	3.00	4.245	5.25	4.27	4.27
Angles, 3 to 6 in., ¼ in. thick	3.00	4.245	5.25	4.27	4.27
Tees, 3 in. and larger	3.05	4.245	5.30	4.27	4.27
Plates	3.225	4.745	9.00	4.52	4.52

BAR IRON—Prices in cents per pound at cities named are as follows:

Pittsburgh	St. Louis	Denver	Birmingham
3.50	4.24	4.85	4.475

NAILS—Prices per keg from warehouse in cities named:

	Mill Pittsburgh	St. Louis	Denver	Chicago	Birmingham	San Francisco	Dallas
Wire	$3.50	$4.50	$5.05	$4.32	$4.75	$5.95	$4.75
Cut	4.00	5.50	.....	4.47	....	6.40	.....

TRACK SUPPLIES—The following prices are base per 100 lb. f.o.b. Pittsburgh for carload lots, together with the warehouse prices at the places named:

	Pittsburgh	Cincinnati	Chicago	St. Louis	San Francisco	Birmingham	Denver
Standard railroad spikes ⅝-in. and larger	$3.90	$6.00	$4.50	$5.30	$6.70	$6.00	$5.30
Track bolts	4.90	8.90	5.50	Prem.	8.00	8.00	6.30
Standard section angle bars	3.25	....	4.45	Prem.	5.15	....	4.85

COLD DRAWN STEEL SHAFTING—From warehouse to consumers requiring fair-sized lots, the following discounts hold:

Cincinnati	Cleveland	Chicago	St. Louis	Denver	Birmingham
17½%	List	+10%	+15%	+40%	+30%

HORSE AND MULE SHOES—Warehouse prices per 100 lb. in cities named:

	Mill Pittsburgh	Cincinnati	Chicago	St. Louis	Denver	Birmingham
Straight	$5.75	$7.00	$6.50	$6.25	$8.00	$7.25
Assorted	5.90	7.00	6.50–7.00	6.40	8.25	7.50

Cincinnati—Horseshoe nails sell for $4.50 to $5 per 25-lb. box

CAST-IRON PIPE—The following are prices per net ton for carload lots:

	New York Current	New York 1-Month Ago	New York One Year Ago	Chicago	St. Louis	San Francisco
4 in.	$64.35	$64.35	$68.50	$64.80	$63.00	$80.50
6 in. and over	61.35	61.35	65.50	61.80	60.00	77.50

Gas pipe and 16-ft. lengths are $1 per ton extra.

STEEL RAILS—The following quotations are per ton f.o.b. Pittsburgh and Chicago for carload or larger lots. For less than carload lots 5c. per 100 lb. is charged extra:

	Pittsburgh Current	Pittsburgh One Year Ago	Chicago Current	Chicago One Year Ago
Standard Bessemer rails	$57.00	$38.00	$67.00	$38.00
Standard openhearth rails	55.00	40.00	65.00	40.00
Light rails, 8 to 10 lb.	*3.135 (100 lb.)	83.00	*3.135 (100 lb.)	68.00
Light rails, 12 to 14 lb.	*3.09 (100 lb.)	82.00	*3.09 (100 lb.)	67.00
Light rails, 25 to 45 lb.	*3.00 (100 lb.)	75.00	*3.00 (100 lb.)	65.00

* Government price per 100 lb.

OLD MATERIAL—The prices following are per gross ton paid to dealers and producers in New York. In Chicago and St. Louis the quotations are per net ton and cover delivery at the buyer's works, including freight transfer charges:

	New York	Chicago	St. Louis
No. 1 railroad wrought	$30.80	$31.00	$34.00
Stove plate	26.50	25.00	19.00
No. 1 machinery cast	34.00	29.50	21.50
Machine shop turnings	16.25	17.00	19.00
Cast borings	16.25	17.10	18.50
Railroad malleable cast	31.20	29.00	25.50

COAL BIT STEEL—Warehouse price per pound is as follows:

New York	Cincinnati	Birmingham	St. Louis	Denver
$0.12	$0.16½	$0.18	$0.19	$0.17½

DRILL STEEL—Warehouse price per pound:

	New York	St. Louis	Birmingham
Solid	16c.	16c.	15c.
Hollow	24c.	....	....

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh; basing card of Nov. 6, 1917, for steel pipe and for iron pipe:

BUTT WELD

Steel Inches	Steel Black	Steel Galvanized	Iron Inches	Iron Black	Iron Galvanized
⅛, ¼ and ⅜	44%	17%	⅜ to 1½	33%	17%
½	48%	33½%

	Medium Grade	Heavy Grade
St. Louis	28%	35%
Denver	35–5%	30%
Birmingham	35%	35%
Chicago	45%	40%
Cincinnati	40–10%	40%

RAWHIDE LACING—35% off list.

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$0.99
Asbestos for high-pressure steam	1.76
Duck and rubber for piston packing	1.10
Flax, regular	.99
Flax, waterproofed	1.21
Compressed asbestos sheet	1.10
Wire insertion asbestos sheet	1.30
Rubber sheet	.66
Rubber sheet, wire insertion	.99
Rubber sheet, duck insertion	.55
Rubber sheet, cloth insertion	.25
Asbestos packing, twisted or braided, and graphited, for valve stems and stuffing boxes	1.21
Asbestos wick, ½- and 1-lb. balls	.75

WIRE ROPE—Discounts from list price on regular grades of bright and galvanized are as follows:

	New York and St. Louis
Galvanized iron rigging	+20%
Galvanized cast steel rigging	List
Bright plain rigging	30%
Bright cast steel	17½%
Bright iron and iron tiller	5%

MANILA ROPE—For rope smaller than ⅜-in. the price is ½ to 2c. extra; while for quantities amounting to less than 600 ft. there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: ⅛-in., 8 ft.; ¾-in., 6; ⅞-in., 4½; 1 in., 3½; 1⅛-in., 2 ft. 10 in.; 1¼-in., 2 ft. 4 in. Following is price per pound for ⅛-in. and larger, in 1200-ft. coils:

Boston	$0.33½	Birmingham	$0.39
New York	.36	Denver	.35½
Cincinnati	.33½	Kansas City	.34
Chicago	.34	Seattle	.34
St. Paul	.34	St. Louis	.33
San Francisco	.32	Los Angeles	.35

PIPE AND BOILER COVERING—Below are discounts and part of standard lists:

PIPE COVERING

Pipe Size	Standard List Per Lin. Ft.

FREIGHT RATES—On finished steel products in the Pittsburgh district including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates per 100 lb. are effective:

Boston	$0.27	New Orleans	$0.385
Buffalo	.17	New York	.245
Chicago	.27	Philadelphia	.23
Cincinnati	.23	St. Louis	.34
Cleveland	.17	St. Paul	.495
Denver	.99	Pacific Coast (all rail)	1.25
Kansas City	.59		

Note—Add 3% transportation tax.

COAL AGE

Volume 14 New York, October 10, 1918 Number 15

Hun Propaganda

By Floyd W. Parsons

Recently the *New York Evening World* launched a virulent attack on the coal industry and the United States Fuel Administration. The articles, featured on the front page and written by a woman unfamiliar with coal mining, attempted to deal with subjects that have occupied the attention of experienced mining engineers for many years.

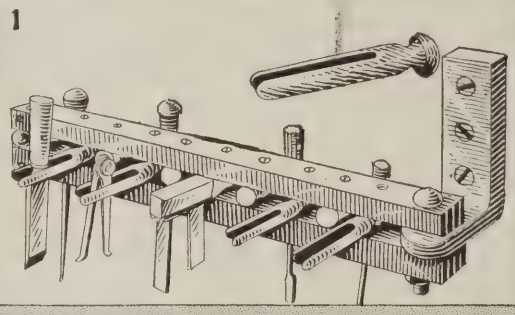
The campaign was disloyal and malicious. Not only were the articles filled with inaccuracies, but the whole attack was based on a false premise. The chief effort of the paper was to convince the public that utilization of the culm banks in the anthracite field offered a solution to the coal problem in New York.

Evidently no effort was made to discover the true facts in the situation. If the *Evening World* had desired to be fair, it could easily have learned that anthracite culm cannot be burned in the average furnace unless it is first mixed with from one to two times the same quantity of bituminous coal. It could have found on slight investigation that months are required to change the common style of furnace to burn these low-grade mixtures of fine coal. And it certainly knows that even if such a change were advisable, the necessary equipment could not now be obtained.

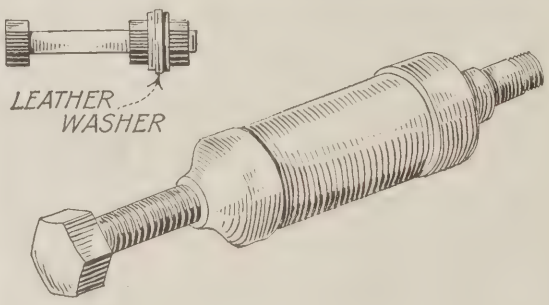
It would have been easy for the author of the articles to have procured correct information from Dr. Garfield, for he has detailed reports on the entire culm situation made by responsible and independent Government officials months ago. The contents of these reports would have been available to anyone seeking to tell the truth. But the paper desired to appear in the rôle of one discovering a great idea, whereas the story is ancient to everyone who knows anything about fuel.

The *Evening World* has stooped to the lowest form of yellow journalism. The efforts of mining men to call the attention of the editors of the newspaper to the mistakes in the articles were met with insolence. Carefully prepared statements sent them were ignored. And still this paper boasts its loyalty, while at the same time it walks hand-in-hand with a writer who refuses facts and advocates a plan that would cause untold suffering if followed.

Last winter the whole nation cried out against the shipment of dirty coal. Now we have among us a paper that advocates the use of our railroad cars to transport a product that is 50 per cent. rock. The hard-coal operators are charged with being conspirators because they insist on loading only the cleanest kind of coal in every car they can get. Dr. Garfield has an active department in his organization that is charged with seeing that no shipments of fuel are made which contain an undue percentage of ash.



The *Evening World* wants all of this set aside. It demands that miners be taken from the chambers in the mines where they are producing real fuel and be employed in shoveling and hauling a waste product that won't burn until it is washed and mixed with true coal. It demands that the small mine cars, already too scarce, be set to hauling this mine waste, and that power, and time and material be employed in such service instead of being utilized effectively in actual mining operations.



When an organ such as the *Evening World* seeks to be sensational through the perversion of facts in times of peace, it deserves to lose the respect of decent people. But in these days of great trial, when the sons of our miners, mine managers and fuel administrators are shedding their blood and doing their full share in France, the paper that willingly lends itself to the selfish interests of a few disgruntled culm-bank profiteers is consciously or unconsciously rendering direct service to the evil master of the Huns. The editors who print such vicious propaganda without careful investigation are no better friends of the cause of Liberty than the paid soldiers of the Emperor of Germany.

IDEAS AND SUGGESTIONS

1. Clothespins are useful as tool rack.
2. Homemade spacious grease cup.
3. Pipe fitting simplifies shaft leveling.
4. Unique valve seat remover.

Raising Steam With the Waste Products of Yesterday

Silt, Formerly Considered a Nuisance, As It Meant a Disposal Problem to the Operator and Pollution to the Streams of the Farmer, Is Today a Valuable Asset—Burned on a Special Grate It Supplants More Essential Fuel

THE old culm banks in the anthracite region are fast disappearing. The washery is redoubling its efforts, and the products from this method of preparation tend in large measure to force anthracite shipments above previous records. Up to within a quarter of a century ago, the culm banks rapidly increased in size; but since that time a movement to utilize this waste has steadily gained favor, and within a short time these old landmarks likely will have completely disappeared.

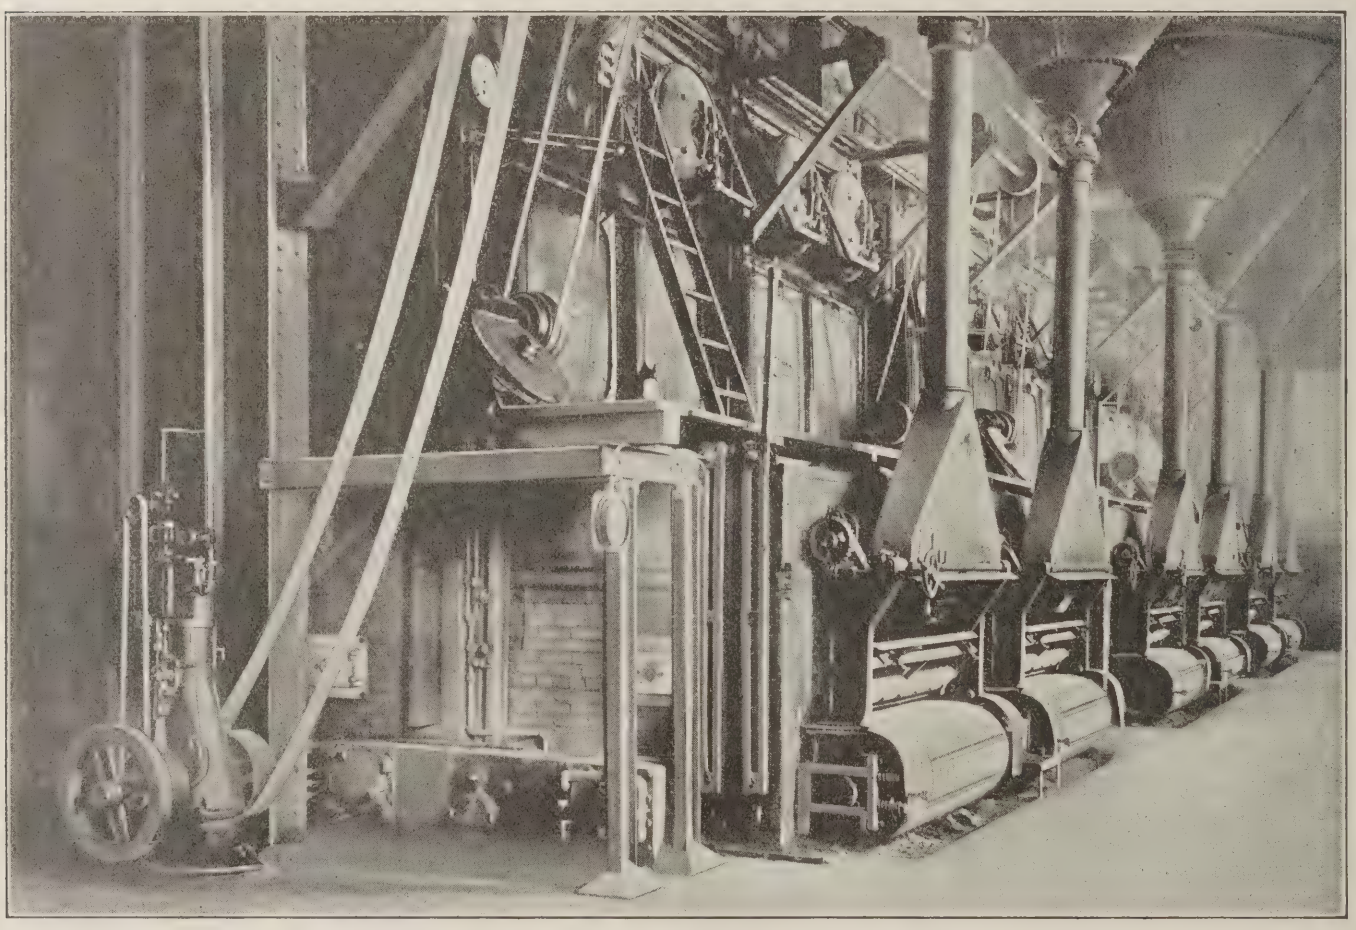

FIG. 1. FRONT VIEW OF BOILER PLANT AND COXE STOKER INSTALLATION

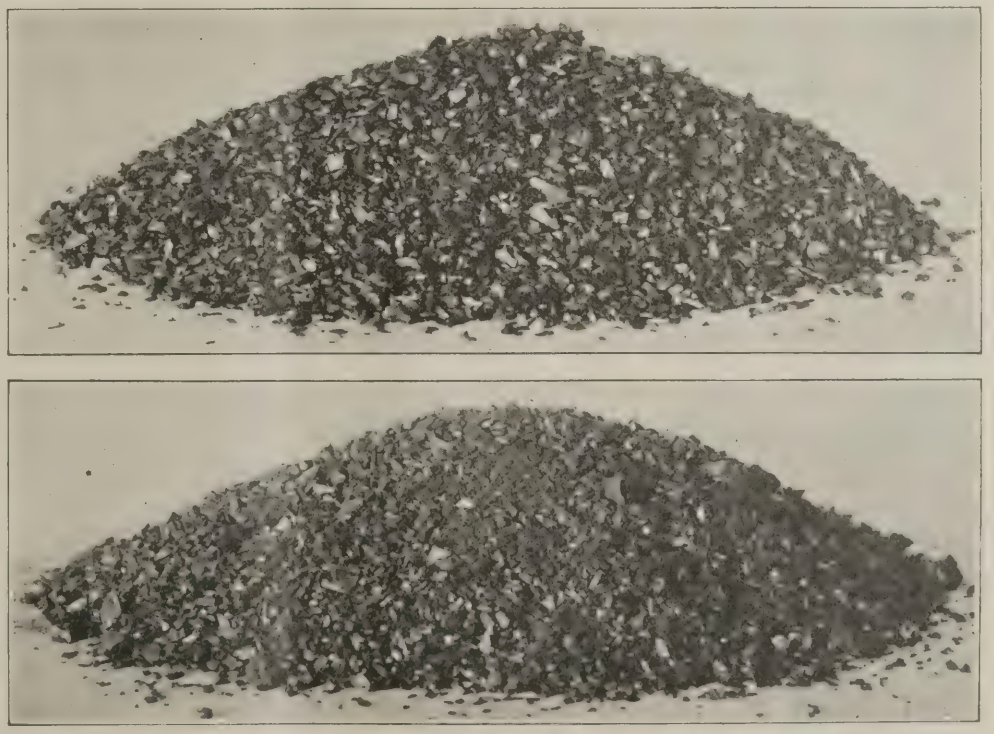
The first practical steps looking toward utilization of the small sizes of anthracite were taken about February, 1890, when a commission was appointed according to an act of the legislature of Pennsylvania. It was the purpose of this commission to investigate the waste of coal mining, with a view to the utilization of such waste. The results of this investigation were reported in May, 1893.

An active member of this commission was the late Eckley B. Coxe, probably the leading mining engineer of his time. Mr. Coxe was the most prominent figure in the management of Coxe Brothers & Co.'s extensive anthracite interests in the Hazelton region of Pennsylvania. He was especially well equipped by temperament, training and facilities at his command to attain results along the lines noted.

Mr. Coxe's study of the subject led him to select as the most important of all the practicable measures of economy, the utilization of the smallest sizes of coal, such as had been permitted for many years to go to waste. With the aid of his assistant, John R. Wagner, a series of experiments was begun by Mr. Coxe upon the burning of small anthracites. The results of these investigations were published in the "Transactions" of the American Institute of Mining Engineers,[1] from which the following is quoted: "Having determined in a general way what seemed to me the proper conditions for

[1]Vol. 22, p. 581.—A paper entitled, "A Furnace with Automatic Stoker, Traveling Grate and Variable Blast Intended Especially for Burning Small Anthracite Coal," by Eckley B. Coxe.



FIGS. 2 AND 3. NATURAL SIZE BOILER FUEL
Fig. 2 (Top)—No. 2 buckwheat (or rice). Fig. 3 (Bottom)—No. 3 buckwheat (or barley)

burning small anthracite economically, I [E. B. Coxe] started to design a furnace which would, as far as possible, fulfill the required conditions, which were: (1) To ignite the coal and burn it up without mixing it with fresh fuel; that is, that fresh fuel would not be added to the already partially consumed coal. (2) To have the furnace so arranged that the combustion would be continuous and uniform; that is to say, that when the furnace was in use the condition of the fire would be practically the same at any hour of any day of any week of the year. (3) To make the work of firing as easy as possible, so that a minimum number of firemen would be employed and that the whole operation of the furnace would be controlled by an intelligent man who would have more use for his brains than for his muscles; the idea being that in a large and complete plant the coal would be brought from the source of supply by elevators or drags and be fed to the furnace without hand labor, and that the ashes would be dumped into a pocket where they could be easily loaded into cars in the same way. No pokers, slice bars or other similar tools should be needed."

In order to meet the foregoing conditions, Mr. Coxe designed and built the first Coxe traveling grate and mechanical stoking furnace, and in 1893 he completely equipped his Oneida colliery with this device. It is stated that the original stokers are still in constant operation in connection with Stirling boilers. It is interesting to note the results of a test made at the completion of this boiler plant. In a continuous test extending over a period of one week, an evaporation of 8.6 lb. of water from and at 212 deg. F. per pound of dry coal was made at 4.2 per cent. over the rated capacity of the boilers. The coal burned was No. 2 buckwheat (rice) containing 5.45 per cent. volatile, 15.5 per cent. ash and 76.95 per cent. fixed carbon.

Unfortunately for the mining industry, Mr. Coxe died in May, 1895. As he had been the designer of the grate bearing his name, and the prime mover in its development, with his death his improvements automatically ceased. In 1903 the holdings of Coxe Brothers & Co., which included the Drifton shops, were taken over by the Lehigh Valley Coal Company.

A brief review of the steps leading to the working out of a practical furnace for burning small anthracite coal is not only interesting but essential to a proper understanding of the situation. The Coxe traveling grate, as first used, would burn efficiently No. 1 buckwheat and rice (previous to 1893 these sizes were considered waste products), but it was not designed to

FIGS. 4 AND 5. NATURAL SIZE SMALLER BUCKWHEATS
Fig. 4 (Top)—No. 4 buckwheat (or bird's-eye). Fig. 5 (Bottom)—Mixture, mostly silt with small amount of No. 4 buckwheat. Fuel used by Delaware, Lackawanna & Western Co. and the Lehigh Coal and Navigation Co. on Coxe stokers

burn economically and at high ratings a coal as small as No. 4 buckwheat. In order to burn this latter size of fuel economically, and at a high rate of combustion, William Lloyd, formerly superintendent of shops for the Lehigh Valley Coal Co., redesigned the stoker.

The Coxe traveling grate now entered upon a different phase of its career. It would be extremely interesting to follow the experimental work of Mr. Lloyd as he perfected his plan for the modified Coxe stoker. It became apparent at an early stage of his experiments to burn the smaller buckwheats that each particle of these fuels was so light in weight that it was necessary to use a modified grate. In order to keep the forced draft from blowing the unburned fuel from the grate surface, a grate was designed which would permit the distribution of air beneath and through the fuel bed in sufficient volume to generate a high as well as an economical rate of combustion. Mr. Lloyd changed the air compartments with their controls in the grate in such a way that it is now possible to introduce forced draft beneath any part of the entire grate surface without appreciably affecting the fuel bed on the remainder of the grate surface.

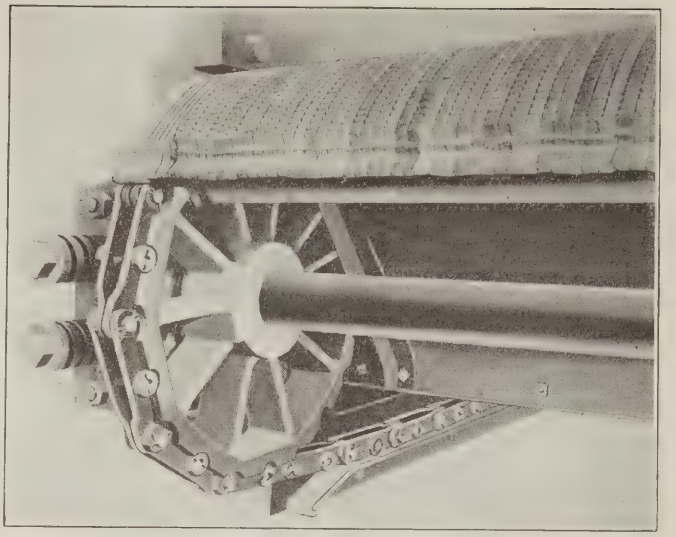


FIG. 6. DETAILS OF KEY ON CARRIER BAR; ALSO CHAIN AND SPROCKET WHEEL

Mr. Lloyd designed a "key," or grate finger, which distributes the air from beneath and through the fuel bed in a most satisfactory manner. The present standard key is a casting 8 in. in length by $\frac{3}{4}$ in. in width, having along one side 15 bosses (grooves) $\frac{3}{32}$ in. deep and $\frac{3}{16}$ in. wide. Across the top of the key are other grooves, $\frac{3}{32}$ in. wide and $\frac{1}{8}$ in. deep, 15 in number on one key with 16 on the keys in contact with it on either side. This staggered arrangement of the top surface grooves of the keys is shown in Fig. 7. A larger detail of the keys is given in Fig. 6. The object of the grooves is to make of the entire grate surface a series of channels which, when the forced draft is applied beneath the grate, subject the fuel bed to a "blanket" of air in large volume but with low velocity at any given point. Because of this uniform air distribution and control it is possible to operate the stokers at a high rate of combustion and high percentages of efficiency and economy.

Considering some of the mechanical features of the Coxe grate, it can readily be seen that the key is one of the important details. In fact, it is the essential feature of the stoker. These keys are arranged on carrier bars, which hold them in place, and are readily moved along the length of the bar in building up the grate. In practice, when keys give out at any time they are readily replaced on the end of the carrier bar, one at a time. The carrier bars extend from chain to chain, the latter being placed one on either side of the grate; the chains run over sprocket wheels and are driven from the end of the grate at the point where the ash is discharged, which is opposite the end where the coal is fed to the furnace. The arrangement of the keys on the carrier bar is shown in Fig. 6, as is also the carrying chain running over the sprocket wheel at one side of the grate.

The assembled grate, practically installed under a water-tube boiler, is shown in Fig. 7, which is a view from the inside end of the grate. The coal-feeding arrangement is shown in place at the other end of the stoker. The chain and double worm gear reduction is shown in duplicate at the left of Fig. 7; the left-hand feed is attached to a completed installation bricked in and ready to operate. The pit for receiving the ash from one of the stokers is hidden from view by the platform used by the workmen installing the furnace. A longitudinal sectional view of a stoker under a Babcock & Wilcox boiler is given in Fig. 8; the method of removing the ashes is also shown. A number of different plans are used in ash removal—by conveyor or scraper lines, by ash cars or by other mechanical means. Hand labor is done away with entirely, or is simplified in modern plants. A simple coal-handling apparatus is shown in the leading illustration; here coal is taken from the conical overhead hoppers to the distributing hoppers at the outside end of the grate by means of pipes.

The present method of draft control on a modern Coxe stoker is the result of years of experimentation. The air space in the grate is from 5 to 7 per cent. of the total grate surface. There is no large volume of air coming through the grate at any one point. Under the grate the air space is so partitioned that the proper amount of air is furnished to each part as needed. Thus the green-coal end of the stoker receives the most draft, and the air volume is steadily reduced until practically no air is supplied at the end where the coal is completely burned.

Turning from structural details to some practical illustration, a striking object lesson is presented at the Coadale plant of the Lehigh Coal and Navigation Co. Here there is a 750-hp. Stirling boiler unit equipped with two Coxe stokers, on which is burned a mixture which is practically silt with some No. 4 buckwheat in it. Two firemen are in attendance during 24 hours of service; one man on each 12-hour shift. Adjoining the Stirling boilers is a hand-fired boiler plant, with a total rating of 2348 hp., which is using rice and barley for fuel. At this latter installation a typical scene was being enacted at the time of the writer's visit to the plant. Eleven firemen were required every 24 hours to keep steam up. The men in attendance were engaged in cleaning fires, shoveling on coal and removing ashes —duties handled mechanically at the stoker installation. The opinion was expressed by the men in charge that the boilers being fired by the Coxe stokers at 200 to

230 per cent. above their rating were delivering more steam than all the hand-fired boilers put together. On the latter an efficiency of 68 to 75 per cent. of rating was maintained. The reason for this might not be so obscure when the difference between the two methods is analyzed. At the hand-fired plant, at one battery of boilers the furnace doors were swung wide open under one boiler while a fireman laboriously cleaned the fire, scraped out the clinkers and then shoveled on the coal so as to almost bank the fire. This condition existed at one end of the battery, while at the other end a fire which had been similarly treated some time ago was just coming to life and active service again. The two intermediate fires were keeping up steam in the four boilers of the battery. A similar unit adjoining made up the other half of the hand-fired boilers.

In the house containing the Stirling Coxe stoker outfit, the solitary fireman in charge was occupied in regulating the speed of the traveling grate and the amount of the draft and coal fed to the furnace. Occasionally he looked after the ash disposal. Normally, on opening the side doors in the brickwork inclosing the boilers and furnace the fire can be seen burning steadily at any hour of day or night; sometimes the flame comes out of these doors when the draft is increased somewhat, but the fuel bed on the grate varies little. The following are a few of the reasons given for being able to obtain high ratings and efficiency with the Coxe traveling grate with a minimum amount of labor:

The fuel bed is always thin, never more than 4 to 5 in. in thickness, thus allowing sufficient air to pass through the bed of burning coal for nearly perfect combustion with a minimum amount of resistance. The fires are cleaned automatically; the fuel is ignited as it enters the furnace, gradually burns down as the grate slowly moves toward the bridge wall, and the burned-out fuel (ash) is discharged into the pit. The forced-draft control and distribution is such that the air can be placed under the grate exactly and only where the fuel requires it for proper combustion, thus eliminating any excess. The speed of the stoker and draft regulation are so simply and easily controlled that unskilled labor can operate the stoker efficiently and at high ratings. Because of the simplicity of its operation one man can attend to a number of stokers.

TABLE I. OPERATING RESULTS OF ANTHRACITE BUCKWHEATS*

750-Hp. Boiler—Coxe Traveling Grate—Average Steam Pressure 125 Lb.	No. 1 Buckwheat	No. 2 Buckwheat	No. 3 Buckwheat	No. 4 Buckwheat	Uncleaned Buckwheat
Average horsepower of test	1,500	1,395	1,200	1,010	495
Maximum horsepower of test	1,750	1,600	1,400	1,100	650
Average per cent. rating	200	186	160	134	66
B.t.u. per pound dry coal	12,250	12,000	11,500	11,000	10,000
Combined efficiency of boiler, furnace and grate, per cent	74	70	65	61	45
Equivalent evaporation from and at 212 deg. F. per pound of dry coal, lb	9.35	8.77	7.7	6.9	4.6
Dry coal consumed per horsepower per hour, lb	3.69	3.93	4.48	5.00	7.5
Dry coal per square foot of grate surface per hour, lb	25	25	25	25	25
Boiler horsepower per square foot of grate surface	6.8	6.36	5.5	4.9	3.3
Grate travel in feet per hour	16.6	16.5	16.2	15.2	11.1
Cost per horsepower per hour in cents	0.87	0.58	0.43	0.27	0.21

NOTE—Last figures correspond to prices at the mines and have to be adjusted to meet the various freight rates.

*Table by William P. Frey, Fuel Engineer, Lehigh Coal & Navigation Co., Lansford, Penn. Published in Fuel Supplement (July, 1918), Vol. 40, No. 7, of Journal of American Society of Mechanical Engineers.

The Lehigh Coal and Navigation Co. has passed the experimental stage as regards the use of Coxe stokers and is equipping other boilers with this type of furnace. The results being obtained by this company on the Coxe

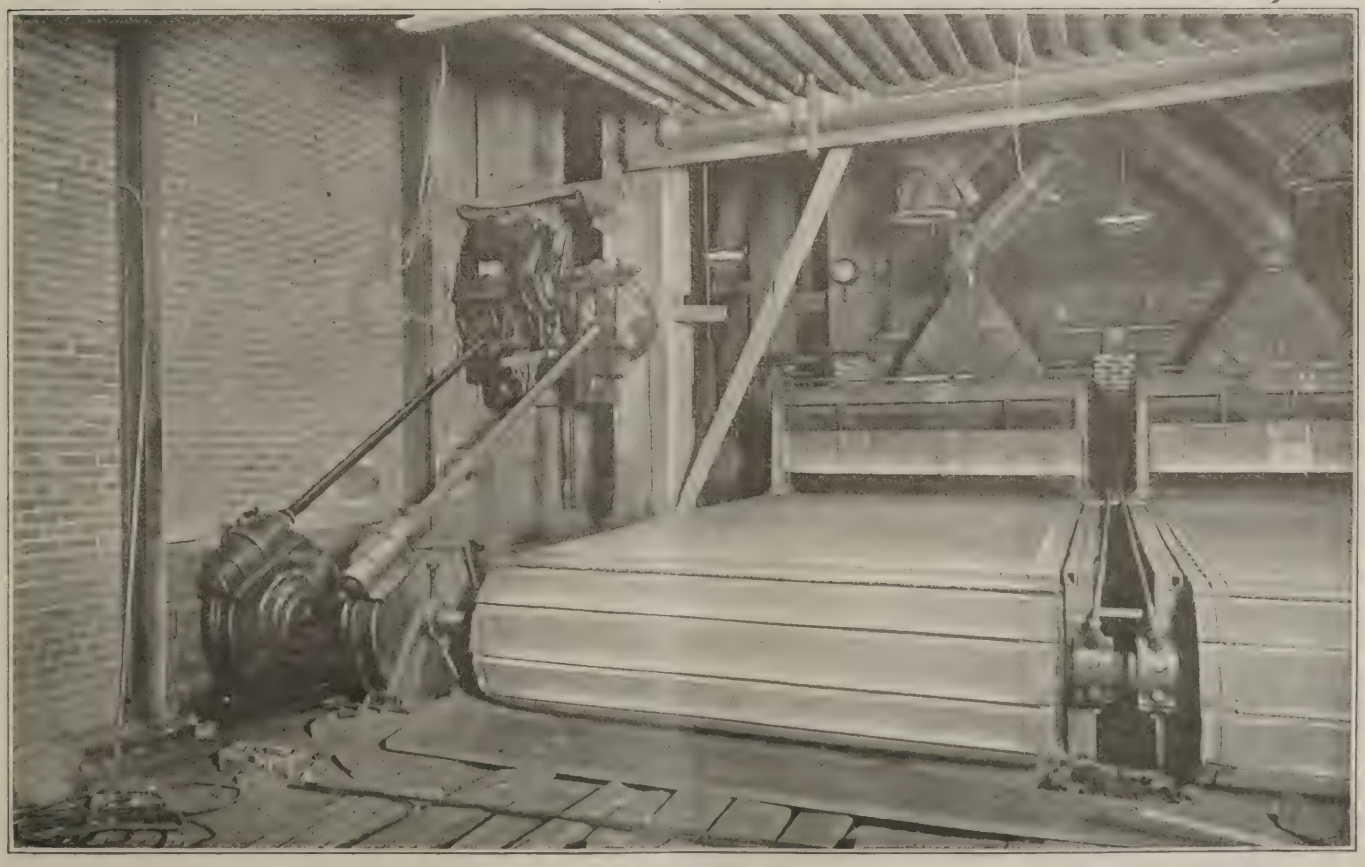

FIG. 7. STOKERS BEING INSTALLED UNDER BOILERS (REAR VIEW); STOKER DRIVE AT LEFT

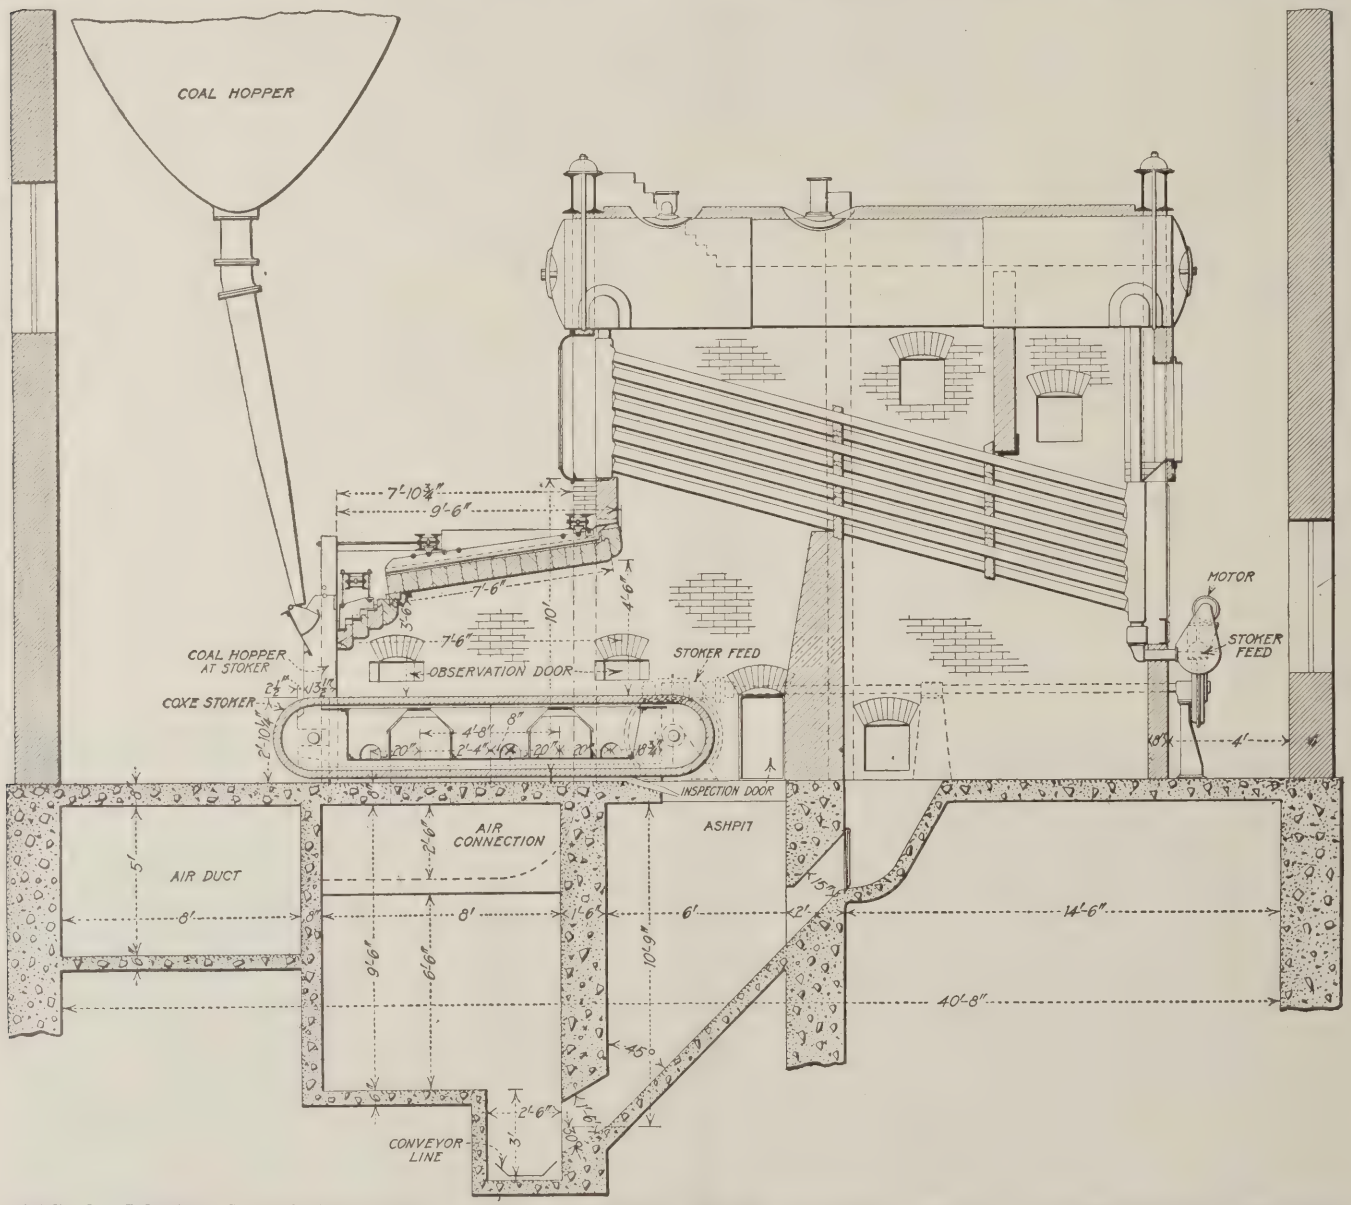
traveling grate with some of the smallest sizes of anthracite buckwheats are shown in Table I.

In commenting on Coxe stoker practice and the table referred to, William P. Frey, fuel engineer of the Lehigh Coal and Navigation Co., states: "As it was found that a rate of combustion of 35 lb. of dry coal per square foot of grate surface was economical for all sizes, this rate was adhered to [in test recorded] as closely as possible by adjusting the speed of the grates and the air supply. As a rough guide for the boiler per square foot, which means that if the grate runs at 16.2 ft. in the case of No. 3 buckwheat, the bed must be carried 6 in. thick. If it is desired to carry only 4 in., the speed of the grate must be increased as 6 is to 4, or 1.5 times, to keep the same rate of combustion. It has to be understood, too, that 25 lb. per square foot is by no means the highest possible rating. The maximum rating obtainable according to our experience is: No. 1 buckwheat, 40 lb. per square foot per hour; No. 2 buckwheat, 35 lb. per square foot per hour; No. 3 buck-



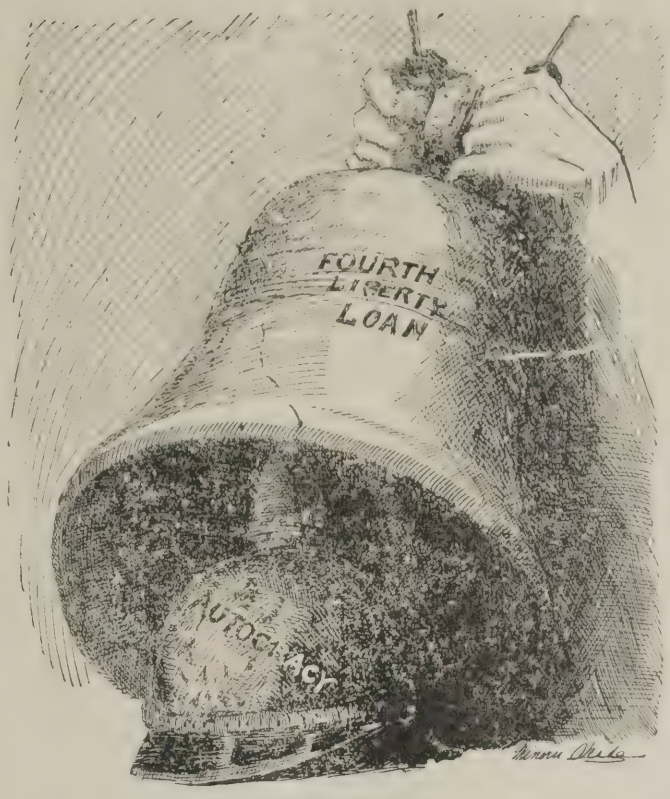


FIG. 8. LONGITUDINAL SECTIONAL VIEW OF STOKER UNDER BABCOCK & WILCOX BOILER, SHOWING METHOD OF ASH REMOVAL AND DRAFT

operatives, the blowers have to be set to deliver 20 cu.ft. of air per maximum horsepower. The air control goes hand in hand with the CO_2 recorder readings (these read 12 per cent. on the average) and the stack temperatures, which are to be kept below 500 deg. F.

"If the stack temperatures are high, the speed of the grate must be increased, the thickness of coal fuel bed reduced and the air pressure under the grate lowered, but the rate of combustion should be maintained as constant as possible. It is important to understand that the figures given in the line in the table—'grate travel in feet per hour'—are relative to 25 lb. of coal wheat, 30 lb. per square foot. per hour; No. 4 buckwheat, 27 lb. per square foot per hour; No. 5 buckwheat and uncleaned silt, 25 lb. per square foot per hour or less. These figures apply to a Coxe stoker with 7 per cent. air space in the grate. Good practice will keep the air pressure in the tuyeres as near as possible to 1 in. at the refuse (ash) end of the grate."

By comparison with the rating given by Mr. Frey, the following data relative to Coxe stokers furnished by John Van Brunt, chief engineer of the Construction Engineering Corporation, of New York City, are interesting: "No. 3 buckwheat can be burned at the rate of

30 lb. per sq.ft. with good efficiency, and as high as 40 lb. per sq.ft. at an expense of 3 to 5 per cent. in efficiency. For No. 4 buckwheat the maximum combustion rate for good efficiency is about 22 lb. per sq.ft.; at the sacrifice of 6 to 8 per cent. efficiency it may be burned at 30 lb. per sq.ft. Silt, or No. 5 buckwheat, can be burned at 16 to 18 lb. per sq.ft. per hour; the ash pit loss is high even at this combustion rate. It is possible to go up to 25 to 30 lb., but the efficiency will drop rapidly; at these higher rates the efficiency would be 40 per cent. or less. All these combustion rates can be maintained indefinitely. Subject to the limitations of the boiler, it is simply a question of providing as much grate surface as is necessary in order to develop as much power as desired." The following statement was made in respect to labor: "If a Coxe stoker plant is properly installed (properly laid out and planned), then one man can handle five or six stokers—that is, 4000 to 5000 developed horsepower. Not including ash handling, a man can look after 10,000 horsepower."

HELP COVER IT

As to the preparation of boiler fuel, Mr. Frey states: "It is evident that it is not only desirable to burn cleaned No. 4 buckwheat, but it is at the same time most economical if ample grate capacity is provided; and there will go hand in hand with the preparation of this size also the washing and concentrating of No. 5 buckwheat. But results show still more conclusively how important it is to use proper methods of firing, and the prime importance of keeping the market free from all fake products of unclean No. 4 and No. 5 buckwheat and uncleaned silt."

A number of the big anthracite companies are using the Coxe grate and reporting most favorably as to its operation. Among these companies are the Susquehanna Coal Co., with 50; the Philadelphia & Reading Coal and Iron Co., 24; the Pennsylvania Coal Co., 14; the Delaware & Hudson Coal Co., 14, and the Lehigh Valley Coal Co., with 6. Furthermore the following statement from an official of the coal-mining department of the Delaware, Lackawanna & Western Railroad Co. is significant:

"In our coal-mining department at present we have 41 Coxe traveling grates installed, six are being installed and 12 are on order. One man can operate ten stokers of the size we are using, and each of the stokers referred to is of proper size for installation under a boiler rated about 300 hp. With the fuel which we are burning we can obtain a capacity of about 150 per cent. and an overall efficiency of about 55 per cent.; this fuel could not be burned successfully with hand-fired operation. The stokers, when using coal which could be hand-fired, would give considerably greater capacity and probably equal, if not slightly higher, efficiency." The coal burned by the Lackawanna company is about the smallest anthracite saved in breaker or washery preparation.

Coal operators formerly believed that coal used about the mines cost nothing, and that in a steam plant only the cost of the plant was to be considered. Now the operator views steam generation as an item of expense involving the use of one ton of anthracite in the production of each eight or nine tons mined. No longer would silt be wasted by diversion to streams, flushing abandoned mine workings or improper stocking. It is not only valuable as raw fuel or in the manufacture of fuel, but by its use at the mines it releases many tons of larger sizes of anthracite better adapted to transportation and for industrial use at points removed from the anthracite field. Thus if silt was used for mine operation purposes, it would release about 8,000,000 additional tons of steam size anthracite that could be diverted to commercial use.

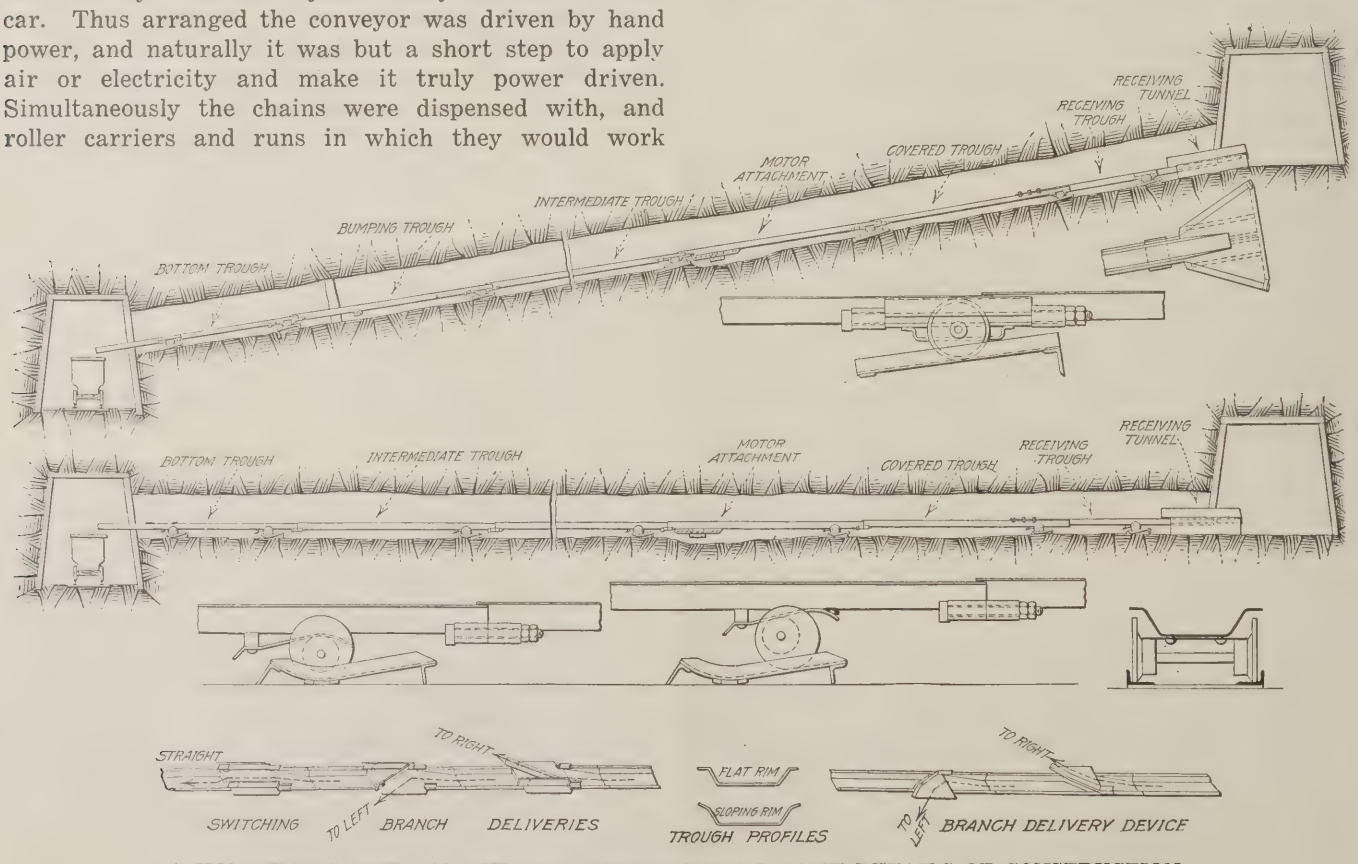
Millions of tons of anthracite silt have been flushed into mine workings, and as large if not a larger tonnage lies scattered about the region in the vicinity of breakers; some of this silt is in shape for recovery. During recent years it has been stocked after it was deposited in settling ponds, and many mines now have a large supply of this stoker fuel readily at hand. One of the large anthracite mining companies stated that it had in sight on the surface, available for immediate use, about ten years' supply of silt for boiler fuel. And each year contributes its quota to this resource of the operators—silt from fresh-mined coal and from the old banks. One admirable way to capitalize this abundant supply of fuel is to burn it on Coxe traveling grates.

On the average the original plant substance from which coal was formed contained about 40 per cent. of oxygen and a comparatively low percentage of carbon. As the process of the formation of coal went on the oxygen was gradually decreased and the proportion of the carbon thereby increased. Anthracite coal contains only about 2.5 per cent. of oxygen and a very high percentage of carbon. With the progress of carbonization, the percentage of the volatile matter also decreases and its quality undergoes a change which makes it easier to burn. Thus, although the oxygen content itself may not directly affect the combustion qualities of a coal it may be regarded in a way as an indicator of such qualities.—*Bureau of Mines Bulletin No. 135.*

A Reciprocating Underground Coal Conveyor

By J. F. K. BROWN
Scranton, Penn.

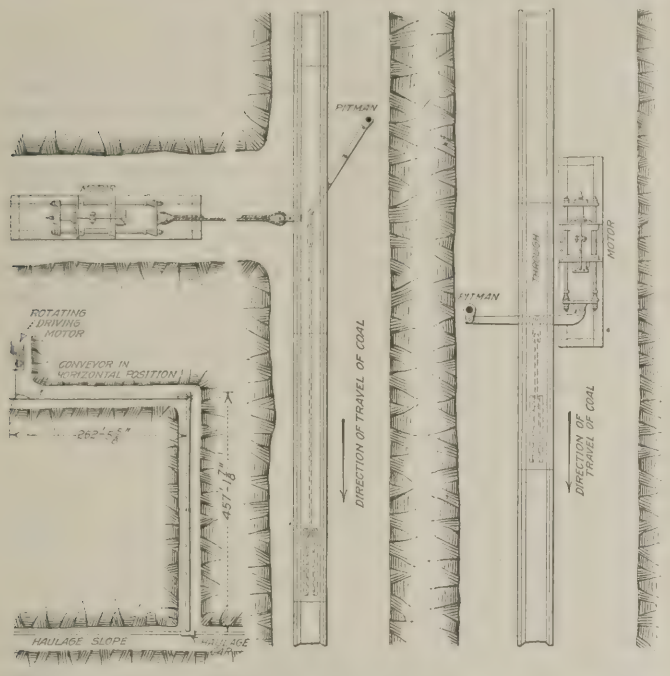
SYNOPSIS—*Some coal beds have an inclination such that cars may be handled to the rise only with difficulty, yet not enough to permit the coal to slide on sheet iron. In such cases the conveyor here described has been used with much success when other conditions were propitious.*



IN THE thin coal beds of the French Pas de Calais field, in Belgium and in Germany, an underground conveyor of a reciprocating type has long been in operation. Although the principle upon which it cperates is not new, its application to underground conditions gave rise to a type of appliance that is popular and has been largely used in the fields mentioned.

The idea originally grew out of the series of sheet-iron plates once used and still in operation in pitching workings, to slide the coal from the faces to the rise to the cars in the level. From that, in beds whose pitch was inadequate to run the coal by gravity, it occurred to someone to lift these plates and hang them by chains to the roadway timbers, and to so set the line of plates thus hung that in swinging them to and fro one end would bump against a tree or wood block at the loading end, the sudden cessation of the motion of the plates causing the coal to continue to slide forward and thus by a series of jerks finally deliver it to the car. Thus arranged the conveyor was driven by hand power, and naturally it was but a short step to apply air or electricity and make it truly power driven. Simultaneously the chains were dispensed with, and roller carriers and runs in which they would work substituted. Thus was evolved the conveyor as it stands today.

Essentially this conveyor works in a similar fashion to an inclined or horizontal shaking screen. The reciprocating motion is imparted to the pans either direct, through a bell crank arrangement, or through a rope arranged triangularly as shown in the accompanying illustrations. Where the inclination is more than 8 deg. this to and fro motion is all that is required, the work of the engine being merely that of pulling the series of pans back up the incline provided by the runways in which the rollers work. On the down stroke the weight of the conveyor and its load is sufficient to impart motion, which is ended abruptly against what is called a bumping beam, the coal continuing its travel along the pans in the direction of the car to be loaded.



On inclinations which are less than 8 deg. this bumping beam is dispensed with, and while the engine still only imparts the to and fro swing, another motion is given to the conveyor. In this case the roller runways are so arranged that the pans rise slowly on the forward stroke and, synchronizing with the turn of that stroke, fall rapidly away from beneath the material carried, which continues its forward direction.

The conveyor itself consists of a series of shallow pans, about 4 in. in depth and of varying shapes and designs, ranging from 19 and 20 in. down to 15 in. in width. Usually these pans are built in lengths of 12 ft. and fastened together so as to form a total length

A HORIZONTAL AND AN INCLINED CONVEYOR AND SOME DETAILS OF CONSTRUCTION

of conveyor up to 400 ft. In the installations designed for workings with over 8-deg. pitch, the various lengths from the top down are known as the receiving trough, the covered trough, intermediate troughs, the motor trough, the bumping trough and the bottom trough. In the other type of installation they are known by similar names, with the exception of the bumping trough, which is absent. The intermediate trough is the only one which is of constant design, each of the others having

TYPICAL ARRANGEMENT OF CONVEYOR AND DETAILS OF TWO METHODS OF OSCILLATION

some particular difference which fixes its position in the conveyor.

The receiving trough is wide mouthed, being so arranged that a car of coal may be tipped onto it in an upper level. The covered trough takes its name from the fact that the receiving trough is so arranged as to cover it and be capable of being slid up or down the requisite distance so as to accommodate any slight variations there may be from time to time in the distance from the loading point to the end of the conveyor. The motor trough, which usually comes next in order downward, has riveted underneath it a steel angle with a series of holes drilled therein to which the extension of the engine piston or bell crank, as the case may be, is attached. This allows for some variation in the exact position of the motor. Below the bumping trough, commonly the second from the bottom, is fixed the bumping beam. The bottom or delivery trough has two roller supports in contradistinction to the others, which have one each.

All the sections of the conveyor are joined together by strong bolts passing through two lugs, one on each side of each section, each section slightly overlapping the one below. Two nuts bring the bolts and lugs together, the top one being a lock nut. On each section at the top end is bolted the carrier plate, which is curved, the lower end of the section being supported by the section below. On the ground below these carrier plates is placed the runway plate, also curved in the fashion indicated in the illustrations.

The rollers that operate between the carrier and the runway plates consist of an axle and an inner and outer roller of different diameters, and with centers that are not concentric. The outer rollers are approximately 10 or 11 in. in diameter, and the inner ones 4 to 4½, while the center lines are offset about an inch. It is this eccentric arrangement, together with the motion imparted by the engine operating through the curved paths of the carrier and runway plates, which gives the peculiar motion up and down as well as backward and forward that causes the coal to travel in the proper direction. In the installations for pitches of 8 deg. and over the paths of the carrier and runway plates are straight, and are then simply inclined planes.

A neat type of air engine is often used to drive the conveyor. This is a single cylinder built into a triangular frame. It is compact enough to go into the thinnest of beds, and is furthermore of such a shape that the height is the lowest dimension, with the width next, which is as it should be for underground work.

The engine foundations are usually timbers about a foot longer than the engine itself, propped against the floor from the roof and fitted under the frame without adding an inch to the height. The engine has a stroke of from 10 to 15 in. and a piston diameter of 6 to 12 in. In order that the piston may be properly guided during its stroke, and also that the drive of the engine may be from either end, a pair of guide rods pass through projections of the engine bedplate from the piston end to the rear, and where they are joined to the crosshead two springs take up the shock of the change of direction of motion. The inlet to the motor is at one end and is manipulated by a crank passing over the top of the engine. When the piston reaches its full stroke, this crank opens the exhaust port, the return swing of the conveyor brings back the piston and rod, and at the bottom of the stroke air again enters.

This conveyor is employed not only in the longwall faces, but also in rooms, and as part of the transportation system where the pitch is greater than that on which a car can readily be handled; also where the coal beds are low. In the longwall faces the conveyor is built the length of the face and stretches in a straight line behind the men working thereon. As the height of the conveyor is small the coal does not require to be lifted very far, and consequently a machine cut face is rapidly loaded away. In this case the conveyor is loaded anywhere along its full length and the loading trough is dispensed with.

In room and chamber work the conveyor is loaded on the end, the broad shovel-shaped extremity of the loading trough facilitating this. Through sections are added to the conveyor as the chamber lengthens.

An illustration is given of the use of this machine as part of the transportation system. Here the conveyor is shown delivering coal along a section 260 ft. in length, into another section 460 ft. long, making a total of 720 ft. before reaching the car. Both these conveyors are driven from one engine, one conveyor driving the other.

An interesting feature is the capability of this conveyor to discharge material if required at any point along its entire length. This is accomplished by the aid of what is termed a branch delivery device, which consist of a specially built series of plates, fitting inside

the conveyor pan, and arranged on such an incline that the material is raised over the lip of the pan and is discharged either to the right or left as desired. As may be imagined in room work wherever rock is made in the mining, this rock can be loaded onto the conveyor after or before the coal and discharged alongside the conveyor line. This is equally handy in a longwall face where rock is made, as it can then be transported and discharged wherever a pack wall has to be built.

While such an appliance has many advantages and has been a decided success in many coal fields, more than 40,000 ft. being in regular operation, it also has some shortcomings. It requires, for example, an air engine, because although it is possible to apply an electric motor, a motion of the type required is much more easily secured from a reciprocating engine than from a motor, whose motion has to be converted into reciprocation by a system of wheels and levers.

Secondly, the conveyor is only suitable for even floors—that is, floors without undulations. Being one continuous line the conveyor requires to be straight and of regular grade throughout its length. Any depression in the line will cause trouble.

A third defect is the inability of this conveyor to deliver material in the reverse direction. While not essential nor common with most conveyors this is nevertheless quite desirable in many mining sections.

Consumers Mining Co. Development

The Consumers Mining Co., of Harmarville, Allegheny County, Pennsylvania (a subsidiary corporation of the La Belle Iron Works, Steubenville, Ohio), is making commendable progress on the concrete lining of the shafts and also on underground work on the coal property the company acquired near Harmarville last April. The mine is 10 miles from Pittsburgh, near the Conemaugh Division of the Pennsylvania R.R., and about 1500 ft. from the Allegheny River. Prepared coal will be shipped by rail and river to the La Belle Iron Works for coking and steam use. The ultimate capacity of the plant has been planned for 5000 tons per 9-hour day, but the proposed surface installation for the present will be equipped for preparing and shipping 2500 tons per 9-hour day. The contracts for the surface building with equipment have not been awarded; the plans show steel construction, which will be fireproof and as modern as the skill and ingenuity of our foremost engineers can design.

The proposed electric hoist will deliver two skips (of three tons each) of coal per minute into a 1000-ton bin; from this bin the coal is to be mechanically fed to a Bradford coal breaker and cleaner. The slate, pyrites, rock, bony and hard coal of high ash content passing out of the end of the screen will be delivered by cars to a dump; or the bony and hard coal will be separated from the distinct impurities by hand picking, if found in sufficient quantity and quality for steam or domestic use. The coal passing through the meshes of the Bradford screen will be directly loaded onto railroad cars or delivered to coal barges on the Allegheny River. This will be done by means of either a system of belt conveyors approximately 1500 ft. long or by electric carriers. The breaker is so located that a crusher can be installed at some future time directly under the breaker for the purpose of crushing the ½-in. coal to dust preliminary to separating the impurities from the coal by washing or by some other modern method. Experimental washing tests indicate that the coal can be cleaned to a sufficient degree to produce a coking coal of approximately 7 per cent. ash content, and less than 1 per cent. sulphur content; this can be done by removing about 8 per cent. of the impurities mixed with the crushed coal.

The Upper and Lower Freeport seams to be mined are separated by a slate and bone band of from 4 to 12 in. The lower seam averages 36 in. in thickness with an ash content of about 4 per cent. and sulphur content of less than 1 per cent.; while the upper seam averages 48 in. in height, with a variable high ash and sulphur content. R. W. McCasland, superintendent of the coal and coke department of the La Balle Iron Works, considers it impractical to attempt to mine the two seams and deliver on cars separately. The owners propose to build about 50 miners' houses in the near future. The ultimate surface plant is estimated to cost approximately $1,000,000.

Neville Island Coal Plant

The United States Steel Corporation's "Ordnance Department," now under construction on Neville Island, adjacent to Pittsburgh, Penn., is to include a comprehensive coal-storage and handling equipment for boiler and producer coal.

Barge coal from the mines on the Allegheny and Monongahela rivers will contribute a large tonnage. Preliminary plans call for a large storage plant with an open yard 150 ft. in width, 670 ft. in length and means for piling coal 50 ft. high, creating a mass of about 90,000 tons.

The high and low water variation of the Ohio River at Neville Island is 35 ft. To protect the coal from water the yard will be inclosed by extensive concrete walls rising about 9 ft. above high-water mark. For track coal unloading pits will be constructed. A traveling coal-handling trolley bridge of about 154 ft. span will be provided with a 7½-ton bucket; it will take the coal from barges and let it fall on the storage yard, or it will take coal from a storage pile and deposit it in hoppers (of 250 tons capacity) directly over the coal-preparation building.

The coal-preparation equipment will consist of mechanical feeders, rolls, crushers and revolving screens, to size the run-of-mine coal for boiler or producer use. The prepared coal is to be stored in pits, one for boiler use of 2400 tons capacity, or 52 hours normal supply, and one for producer use of 3000 tons capacity, or 40 hours normal supply. A stationary coal-handling bridge provided with one 7½-ton and one four-ton bucket will transfer the prepared coal from storage pits to the bunkers over boilers and producers. An ash-handling and disposal equipment is contemplated, also a water purification installation.

Copper ranks next to steel as the most important war metal. Of a world's production of approximately 3,100,000,000 pounds in 1917, the refineries of the United States produced 2,362,000,000 pounds, or a trifle less than 80 per cent.

How Prices of Bituminous Coal Were Fixed by the Fuel Administration*—I

BY CYRUS GARNSEY, JR., R. V. NORRIS AND J. H. ALLPORT
Engineers to United States Fuel Administration

DURING the latter part of 1916 and the early months of 1917, due to war activities, there was a threatened shortage of coal which resulted in panic among consumers and a rush to obtain coal at any price. As result of this insistent demand for immediate delivery, prices were bid up by the consumers to unprecedented heights; spot coal which had previously been selling at from $1.50 to $2 per ton was bid up to $5, $6, and, in exceptional cases, as high as $7.50 or more per ton. Then when the April, 1917, contract period arrived, contracts could be made only at prices ranging from $3 up to $5 and $6 per ton for the year's delivery. This condition caused such a demoralization of the business, and so much complaint, that some action to regulate prices was considered essential by the National Administration.

In May, 1917, a committee under the chairmanship of F. S. Peabody, of Chicago, was appointed by the Council of National Defense, through Mr. Lane, to consider the whole question of bituminous coal. This committee, with the Secretary of the Interior, Mr. Lane, after numerous meetings and long negotiations with the operators throughout the country announced on June 29 an agreement between the committee and the producers, fixing a tentative maximum price for bituminous coal throughout the country at $3 per net ton f.o.b. mines, to which was added 25c. for selling commission to wholesalers. This plan was based on the idea of fixing a maximum price, high enough to greatly stimulate production, with the expectation that the laws of supply and demand would, with ample production, operate to maintain fair and just prices for coal throughout the country.

With the country plunged into the greatest war of history, it became evident that distinct power should be given the Administration to control efficiently war necessities, food and fuel, needed in ever-increasing amounts, not only by our own country but by our allies, and for our armies in this country and abroad. With this in view, the Sixty-fifth Congress passed House Bill No. 4961, generally known as the "Lever Act," entitled "An Act to provide further for the national security and defense by encouraging the production, conserving the supply, and controlling the distribution of food products and fuels." It was approved Aug. 10, 1917.

Section 5 of the Lever Act authorizes the licensing of "the importation, manufacture, storage, mining or distribution of any necessities"; and Section 25, "to fix the price of coal and coke, whenever and wherever sold, either by producer or dealer." It is further provided in this section "in fixing maximum prices for producers, the commission shall allow the cost of production, including the expense of operation, maintenance, depreciation and depletion, and shall add thereto a just and reasonable profit." "In fixing such prices for dealers the commission shall allow the cost to the dealer and shall add thereto a just and reasonable sum for his profit in the transaction."

[The powers of the Federal Trade Commission as to coal were, with certain minor exceptions, transferred to the United States Fuel Administration by order of the President on July 3, 1918.]

On Aug. 21, 1917, the President announced prices for bituminous coal throughout the United States, specifying prices for run-of-mine, prepared sizes, and slack or screenings, by states and, in a few instances, by districts or by seams. These prices for run-of-mine coal varied from $1.90 to $3.25, and were, in general, a very great reduction from the prices fixed by the Lane-Peabody Commission. These prices were based on average figures on about 100,000,000 tons production, prepared by the Federal Trade Commission, from the very meager data in its possession, generally costs from the larger and lower-cost operations of each district.

On Aug. 23, 1917, Harry A. Garfield was appointed United States Fuel Administrator by the President, and to him was delegated the powers as to fuel, conferred by said act on the President. On the same day, by Presidential proclamation, prices were fixed on Pennsylvania anthracite coal. From this date until early in January, 1918, numerous revisions and adjustments of "the President's prices" were made by the Fuel Administrator, but no general revision was attempted.

Early in January, the Engineers' Committee was constituted, and to this committee was entrusted the making of a general review of costs, and the submission to the United States Fuel Administrator of the results of careful studies of the costs of producing coal throughout the United States. The committee was not then, and never has been, authorized to fix prices on coal; the limit of its duties has been to study and report on methods of price fixing and to determine and furnish costs, leaving to the Fuel Administrator the personal duty of determining the amount of margin to be allowed.

The committee's first work was a study of price-fixing methods which were, or might be, applicable to coal-producing conditions. In arriving at a logical and scientific plan for fixing the price of fuel the following methods were considered:

1. *Straight Cost Plus Method.*—The actual cost at each colliery plus a fixed sum or percentage of profit.

2. *Modified Cost Plus Method.*—The actual cost at each colliery plus a graduated profit decreasing as costs increase.

3. *Average Cost Methods.*—Prices fixed on the average cost in each district.

4. *Pooling Methods.*—All coal sold at the average cost of each district plus a profit, and the returns to each colliery adjusted through a clearing house at a price proportioned to its cost of production.

*Paper presented at the Colorado meeting of the American Institute of Mining Engineers, September, 1918.

Discussion of Advantages and Disadvantages of These Methods

1. *Straight Cost Plus Method.—Advantages.*—(*a*) All producers would receive the same profit, and no one would have an advantage over another in this respect. (*b*) Apparently simple in plan and execution.

Disadvantages. — Impracticable of application, by reason of: (*a*) Resultant multiplicity of prices, with grave disturbance of markets. (*b*) Continual changing of prices due to inevitable variations in each producer's costs. (*c*) Instability of the industry, due to the natural disposition of consumers to purchase the lowest-price coal. (*d*) Inefficiency in operation always resulting from lack of incentive in cost plus operations. (*e*) Material reduction in output and reduction in quality due to the natural tendency to mine the poorer and more expensive coal with a guaranteed profit, and to leave the better and cheaper coal in reserve to be mined on the return of normal conditions. (*f*) Continual increase in all costs incidental to extravagant methods encouraged by guaranteed profits. (*g*) Labor unrest and constant demands for increases due to the knowledge of a guaranteed profit regardless of cost. (*h*) Practical impossibility of arriving with technical accuracy at the costs of each separate operation. (*i*) Impracticability of the Government's policing the mines and securing the same efficient operation and production attained by the individual producer under the stimulus of increased profits. (*j*) Illogical, in that the better planned and managed operations are discouraged, as compared with poor and inefficiently managed properties.

2. *Modified Cost Plus Method.*—This is but a modifi-

cation of the preceding, and the same discussion applies, modified only by the inclusion of a somewhat greater incentive to the better and more economical operations.

3. *Average Cost Methods.—Advantages.*—A minimum uniform price for each district or, if desired, for the entire country.

Disadvantages.—(*a*) The average cost is necessarily less than the cost of about half the total tonnage. Hence, a reasonable profit put on the average cost would not produce the necessary tonnage. (*b*) The tonnage below and up to the average cost is actually produced by less than 30 per cent. of the operators of the country. Hence, the great majority of the operators producing at above average cost would be put out of business by a price based on the average.

4. *Pooling Methods.*—Pooling may be done on either cost plus, modified cost plus, or on the prices established by the United States Fuel Administration.

Advantages.—(*a*) A uniform price to consumers for sections and, if desired, for the entire country. (*b*) A present lower price to consumers based on weighted average cost. (*c*) A simplification of all present pooling arrangements, as all coal to each pool would have, or could be arranged to have, the same price. (*d*) A return to the consideration of quality instead of cost, as, with all coal at the same price to consumers, the higher qualities would naturally be preferred.

Disadvantages of Pooling Cost Plus on Modified Cost Plus Methods.—(*a*) Continual variation in pool prices, due to inevitable variations in producers' costs. (*b*) Unfair and illogical, in that the better located and managed operations are made to pay tribute to the poor and badly managed ones. (*c*) A general and considerable increase in cost inevitably resulting from any method involving guaranteed profits with a disregard of economy. (*d*) A material reduction in output, due to lack of incentive and resulting inefficient methods, the employment of unnecessary labor, the mining of the more expensive and less desirable qualities of coal for the ultimate benefit of the mines, and the execution of development not immediately needed. (*e*) A slacking of the efforts of employees, which is the usual result of a lack of incentive to the producer, with the resulting lack of interest. (*f*) The installation of an unsound policy tending to encourage the inefficient and discourage the efficient producer. (*g*) The ever-present temptation to allow costs to increase with the hope of readjustment of prices. (*h*) Dissatisfaction to both labor and to producers from the knowledge that other and less efficient operations have higher limits of price.

The disadvantage of pooling on the prices fixed by the United States Fuel Administration are the same as suggested above, without some of the special disadvantages of cost plus methods.

Disadvantage of Pooling in General.—(*a*) A very large capital required to handle such stupendous operations. (*b*) Enormous and extended credit required to finance the producers. (*c*) Lack of organization to handle this new business. (*d*) Undesirability of creating such an organization with its army of additional employees at the present time. (*e*) Inadvisability of putting a new and untried plan into operation at the present time. (*f*) Impossibility of obtaining, with sufficient promptness, the costs necessary to fix pooling prices with the necessary accuracy. (*g*) Interference with present established methods of handling coal, with serious risk of crippling its distribution and unnecessarily creating a shortage.

None of these suggested methods seemed to fill the peculiar conditions incident to price fixing of coal at the mines, and it devolved upon the Engineers' Committee to develop some method better suited to the conditions of the problem.

The Price Fixing Method Adopted

The study of the conditions indicated the necessity of finding a method of price fixing which would fill as nearly as practicable the following requirements: (1) Result in a price fair to the public. (2) Prevent excessive prices or profiteering. (3) Prevent a multiplicity of prices in any district. (4) Encourage legitimate production. (5) Discourage production from inefficient and unduly costly operations. (6) Insure to the producer "the cost of production, including the expense of operation, maintenance, depreciation, and depletion, with a just and reasonable profit," as required by the Lever Act.

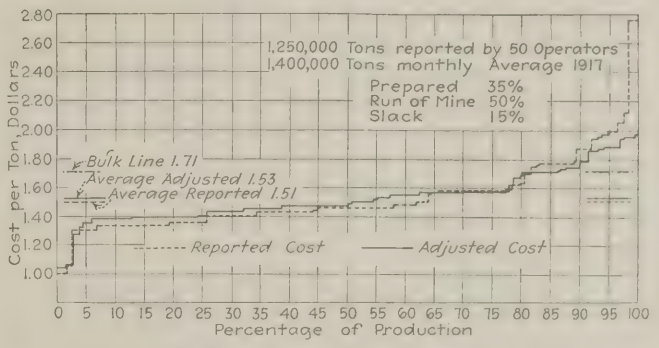

FIG. 1. HOW PERCENTAGES WERE PLOTTED

In arriving at a method promising to accomplish these results as nearly as practicable, the following system was developed. Costs obtained from the individual sheets filed by each operator with the Federal Trade Commission were studied, listed and adjusted for price fixing. These figures, with the percentages of each cost in the total production of each district, were plotted on diagrams, showing graphically the range and extent of variation in each district. On these diagrams a line indicating the sources of indispensable tonnage, christened "the bulk line," is drawn as a base to which the Fuel Administrator personally adds a margin in his judgment necessary for each district.

Advantages of This System.—The method of fixing prices by the "bulk line" principle recognizes the economic syllogism that "the price of any article necessary to a community will be fixed by the cost of producing that necessary portion of such article involving the greatest expense." (*a*) This assures to all producers profits dependent upon their ability and exertions, only limited by the establishment of a reasonable price to the consumer. (*b*) It does not unduly increase the price of coal to the consumer over the minimum price possible under other methods. (*c*) It tends to encourage maximum production and necessary development by allowing to the producer the benefit of reduced costs due to greater production. (*d*) It avoids bad feeling among the producers and among the workmen by allowing a fixed price in each district and not apparently

showing favoritism to special producers. (*e*) It tends to encourage the fit and discourage the unfit. (*f*) The method is susceptible of refinement and extension, making it possible to eliminate undue profits to the producer and adjust prices from time to time to the ultimate advantage of the consumer.

Disadvantages of This System.—(*a*) Considerable profits to the lowest-cost operators. (*b*) A price for coal greater than one based on the average cost, by the amount by which the "bulk line" exceeds such average. This method appeared to be better suited to the conditions than any of the others suggested, and after a careful study by the United States Fuel Administrator, it was adopted.

The Federal Commission had, by authority of the Act of Congress creating the commission, the power to investigate costs, and to require, under penalty, reports of costs of operation. Under this authority the commission sent out to each coal producer listed in the United States blanks requiring a rather complete and detailed statement of costs of operation, and the realization obtained from the sale of his product. These reports were generally available for the months of August and September, 1917, at the time the revision of prices was started, and reports for these two months, studied in connection with later reports, were generally used as a basis of costs for the first studies. It further developed that these two months were, in most instances, fairly representative, as to output, of the average of the year.

Without desiring to impugn either the honesty or the accuracy of the cost sheets as presented, it was found essential to study and adjust them for use as a basis of scientific and accurate cost finding. Besides correcting slips and palpable mathematical errors, a considerable amount of revision was necessary. Many, especially of the small operators, were inexperienced in bookkeeping and submitted cost sheets which, while accurate in totals, were grievously mixed in details.

Supplies.—The item of supplies was found to vary so widely in the same mines in different months that the returns for single months were practically abandoned,

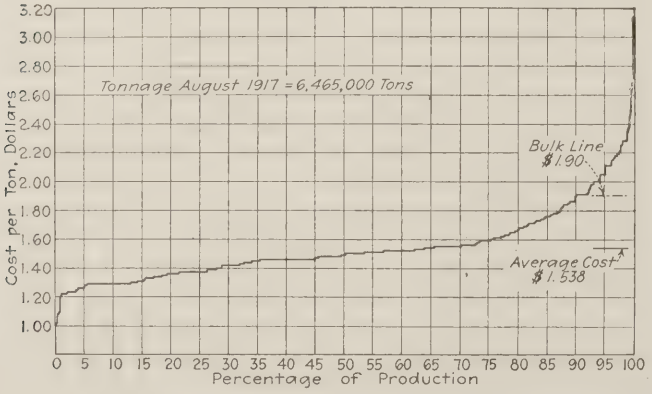

FIG. 2. SHOWS COSTS FOR AN ENTIRE AREA

and the figures were replaced by averages from all reports available, resulting in increases or deductions from the monthly costs as reported.

Reserves.—The item of maintenance was frequently misunderstood, in some instances all supplies and much labor being charged to this account; in others a fixed sum, and in still other cases, nothing at all was charged. Depreciation was often put in as a guess; in some cases it was frankly stated that this seemed a good time to charge off improvements, and such were charged to the limit, and beyond.

Depletion of lands was also an item which appeared greatly to trouble some of the accountants. While generally understood, many very wild guesses, even up to the market price of the product, were found; also, many instances of depletion charges for lands operated on royalty or lease and not the property of the operator.

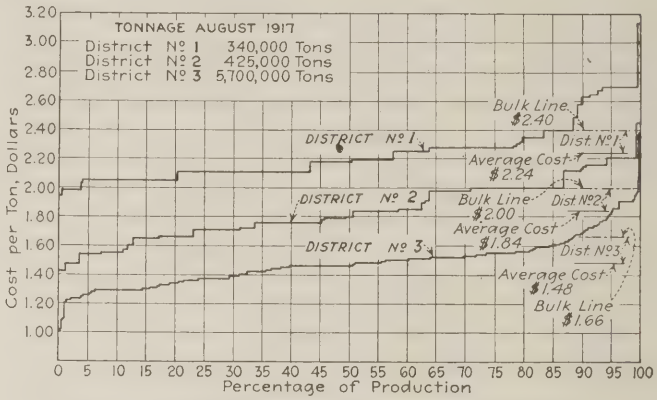

FIG. 3. SHOWS COSTS IN THREE DISTRICTS

Contingent funds noted on the blank were generally omitted but, in a few cases, especially when the need of such funds had recently been felt, most ample allowances were made. After being considered, it was decided to apply in each district amounts obtained by studying the claims of the better operators of such district, after obtaining, from the best available sources, reliable figures as to the cost of lands and amount and value of improvements characteristic of the district.

The question of contingent reserves is a serious one. From a strict cost-accounting standpoint, no cost can be permitted until incurred. Nevertheless, such reserves are essential to an industry involving the great risk incident to coal mining, and with the full knowledge that such reserves are used only for major accidents or calamities, and that ordinary losses regularly incurred are charged to the costs of operation, it was decided to include a small amount for contingent reserve in the general allowance.

Salaries—Executive and even superintendent's salaries were frequently omitted. In many cases of personal ownership, undoubtedly none were paid. It was considered only just to add to such returns reasonable allowances for salaries to place such reports on a parity with the majority of the operations which paid for such necessary service. On the other hand, occasional instances were found of reported salaries so excessive as to require adjustment downward to a reasonable parity with the general practice of the district.

A sliding scale of salaries adjusted, within broad limits, to the monthly tonnage of an operation was finally devised. Any salaries missing or below the minimum allowed were raised to the minimum, and those above the maximum were lowered to the maximum.

Special Charges.—Special charges were generally treated in details, often spread over a reasonable time rather than allowed in a single month. In treating these a careful study of all reports available was made.

Special Records.—The Federal Trade Commission had required special explanations of all charges out of the ordinary, and all these records were available and were carefully studied and had great influence in deciding doubtful points.

Outside Profits.—The profits from farms, dwellings or stores are not properly mining profits, and accounts of these should be kept separate from mining expense. Where it is found that such accounts are separated, no deduction for such profits should be made; but where dwellings, particularly, are so intimately connected with the mining that no separation is possible, it is proper to include their operation with mining accounts.

Fuel for Power.—In general, charges for fuel for colliery power were allowed, and the tonnage divisor was made to include such fuel. In the opinion of the committee it would, however, be advisable to eliminate colliery fuel from both sides of the account and merely to keep a record of the amount used; by this method, the tonnage divisor represents the amount shipped and sold and is susceptible of accurate determination, while the fuel used is approximated, or even guessed at, too often to make the general records containing this item reliable.

Other items requiring occasional adjustment were the inclusion of washing costs, for which an extra charge is allowed, in the mining cost, and the inclusion of labor and supplies used in coking operations conducted by the same operators. In a few instances, the coke tonnage, or a mixed tonnage of coal and coke, was reported and used as a divisor to obtain costs per ton, resulting, of course, in a notably excessive cost

In general, each and every cost sheet was studied carefully by at least one member of the committee, all adjustments were considered by at least two, and only such adjustments were made as were warranted by the conditions and the necessity of placing all costs on the same basis, so as to find a just basis of cost for fixing the prices for each district.

(To be continued)

Advantages of Using Power Gas

By Mark Meredith
Liverpool, England

As power gas is likely to come largely into use in the near future, it is interesting to recall that the first apparatus for its manufacture from coal dust, and for the recovery at the same time of sulphate of ammonia, was designed and patented by Ludwig Mond and built at Brunner Mond & Co.'s Northwich, England, works.

The advantages of using power gas can be summarized as follows: The cheapest quality of coal, even pit-head refuse, can be used; and consequently power can be obtained in addition to valuable byproducts without the use of expensive steam coal. Very little labor, and that of only an unskilled character, is required. The heating value of the gas is equal to, roughly, about 86 per cent. of the total heat energy contained in the fuel from which it is produced, and it can be obtained on a large scale for a mere fraction of a penny per 1000 cu.ft.

What this means will be realized when it is mentioned that one ton of rough slack will provide upward of 150,000 cu.ft. of power gas having a calorific value of at least 140 B.t.u. per cubic foot. The quantity of gas required to produce an indicated horsepower-hour in a large gas engine varies, but may be taken as being about 50 to 60 cu.ft.

One ton of low-grade coal, gasified, and used in a modern gas engine, will produce at least 2500 i.hp.-hr., or 2500 hp. for one hour. That is to say, a ton of this coal converted into power gas will produce about 500 per cent. more power than it would were it burned under a boiler in the ordinary way and the steam used to drive an ordinary reciprocating engine. Taking the price of slack at as high a figure as 12s. ($3) per ton, delivered, the fuel cost of an indicated horsepower-hour obtained by power gas would not exceed one-twentieth of a penny.

It has been pointed out, and rightly, by the advocates of the use of power gas that in every steam plant working with a variable or intermittent load a considerable percentage of the fuel is wasted. Some loss under this head is unavoidable, but it was early realized that the employment of power gas reduces such standby losses to a minimum.

In the early forms of producer the apparatus was provided with a water seal so arranged that the ash, which is the only residue, descended into the water, from which it could be easily removed. The process of combustion was carried out at a comparatively low temperature, which not only prevented the formation of clinkers but provided against the destruction of any of the byproducts.

This result was accomplished by blowing a blast of hot air and steam into the producer. The quantity of steam required when it was desired to recover the ammonia was equal to about 2½ tons for every ton of fuel gasified. Of this about two-fifths was afterward recovered. When the process was first used comparatively little attention was paid to the recovery of the ammonia, and the quantity of steam used in such case was about one ton for every ton of fuel.

In connection with the plant a regenerator was used, through which the gas passed. In this, part of the heat was transferred to the blast of air and steam on its way from the air-heating tower to the producer, the gas being cooled to a corresponding extent before it was delivered to the mechanical washer. Here a system of rapidly revolving dashers kept a fine spray of water passing through the gas, which not only reduced its temperature but cleansed it from dust and particles of carbon. From this washer the gas passed into an acid tower, where the ammonia content was removed by a weak solution of sulphuric acid with which it was brought in contact, in this manner forming sulphate of ammonia.

This solution was passed continuously through the stream of gas until it contained about 35 to 40 per cent. of sulphate. In order to provide for continuity fresh acid was introduced periodically and corresponding quantities of the sulphate liquor removed. This was then evaporated into solid form, after which it was crushed and sold as fertilizer, while the gas was passed into a cooling tower in which it was again thoroughly washed. Modern methods have improved to some extent on this process, but substantially it remains much as it did when it was first brought to the notice of engineers by Mr. Mond.

Origin and Development of the Ventilating Fan

SYNOPSIS — *The mine fan as we know it today had an ancient and humble origin. As the duty imposed by mine ventilation has increased, fan design has been improved to meet the requirements. Today several distinct types exist, each possessing peculiar advantages that render it particularly well adapted to certain circumstances.*

TO PROPEL air by mechanical means is a principle that dates back to antiquity. The methods at first used were primitive and not until comparatively modern times has any machine been devised that could be operated with sufficient economy to insure its commercial success. Also, the necessity for the development of mechanical ventilating equipment has only been brought about by the needs of the people of today. The various problems to which fans have been applied have only been developed during a comparatively modern time, and we find the application of fans, previous to this period, limited to the winnowing of grain and to the propulsion of cooling air in warm climates. Formerly these duties were accomplished by hand-operated fans of various designs, some of which still remain with us.

The most important fact in the development of the fan is that in the early days the only means of power were water, wind and hand. This, of course, limited the use of the mechanical equipment. Water-power was used to a certain extent, but due to the necessity of a favorable natural location it was little used for ventilation, although it was employed in the threshing industry. Wind-power was used quite extensively for various purposes, but since when the wind blew mechanical ventilation was not needed, it had no application so far as ventilation was concerned.

Hand-power was therefore used almost exclusively for mechanical ventilation. This, of course, had its application in warm climates only, and many of the methods used were unique and primitive. It is still quite a common sight in many places, even as near home as the West Indies, to see little negro boys sitting or standing behind members of the family, fanning continuously with large palm fans in order to keep the air in motion.

Another peculiar yet common means of creating an air current is to suspend a large piece of ornamental carpet or other fabric from the ceiling in the center of the room, and extending the full length. This fabric is fitted with a rod which passes through the entire length of the bottom edge. From the center of this rod a small cord is run through a hole in the wall of the room. A servant sits on the outside and slowly pulls the cord, thus swinging the entire curtain back and forth over the heads of the family, whenever ventilation is desired.

With the perfection of the electric motor, steam, gas and gasoline engines came forms of mechanical power not limited to a natural location or weather conditions. Thus there became available a constant positive source of power that has completely changed the early ideas of ventilation and made possible the high type of fan design with which we are familiar today.

It is not surprising that the machines used today for propelling air resemble strongly those used in the development of power from wind and water. The simplest of these machines, and one of the earliest, is the disk fan. This type, primitive as it may be, has a certain gap to fill in duties of fan performance, to which it is especially adapted, and where it gives better performance than even the most modern types of centrifugal machines. This duty is the handling of a large volume of air against a small pressure or against no pressure at all. Under this condition the disk fan will handle more air with less power than any other type, and for this reason we see it used almost exclusively for distributing the air in a room in order to produce a higher rate of evaporation on the skin of the occupants and thus produce a cooling effect.

As soon as a fan is used in connection with any pipe or other apparatus, however, a different condition arises. The disk fan has so much space for back leakage that as soon as it builds up a pressure ahead of it the tendency of this pressure to release itself will cause a flow of air back through the fan. This will increase as the static pressure ahead of the machine increases, until the back leakage equals the capacity of the fan and the blades simply revolve without effectively moving any air.

Disk Fan Will Handle Large Volume of Air

To overcome this, many forms of this fan have been devised, some of which produce positive pressures and seem to operate better when used against them; but in each case the pressure against which the disk fan will successfully operate is so small that for only the most simple and small installations are they considered advisable.

It was found in the use of the disk fan that even when the machine was producing a tremendous back leakage it still handled large volumes of air in a radial or centrifugal direction. In order to utilize this radially directed air, we find ourselves in possession of an entirely different type of fan, which has been called the cone fan. The name of this machine is derived from the cone-shaped plate at the rear of the fan that is used for directing the incoming air in a radial direction. This air is then picked up by the blades of the wheel and given a rotary motion. The momentum of the air, caused by centrifugal force, carries it through the wheel at a considerable velocity and produces a static pressure throughout the entire room in which the fan is placed. This room then becomes a plenum or pressure chamber in which sufficient pressure is created to force the required amount of air through the pipes or ducts leading from the fan to where the air is to be used.

This fan was a decided improvement over the disk

type in that it made it possible to produce a delivery of air against a greater resistance. The greatest pressure available, however, is equal only to the centrifugal pressure of the wheel, and this in turn is transmitted over so great a room surface that the entire velocity pressure or momentum effect of the air is lost and a comparatively small pressure is available for producing a flow in the outlet pipe or duct.

The constant demand for ventilation, however, called for a fan having a large capacity of air against a considerable pressure and requiring a minimum power to drive. A tremendous stride was made in this direction by taking the cone fan wheel and encasing it in a steel plate housing having two straight sides, with inlets at the center, and a scroll sheet encircling the rim, patterned after the well known logarithmic spiral. This machine is usually built with eight blades and produces a large delivery against a positive pressure. It requires only a moderate expenditure of power. Special designs of this fan have been known to operate against 16 to 18 oz. of pressure and still deliver a large volume of air, although the power consumption then became enormous. The most important fact that can be stated about this old reliable type of fan is that its efficiency is high.

Advantages of Steel-Plate Fan

The steel-plate fan is built with either curved or straight blades. The earlier fans were all straight bladed, and even now the high duty fans, such as pressure blowers, have straight vanes with which higher efficiencies are obtained. The theory is that to obtain the proper centrifugal force the force must be in a radial direction. Due to the fact that the wheel has some slippage, or gains on the air a little, the blades were curved back to allow the air to pass back on the wheel and still travel in a radial course. As the air nears the tip of the wheel the component of pressure in the radial direction is thus increased. This results in a greater capacity to overcome resistance, but the power required to operate it is about the same. The same results can be obtained with the straight-blade fan by driving it a trifle faster.

As soon as we pass from the steel-plate machine to the next and latest step in the evolution of the fan, as applied to ventilation, we have no longer a centrifugal fan, but an air turbine, differing so radically from the older types of paddle-wheel machines that the entire principle of air delivery is changed. This type is known as the multiblade fan, of which type the "Sirocco" is probably best known.

The multiblade fan develops an enormous air delivery, accomplishing this by means of a large number of shallow blades. As mentioned in the theory of the steel-plate fan, the air should have a straight radial movement from center to tip of the blade, and even in a perfectly frictionless case the maximum speed or velocity at which the air would leave the tip of the wheel would be equal to the peripheral velocity of the wheel itself. As the steel-plate fan, however, is only about 60 per cent. efficient, the maximum practical velocity of the air leaving the wheel is only 60 per cent. of the peripheral velocity of the wheel.

In the case of the multiblade fan, however, the movement of the air over the blades has three distinct stages. The first is when it is picked up by a lip or scoop at the inner edge of the blade. This lip picks up the air and starts it in a radial direction and at the same time produces a component pressure in that direction, which materially overcomes the tendency for back leakage. Once caught in this scoop the air is passed to the second part of the blade and into its second stage. The second part of the blade is practically radial and the rotation of the wheel causes momentum, due to the centrifugal force carrying the air into the third stage. The third stage is accomplished by decidedly curving the outer edge of the blade forward in the direction of the rotation of the wheel. It is evident that in the movement from the second to the third stage the air must travel faster than the wheel itself. Since the point of the blade is ahead of the radial point, the velocity of the air leaving the wheel must be greater than the peripheral velocity of the wheel itself.

The speed of the air can be increased by increasing the forward curvature of the blade until the theoretical limit is reached, at which point the air would leave the wheel at a velocity equal to twice the velocity of the wheel itself. Assuming that the multiblade and steel-plate fans are of equal efficiency, the practical velocity of the air in the multiblade fan would be 60 per cent. or twice the peripheral velocity of the steel-plate wheel.

It is evident, therefore, that for a certain air delivery, since the velocity is greater, the area required may be reduced. This permits decreasing the diameter of the wheel used, with a corresponding decrease in the size of the casing. Hence in this type we obtain a smaller fan, which will accomplish the same results as the older steel-plate machine.

So far, no account has been taken of the power required, and we can simply say that an air-horsepower is an air-horsepower in any case, and the power consumption would only be governed by the actual efficiency of the fan itself. The multiblade, however, has a particular advantage in the smaller percentages of restriction.

In conclusion, each of the fans considered in the foregoing possesses a particular adaptation to the various forms of ventilation, which makes each indispensable. Since conditions vary, no hard-and-set rule can be laid down for any given type, each particular case requiring individual attention to determine the proper fan required.

Generally speaking, the disk fan is suitable where a free delivery or only slightly restricted duty is required; the cone fan is suitable where the pressures exceed the limit of the disk fan and where price prohibits the use of a blower. The steel-plate and multiblade fans may be considered together as being applicable to ventilation in general, the preference being shown the steel-plate machine where space is of minor importance, and to the multiblade fan where space is of prime importance.

A saving of coal equivalent to 350,000 tons annually already has been effected by the Fuel Administration in its conservation campaign among the steam power plants, it is stated officially. This saving has been effected through the inspection of 300 plants. It is the intention to inspect each of the 250,000 steam plants of the country. The saving is declared to be the result of applying more efficient firing and operating methods.

Waste Due to Excessive Ash in Coal

THE J. G. White Engineering Corporation of New York, with the permission of the National Research Council, is distributing its report to Gano Dunn, chairman of the Engineering Committee of the Council, on "Clean Coal and the Effect of High Ash Upon Thermal Efficiency, Amount of Boiler Plant and the Amount of Transportation Equipment." Although this report is dated Jan. 16, 1918, so pertinent and timely even now are the facts set forth that it is here reproduced practically in its entirety. The report follows.

AS FAR as possible, the elimination of slate and other ash-forming impurities in coal, before delivery to railroad cars, will prevent serious economic waste in its utilization and transportation. It is difficult to completely cover this subject in a short report, because of the widely varying uses to which coal is put; but since the major portion of the coal mined in this country is used for the generation of steam, the actual proportion being about 67 per cent. of the total coal output, a discussion of this economic waste in the generation of steam will cover the most serious losses. The losses in other uses of coal will be similar, but of a different degree. These wastes may be briefly summarized as follows:

1. Reduction in Heating Value of Coal Due to Presence of Ash—The presence of ash in coal not only reduces its heating value, but as the percentage of ash increases the percentage of combustible lost with the ash also increases, thus greatly reducing the boiler efficiency and hence lowering the economic value of the coal. (See Fig. 1.)

2. Increase in Coal Consumption for a Given Power—The reduction in boiler efficiency greatly increases the amount of coal that must be purchased to produce a given amount of work. This is a direct financial loss, since the consumer is not only paying for unnecessary ash, but is losing good fuel which is carried off through the boiler grates with the excessive ash. (See Fig. 2.)

3. Influence of High Ash on Boiler Capacity—The presence of excess ash seriously reduces the boiler capacity, because sufficient coal cannot be burned on the grates to do the necessary work. This is possibly the effect which is felt most seriously by the consumer, because he finds it impossible to get sufficient steam from his boilers to do the work demanded of them and is compelled either to reduce his output or purchase additional boiler capacity. (See Fig. 3.)

4. Increase in Transportation Equipment Due to High Ash—About 85 per cent. of all the coal mined in this country is carried by the railroads, hence unnecessary ash means an unnecessary task imposed upon these carriers. Each per cent. of avoidable ash adds to the work of the railroads about 5,000,000 tons of unnecessary freight per annum. Some shipments of coal contain 18 or 20 per cent. noncombustible. Such coal requires 65 per cent. more cars and locomotives than a reasonably clean coal of say 10 per cent. ash. (See Fig. 4.)

The heating value per pound of combustible (that is, ash- and moisture-free coal) of all coals approximates 15,000 B.t.u. There are some variations from this figure, but as a general average it is about correct. The variation in the heating value of coal is consequently largely due to the varying percentage of the ash—the effect of moisture being less important except in a few cases of unusual moisture content. If we could obtain an ash-free coal, we should expect a heating value of about 15,000 B.t.u. per pound. The heating value by test of any commercial coal is reduced approximately in proportion to the increase in the percentage of ash, but its value as a heating agent is reduced more rapidly.

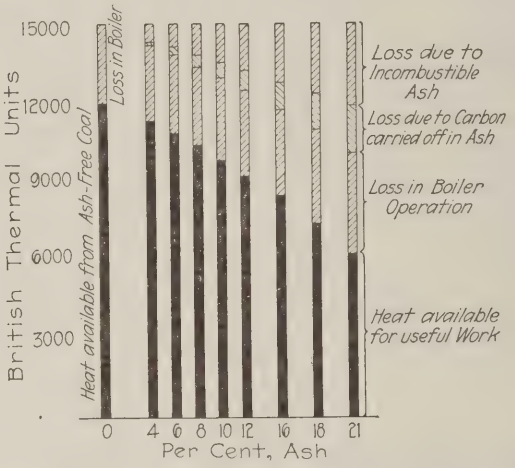

FIG. 1. REDUCTION IN HEAT VALUES DUE TO PRESENCE OF ASH IN COAL

The percentage of ash has a distinct influence on the boiler efficiency. As the quantity of ash increases in percentage, it becomes more difficult for the fireman to completely burn the combustible. With a low percentage of ash and good firing we expect the ash removed from the boiler to contain approximately 25 per cent. of its own weight of unconsumed combustible. As the percentage of ash increases, the percentage of combustible lost in the ash also increases rapidly. With coal containing a high ash percentage, it is rarely possible to reduce the percentage of combustible in the ash to less than 50 per cent. of the weight of the ash.

This reduction in heat value is shown diagrammatically for varying percentages of ash in Fig. 1. The column at the left represents the heating value of ash-free coal, those at the right the relative values for coals containing varying percentages of ash. The upper stratum of each column represents the loss due to the fact that the ash is incombustible. The second stratum shows an additional loss due to the presence of unconsumed combustible contained in the ash taken from boiler grates. The next stratum represents the loss due to the fact that steam boilers cannot be operated at 100 per cent. efficiency. The lowest stratum, therefore, represents the relative commercial values of coal containing varying percentages of ash.

On the basis of Fig. 1, Fig. 2 has been plotted. This shows the pounds of fuel required to produce one boiler horsepower with coal of varying percentages of ash with careful operation. It will be noted that for the best coal with 4 per cent. ash there is required approximately 3 lb. of coal per boiler horsepower-hour, and that with

10 per cent. ash, less than 3½ lb. is required. Beyond this point the increase is rapid until for 21 per cent. ash the coal consumption amounts to 5.45 lb. per boiler horsepower-hour; 80 per cent. more than with 4 per cent. ash and about 60 per cent. more than with 10 per cent. ash.

The increase in the ash content of coal seriously reduces the capacity of steam boilers. The excessive quantity of coal required to deliver a horsepower with poor coal, as shown by Fig. 2, makes it impossible to consume sufficient coal on the grate to deliver the necessary boiler horsepower. Central stations today are in a serious condition because they find that their station load is increasing, but that the quality of coal has much decreased, necessitating the operation of a larger number of boilers. They find that whereas their boiler houses, two or three years ago, were of sufficient size to handle all ordinary increase in power demands, now, because of the poor quality of coal, they provide the steam necessary to carry the station load only with extreme difficulty.

Up to within the past two years it was considered good practice to operate central station boilers at 200 to 250 per cent. of their rated capacity during peak periods. In the same stations it is now difficult to operate the boilers at more than 150 to 160 per cent. of their rating, and sometimes at even less. It is therefore necessary for these stations to place more boilers on the line, and in many cases they have been compelled to purchase additional boiler units at unusually high prices.

This phase of the subject is illustrated in Fig. 3, which shows the number of 500-hp. boilers required to generate 300,000 lb. of steam, equivalent to a peak load of 15,000 to 20,000 kw. With coal containing 6 per cent. ash or less 8 boilers can be made to do this work. If the ash runs higher than 6 per cent. 9 boilers must be operated, above 10 per cent. 11 boilers would be required, and above 18 per cent. 19 or 20 boilers are required. This situation is so bad that practically every large central station today has no spare boiler capacity, unless spare boilers have been purchased and installed within the past two years. They are compelled to refuse new business and must often keep boilers in service that should be undergoing cleaning and furnace repairs.

The effect upon industrial plants is similar to that

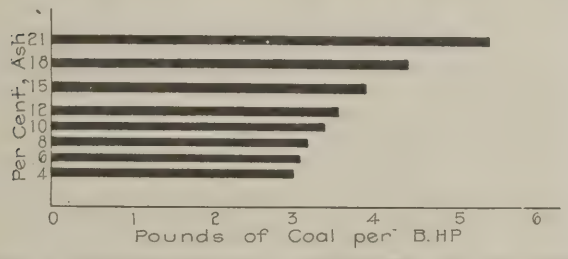

FIG. 2. POUNDS OF COAL CONSUMED TO PRODUCE ONE BOILER-HORSEPOWER

experienced by the central stations, but in a different degree. Industrial plants do not operate their boilers at the high ratings experienced in central station practice, but they do not as a rule carry so large a percentage of spare boiler equipment as do the central stations. They therefore find it necessary to operate their entire boiler equipment, or curtail production, and their boilers are kept in service for longer periods than is good practice. It is impossible to take the boilers out of service long enough to properly clean them from scale and to properly repair baffles and brickwork in the furnaces. The consequence is that the boiler efficiency is seriously reduced until they are in such poor condition that they must be shut down for cleaning, at the expense of production. With reasonably clean coal this situation would not exist.

There is a difference between preventible and nonpreventible noncombustible in coal. The nonpreventible

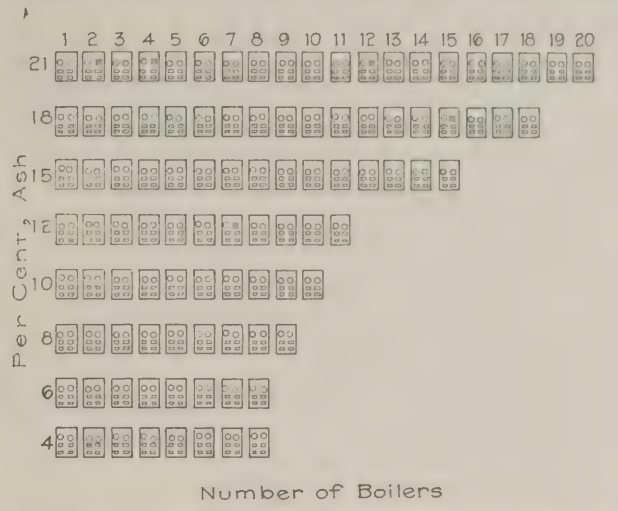

FIG. 3. NUMBER OF 500-HP. BOILERS REQUIRED TO GENERATE 300,000 LB. STEAM PER HOUR

ash is so thoroughly incorporated with the structure of the coal that it cannot be separated mechanically. This minimum ash content differs in each mine.

By preventible ash is meant the slate and other impurities which can be separated by careful preparation. This minimum ash varies from as low as 2 per cent. in some cases to as high as 33 per cent. in other cases. The average for the country is probably about 9 or 10 per cent. The percentage of ash in the coal from various states, together with the output for the year 1915, is given in Table I. Over half the coal mined shows an ash analysis of 9 per cent. or better. The percentage for the country if averaged in proportion to each state's

TABLE I. TONS OF COAL MINED IN 1915 AND THE PER CENT. OF ASH IN THE COAL FROM THE PRINCIPAL COAL PRODUCING STATES

	Coal Mined per Annum Tons (2,000 Lb.)	Average Per Cent. of Unavoidable Ash
Pennsylvania	158,000,000	9
West Virginia	77,000,000	7
Illinois	59,000,000	13
Ohio	22,500,000	10
Kentucky	21,400,000	9
Indiana	17,000,000	11
Alabama	15,000,000	12
Colorado	8,600,000	16
Virginia	8,100,000	8
Iowa	7,600,000	13
Kansas	6,800,000	13
Wyoming	6,500,000	6
Tennessee	5,700,000	15
Other states	29,500,000	12
Average for the country		9.9

production is about 9.9 per cent. We may therefore consider 10 per cent. as a fair average for clean coal for the entire country.

There will be mined this year probably 600 million tons of coal, and 85 per cent. of this coal will be transported by the railroads; hence, for each per cent. above the average 10 per cent. the excess ash will add to the work of the overburdened railroads 5,000,000 tons of useless freight.

Fig. 4 illustrates diagrammatically the increased trans-

portation equipment necessary for handling coal with a high percentage of ash. The number of cars shows the relative number necessary to carry coals of varying degree of ash. The shaded cars represent the percentage of carrying capacity which has heating value, the light cars, the useless freight. It will be noted that in some shipments as much as 40 per cent. of the cars carry worthless material, or in other words coal containing 21 per cent. ash requires 65 per cent. more cars than coal containing 10 per cent. ash.

In all these charts it will be noted that the trouble

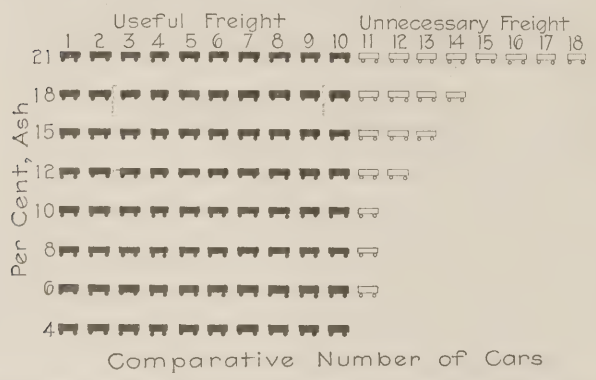

FIG. 4. INCREASED CARS NECESSARY FOR TRANSPORTATION OF HIGH-ASH COAL

from ash is not excessive until we pass 10 to 12 per cent. content. If, therefore, we might limit the percentage of ash to the average of 10 per cent. we would reduce our transportation equipment to a practical minimum; we would be able to operate all boilers at a reasonable efficiency and would reduce the number of boilers operated to a little over one-half of the number required for the dirty coal (that is, 18 per cent. ash or over) besides making a saving in money that cannot be accurately estimated.

Stripping Coal with a Grader

By C. P. Burton
Aurora, Ill.

A method of stripping coal which is rather out of the ordinary, though it is proving successful, is being employed by H. H. McDowell, of Pleasanton, Kan., who is stripping coal for the Star Coal Co., of Kansas City, at Worland, Mo. The removal of overburden from the coal is being accomplished with the aid of a Western elevating grader.

The land to be stripped is a rectangular tract of 80 acres about 700 ft. long. It would be hard to find a more difficult piece of earth-moving for an elevating grader. The average cut in the pit now being stripped is 16½ ft. with a maximum of 21 ft., and the material is tough gumbo and hard shale, overlying 35 in. of coal.

For stripping, Mr. McDowell is using a Western standard elevating grader, drawn by a Reeves tractor, loading into Western 1½-yd. dump wagons, three horses to a wagon. The cut is being made with one side perpendicular and the other, toward the adjoining box pit, with a slope of ½ to 1. He finds eight wagons the proper number for economical work, and under favorable conditions can move from 750 to 800 cu.yd. of material in a 9-hour day.

In his plans Mr. McDowell has divided the remainder of the tract into five box pits about 700 ft. long. The first of these pits, now being stripped, is 72 ft. wide at the top and 60 ft. at the bottom. The next pit has a bottom 40 ft. wide; the third, 75 ft.; the fourth, 40 ft., and the last, running to the edge of the property under lease, is 60 ft. wide.

These five box pits will not be stripped in continuous succession but alternately, the two inside pits, each 40 ft. wide at the bottom and 700 ft. long, being left until the last. When he comes to strip the two inside pits, by using a longer elevator on his machine he expects to be able to cast fully two-thirds of the material. This will be an inexpensive operation and will reduce his yardage cost materially.

Legal Department

Dangerous Places of Work.—The general rule of law that an employer is bound to use a reasonable degree of care to provide his workmen with reasonably safe places of work has no application to classes of work consisting in making a dangerous condition safe, as where a mine timberman undertakes to reset timbers which have been knocked down by a runaway coal-cutting machine and is injured by a fall of slate while replacing a prop. (Kentucky Court of Appeals, Charles vs. Elkhorn Mining Co., 200 Southwestern Reporter, 461.)

Taxation of Coal Lessee's Interest.—An instrument granting the right to mine coal underlying land within a specified period and providing for the payment of semi-annual royalties conveys a taxable interest in the real estate, under the laws of Illinois, and not a mere license. By express provision of an Illinois statute the right to mine may be conveyed by deed or lease, and such conveyance is to be regarded as so separating such right from the land as to make it separately taxable. (Illinois Supreme Court, Simmons Coal Co. vs. Board of Review of Fulton County, 118 Northeastern Reporter, 753.)

Negligence of Mine Foreman—A Pennsylvania coal-mining company was not liable for injury to a miner resulting from a fall of slate from the roof of a passageway being constructed under the supervision of the mine foreman, where the company had no knowledge as to the existence of the defective condition of the roof and that condition had not existed long enough to charge the company with constructive notice of it, although the mine foreman's attention had been called to the fact that the place was unsafe and he failed to remedy it or to provide warnings against it. The mine foreman being given full charge of the inside workings under the Pennsylvania Bituminous Coal Mine Act of June 11, 1911, the operator is not liable for negligence in the performance of the foreman's statutory duties. (Pennsylvania Supreme Court, Cossette vs. Paulton Coal Mining Co., 103 Atlantic Reporter, 346.)

Liability for Injury Caused by Roof Fall.—If plaintiff, who was injured through fall of rock from a roof under which his duties required him to pass, was a foreman in charge of the work at the particular place, with full authority and charged with the duty of doing all things necessary to make the place reasonably safe, by timbering or by removing loose earth, he is not entitled to recover. But if, as claimed by him, he was merely a timekeeper, and it was the duty of other employees to look after the safety of the mine, and to remove all obstructions and dangerous elements, than he is entitled to recover damages to cover any injury arising through failure of the defendant operator to provide him with a reasonably safe place in which to work. (Oklahoma Supreme Court, Sandals vs. Mizpah Mining Co., 168 Pacific Reporter, 808.)

The Coal Industry's Part in the War

BY GOVERNOR JOHN J. CORNWELL
Charleston, W. Va.

SYNOPSIS — *Substance of an address delivered by the Governor of the State of West Virginia at a large meeting held at White Sulphur Springs, W. Va., on Sept. 15, for the purpose of stimulating coal production.*

IN THE incipient stages of our war preparation the fuel situation had not become acute and, indeed, on the surface there was no indication that it would become so acute as we found during the winter months that followed. Up to a short time before that the coal market was running wild and was uncontrolled. Just immediately prior to that the price had been fixed by the President, and there was no little dissatisfaction manifested among some of our people, either openly or quietly. The seriousness of the war situation had not then dawned upon the majority of our people, nor had they got a glimpse of what tremendous efforts our Government and our people were to make to bring this war to an end.

Many people thought all we would do in this war, at that time, would be to loan some money to the Allies and furnish them supplies. Others thought we would go further and send our fleet abroad, but despite the fact that our first registration had occurred in June, and at that time the great cantonments were being completed and arrangements were already on foot to take into them the first increment of the selective army, notwithstanding all this there were few people, indeed, who imagined that within one year from that date we would have in France nearly two million soldiers; that we would have there the biggest port in all Europe for our exclusive use, a port built and established with American men, American material and planned by American engineers. Nor did they imagine that we would have built, within one year from that, more than 600 miles of double-track standard-gage railroad over there; that 2000 of our big locomotives would be operating on that railroad and that 40,000 American railroad men would be astounding the European people with their energy and their skill in operating and maintaining the railroad. Nor did they see that more than 150 great shipyards, reaching all the way from Portland, Ore., and Seattle, Wash., clear around to Portland, Maine, would be dropping ships into the water every few moments at the end of that year.

ASTOUNDING RECORD MADE IN SHORT TIME

But all these things have come to pass in one short year. Today we see and know two things: First, that the accomplishments of the past eighteen months are record-breaking. No country under the shining sun ever made such stupendous preparation in so short a time. In fact never before in the history of the world did any country attempt to fight a war on such a large scale 2500 miles from its base of supplies. That this country is not only well along in its preparation but that it is actually a factor, and a very great factor, in the struggle, the story of the fighting over there that comes to us day by day fully attests.

Our preparation has been an achievement of which the country may be proud, despite some mistakes which are inevitable always under such conditions; but the valor, the courage, the dash and the tenacity of our soldiers in France constitute and will continue to make a record superb, glorious and imperishable, of which every American will be proud as long as he lives.

ONLY THOUGHT NOW IS TO WIN THE WAR

Today we understand much better the task that lies ahead of us than we did in July, 1917. Our attitude is quite different than it was at that time, when many coal operators deeply resented the Government's interference in the price of coal, believing that they should be left to sell coal for all they could get and ship it wherever they pleased. Today we realize that monetary profit is a subordinate, a really inconsequential thing, except as it may enable one to give financial support as well as support in the way of furnishing coal and other material.

I doubt whether all of you even now comprehend the danger that confronts the country the coming winter from the fuel standpoint. It may just as well be understood that if there is not enough fuel to keep all the factories and all the mills going (and it is certain that there will not be), that the Government must and will close all those that are not absolutely essential to the support of the war program. Indeed in this crisis no man has any right, any moral or legal right, to go on using men and consuming fuel and material manufacturing luxuries and non-essentials. The country must be placed on a strictly war basis, and while that is going to cause inconvenience, cause embarrassment and perhaps cause loss to some people, it is inevitable. We can't win this war even now with part of our people working at it and the rest of the people grabbing for labor and material to make non-essentials for profit. So the Government will determine—must determine—who is to consume your coal.

What does a shortage of coal mean to the Government? What does it mean to our Army? What does it mean to our boys from West Virginia who are over on the firing line in France? It means the Government will not be able to get all the ammunition over to Pershing and to our boys which they need, and if we are short of ammunition it means a greater loss of life. To repeat the language of a prominent speaker: "From now on it is munitions against casualties. If you keep this in mind, you will have the background for the sternly drastic attitude of the Government during the next six months in clearing the way for filling Pershing's orders.

"We are facing a catastrophe. It is not one of those catastrophes which make such a noise that every one knows when it happens. It is a silent tragedy. We can not fill Pershing's orders in full, because the United

States can not make sufficient steel this winter. A shortage in steel results almost entirely from lack of coal. Keep this in mind and then look forward to the events of the coming spring. We shall have the drive. We shall succeed, but some time in February or March, or whenever the time has come, General Pershing will sit down with a pencil in hand, will figure up the exact deficit in the filling of his orders for munitions.

"With military formulas now well recognized he will figure in place of those munitions how many extra men must be put into the battle to be killed. This is no fanciful statement. It is now possible to treat the question of munitions or of casualties as interchangeable quantities. So many thousand American youths must be thrown into the hopper for every thousand tons of munitions which are short."

Why Coal Production Must Be Speeded Up

My God, men! What an awful thought that is! Do you get it? Can you grasp that thought and carry it back to the men in the mines and get them to realize that we are already short of coal; get them to realize that that shortage of coal will prevent our Government from filling Pershing's orders for shells and bombs and hand grenades; get them to realize that in place of that ammunition and these shells the Government can't supply, more men, more boys must be put into the army to be killed—all because we have not produced enough coal? Can you bring the men who dig the coal to understand this and to realize the seriousness of it?

If the West Virginia miners only understand these things I know they will dig and load coal as they never did before, for they will be working to save the lives of their own sons. The man who would not work longer and harder under these circumstances does not deserve to be called a man.

Most, if not all of you, I take it, come from the fields that produce the smokeless coals, coals used by the Government itself direct on its ships. When the Government clamors for more coal and asks for the speeding up of production, some of your employees and some of you may wonder where they take all the coal you give them and what they are doing with it.

Well, when one knows the increased number of naval vessels that consume it, that is easily understood. The story of the extension of our navy is not being widely told, but it is an amazing story. From some 50,000 men in the American navy when the war began the force has expanded to more than 600,000. From 250 fighting ships of all classes it has expanded to more than 2000. The Navy Department is building right now more destroyers than there were in all of the fleets of the world when this war began. In 28 days after the declaration of war our speedier ships reported for duty alongside with the English ships in the North Sea, and they circle the waters of Germany by the hundred. So the demand of the navy for coal is tenfeld what it was when war began. Then in addition to that the Government itself is producing a merchant fleet at an unprecedented rate.

I know there was much delay, apparently, much discussion and no little criticism of the fleet program—I mean the merchant fleet program—in the beginning. But you know what is going on now. American shipyards are producing tonnage faster than England, though England lives by ships and has been the great maritime and the great shipbuilding country of the world. We have already outstripped her. The new merchant ships need coal and they must have it, otherwise it were better they had never been constructed. Your smokeless coals, therefore, are absolutely essential and directly or indirectly essential to the Government's program.

And the demand will increase. It is going to get greater and greater. Every little while a new battleship or a new destroyer is placed in commission. Every few minutes a new merchant ship slides down the ways, takes to the water and is quickly fitted up and commissioned. That must go on and on, for if the German machine does not crack and crack and break in the meantime, one year from now instead of having a million and three quarters of men in France we will have an army of four or five million men over there.

To take them over, sustain them and supply them, our merchant fleet must be more than doubled. When that happens the demand upon you for coal will be doubled, at least be very greatly increased. Of course, many of these new vessels are fitted up as oil burners. Every effort is being made to relieve the pressure as much as possible upon the coal men, but that pressure will get heavier and heavier.

Now, how are you going to meet it? Operators have said to me, "How can I produce more coal when you are taking men out of my mines for the army?" I am not unappreciative of your problems. I am not unaware that you have a very difficult one, but it is unquestionably true that all kinds of production can be greatly increased by speeding up, if all the people can be made to realize that that is necessary. Canada gave an illustration of what can be done in a crisis. Canada sent 600,000 men to England, financed the expedition and loaned money to the mother country in the bargain, and then the Canadian people at home turned to and produced 25 per cent. more than ever before. When Canada sent 600,000 men overseas, that is equivalent to this country sending 9,000,000 men. To equal Canada's effort we should send 9,000,000 men to Europe and then increase our production 25 per cent. Are we capable of doing it?

Patience and Precept Absolutely Necessary

It is true that Canada's production was largely agricultural and that the men on the farms and in the vast wheat fields were not hampered with an eight-hour day contract. But my thought is that you men who own and operate these coal mines can do a great deal toward impressing upon the men who dig and load coal the seriousness of this situation, and can do a great deal toward inspiring them to make whatever sacrifice may be necessary to meet it. I realize that you can not do that by merely issuing orders. I realize that you will have some unreasonable people to contend with and some stubborn and vexatious cases to handle. But there are two things that will go a long way toward getting the desired result. The first is patience, infinite patience. The second is a good example.

The superintendent or the mine boss who has all the patience of Job, who will keep sweet all the time and be reasonable, having regard for the rights and feelings

of other people, for the men who work, that man can get results, I believe. If he will speed himself up and double his own efforts, that too will, in my judgment, have a good effect. A good example is the best of all teachers.

We have heard a great deal about the shortage of labor during the past year. As a couple more million men are drawn into the army we will necessarily hear a great deal more about it. The labor shortage would have been greatly relieved at any time within the past year and would be greatly relieved now, were labor stabilized. The turnover in labor has been something tremendous.

The payment of high wages at ammunition plants and other places where there were rush jobs have attracted labor from normal employment. The unsatisfactory living conditions cause many of the men to leave the job which they had traveled a long way to obtain. Fully 20 per cent. of the labor of the country has been continuously and perpetually riding on railroad trains or shifting about from place to place. While that has not been true in the coal fields to the same extent, it has had its effect there, I am quite sure.

There are several reasons to hope that this part of the trouble will be gradually eliminated. First, the Government has established its labor bureaus and is gradually eliminating the private employment agencies which were encouraging the shifting of men from one plant or place to another. Second, with the completion of the construction of a great many plants and the putting of them into operation, thousands of men will be released. Third, the closing of plants of non-essential character, which is inevitable. Fourth, the increased number of women who will take positions in many industries and factories of the men who will go into the army or take up work which a women can not do.

Good Living Conditions Essential

But there is something the employer can do to stabilize labor, something many of them have already done, those who are holding their labor. That is, to make the living conditions just as tolerable as is possible; make them not only tolerable but attractive, so that if a man has a family he will be willing to continue to reside there and raise that family with an opportunity to educate his children and live amid attractive surroundings. Therefore, should not the operators and the state join hands in working out a program for the future where the health and the happiness of the worker are subjects of especial attention?

In the years that have gone the coal operator had a harder time to find a market for his coal at a profitable price than he had to find men to dig the coal. The West Virginia operator has had a peculiarly hard lot. Notwithstanding he had the best coal in the world, he has been discriminated against by railroad differentials and has been unfortunate, too, because the operators of other fields have been able, through their more active or more unscrupulous press agents and congressional representatives, to put the West Virginia operator in an unfavorable light before the public. Therefore you have had your handicaps to bear and you entered this war under very unfavorable conditions. Your vigorous and patriotic support of the Government and your cheerful acquiescence in every regulation has, however, put you on a new footing before your fellow citizens and before the officials of your Government.

This war has cast a tremendous responsibility upon you which you are meeting in a patriotic way. You will not be able to perform miracles, but by patience, through energy, through diplomacy and through a willingness to match the sacrifices of the men on the other side of the water, you will meet the situation as far as human effort and human ingenuity can meet it. The country's demand and its need for coal is unbounded and will continue to be during the war. There will simply be no limit to it. On the other hand, the limit of production of steel and of munitions and supplies for our army will be the limit placed by the amount of coal that can be produced.

Today there is but one thing before us—*win the war,* save the lives of as many of our men as possible and get them home as soon as possible. Of the vast army at home none in it can do more to speed up that great day when our boys return triumphant than the coal operators and the coal miners. Stop the supply of coal and disaster will befall our army. With that situation confronting you we have a right to expect every coal man to do his duty.

Generation of Electrical Energy

Much confusion exists about the term "generation of electrical energy." Strictly speaking, this expression is incorrect because "energy" can neither be created nor destroyed. Energy, as defined technically, means capacity or ability to do work. There is a certain definite amount of energy in the universe and this total amount can be neither increased nor decreased.

Hence, when one speaks of the "generation of energy," what he really means is the transformation of energy. Thus, while energy cannot be generated, it can be changed from one form into another. The energy of a stream of water can be transformed into electrical energy by the application of a waterwheel and a dynamo. But the latter machine has not created electrical energy; it has, due to the assistance of the waterwheel, merely changed the kinetic energy of the falling water into electrical energy.

Now consider the generation of energy from coal. The energy in coal is due to heat transmitted to it by the sun centuries ago, and which has been stored up in this material ever since. Now when this coal is burned under a boiler, heat energy is derived which is transferred to the water in the boiler. Thus steam is generated. Considerable of this heat energy is wasted through radiation losses, losses up the stack, and by condensation.

Next the heat energy in the steam is carried to the engine or turbine. In this machine this heat is transformed into mechanical energy. Then in the electric generator, which the engine or turbine drives, the mechanical energy is again transformed, but this time into electrical energy. Finally, the electrical energy is again transformed into heat energy, within some electric-lighting device, in the conductors which carry the electric current, or by friction of some sort or other. Or it is changed into mechanical energy through the medium of electric motors.

Summary of Traffic Conditions

A Fuel Administration summary of the traffic situation is as follows:

"Eastern Region—Coal car shortage in Ohio due to scarcity of power, which is being corrected. The regular car supply at some other points now having the attention of the Car Service Section. Some coal congestion in New England, both water and all-rail, due to lack of unloading facilities.

"Tidewater—Vessel supply more than ample; transportation conditions good.

"Lake Situation—Vessel supply interfered with by storms and ample coal at docks.

Coke—Car supply good. Shortage of labor limiting production, especially in the South.

The Navy Department's report says: "Coal supply better than had been stated and indications are that the Department is starting winter months with better protection in regard to supplies on hand than last year."

Shows Unjust Discrimination in Coal Mining Industry

Unjust discrimination between competitors within the coal mining industry by the present revenue law are set out clearly in a tabulation submitted to the Senate Finance Committee by Rush C. Butler, general counsel for the National Coal Association. The tabulation, which shows the capital of the reporting companies per ton of annual production, based upon the returns made to the Treasury Department, is as follows:

	Companies Reporting			Capitalization per Ton Produced			
Capital per Ton Production	Number	Per Cent. of Total	Their per Cent. of the Production Reported	Low	High	Average	Exemption on Basis of 10 per Cent. of Capitalization
Under $1.....	41	10.38	19.6	$0.047	$0.963	$0.65	$0.065
Between $1 and $2.	156	39.49	27.6	1.022	1.968	1.43	.143
Between $2 and $3.	105	26.58	21.9	2.00	2.957	2.14	.214
Between $3 and $4.	34	8.61	6.3	3.072	3.979	3.46	.346
Between $4 and $5.	25	6.33	13.8	4.21	4.887	4.65	.465
Over $5.....	34	8.61	10.8	5.04	13.93	8.21	.821
Total.....	395	100.00	100.0	.....	.....	$2.72	.....

Capitalization of companies in first three groups, representing 69.14 per cent. of production, is $1.42 per ton.

Capitalization of companies in last three groups, representing 30.86 per cent. of production, is $5.88 per ton.

Companies reporting produce 143,894,309 tons.

Mr. Butler also brought out the following points: "The reasons for an extraordinary exemption on the mining industry are numerous, but two will suffice at the present time: First, because the mining industry is extra-hazardous and only invites capital that is willing to take extra chances, which, in turn, is entitled to a larger percentage of profit; and, second, the extra exemption should be allowed for the coal industry, because of the fact that the coal industry pays a higher percentage of its net profits by way of a Federal tax than any other industry. I cannot make this statement, however, authoritatively, but I have been so advised by representatives of the Treasury Department. It would, therefore, seem that if all industries are to be on a comparative basis, there is just occasion for the Treasury Department's recommendation that a special exemption applicable to the mining industry be made."

A brief signed by J. H. Wheelwright and J. D. A. Morrow, president and secretary respectively of the National Coal Association, and by its committee on Revenue Legislation, has been submitted to the Senate Committee on Finance. The brief covers: (1) A proposed revision of the definition of invested capital; (2) a proposal that borrowed capital be not excluded from invested capital; (3) a proposal that the excess of current cost over and above prewar cost of installations of plant, equipment, etc., be amortized at the rate of 50 per cent. per annum for a two-year period.

The brief also urges the favorable consideration of the Treasury Department's recommendation, which is referred to above by Mr. Butler, for the following reason: First, that the coal industry is said to have paid a higher percentage of its net income by way of Federal taxes for the year 1917 than any other industry, thus clearly indicating that the coal industry as an industry carried more than its share of the burden of Federal taxation; second, that the hazards of the business are relatively much greater than the hazards incident to almost any other industry.

Berwind-White Co. Receives License

The settlement of the license question with the Berwind-White Coal Mining Co. is the subject of the following announcement by the Fuel Administration:

Owing to the fact that a vast majority of the coal sold by the Berwind-White Coal Mining Co. is produced by that company itself, or by companies which it controls, it was under the impression that it was not required to obtain a distributor's license under the President's proclamation of Mar. 15, 1918. When the company's attention was called to the fact that under such proclamation licenses were required by all companies which distributed any coal whatever which was not produced by themselves, it promptly applied for a license.

After a full investigation this license has now been granted, upon condition, however, that the company refrain from charging any purchasing agent's commissions on any coal distributed by it prior to the date on which such license is granted, and the company is preparing reports of all coal, other than that produced in its own mines, which it has distributed since Apr. 1, 1918, so that its distribution business may be subject to the same control regulation and investigation that it would have been if the company had applied for and obtained a license on that date.

Would Ship American Coal to Italy

Great Britain will be unable to furnish Italy with as much coal this winter as was the case last winter, according to information presented to the Senate by Senator Owen of Oklahoma. The fuel situation in that country is represented to be so desperate that Senator Owen urged, on the floor of the Senate, that coal be sent from this country.

Must Have Larger Coke Output

Coke production in the United States must be increased at once by a minimum of 30,000 tons a week if the war program of the Government is to be carried out. A greater increase is desirable, and may soon be needed, but the call for 30,000 tons more each week is immediate and insistent. It is a literal fact that failure to supply this increase is going to be paid for in American lives in the big drive of the allied armies against the Germans.

According to figures given by W. S. Blauvelt, Director of the Bureau of Coke, United States Fuel Administration, the coke capacity of the United States is 1,350,000 tons weekly. Production is running at approximately 1,170,000 tons weekly and the minimum requirement is 1,200,000 tons weekly. Chief among the factors of the shortage is the labor situation in the coke yards, to which is ascribed three-quarters of the deficit.

More labor is needed, and 100 per cent. efficiency from the labor now employed is likewise required to meet the situation. Operators in the Connellsville field, at a recent meeting, adopted a resolution that "furnaces shall not bank" for lack of Connellsville coal and coke. This has been followed by a general appeal to coke workers throughout the country, by means of pay envelope folders, to make this resolution apply to every coke oven in the United States.

Labor is short in many coke yards, and in some places it is only by the voluntary exertions of other workers that coke can be loaded at anything like capacity. An instance of this occurred recently at the yards of the Wisconsin Steel Co., in Benham, Ky., where about 200 men engaged in other lines volunteered for work one Saturday evening and loaded about 1000 tons.

In other cases there is failure to load at anything like capacity because full-time service is not being given. It is hoped to impress workers, in such cases, with their patriotic duty to work steadily every week, just as it is hoped to recruit men for the depleted payrolls in other yards.

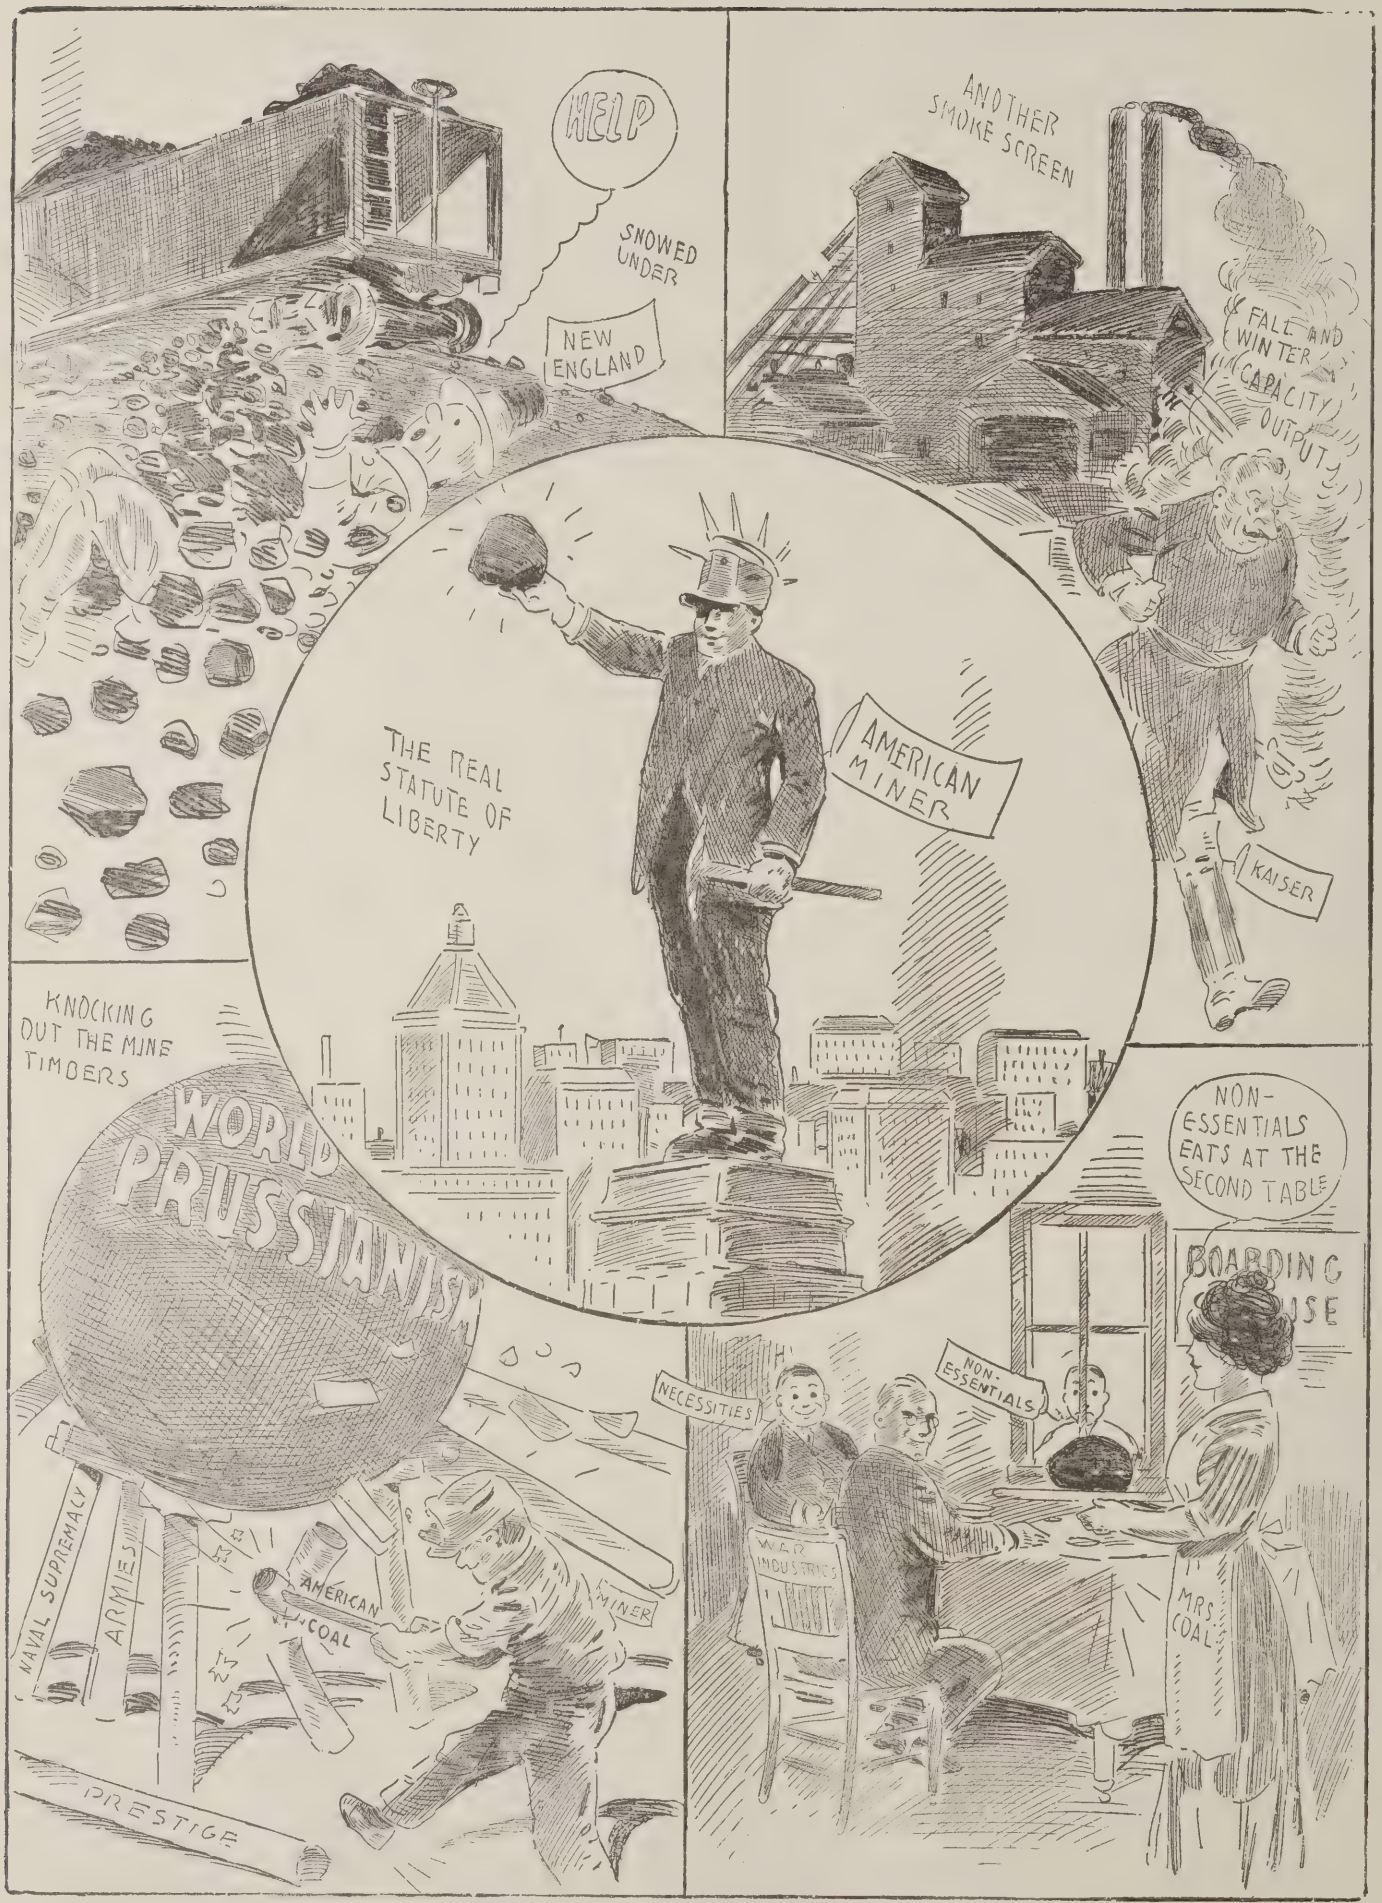
The importance of larger coke production, and the patriotic obligation resting upon every coke worker, are to be driven home wherever possible. The facts in the coke situation speak for themselves. It is a simple truth to say that more good coke means more steel, more shells and fewer casualties. Iron depends upon coke, which is another way of saying that the shells and guns, the helmets and bombs used by our soldiers depend upon a steady and ample supply of coke. So do the ships to carry these supplies abroad and so do the rails and locomotives which carry the supplies across France to the battle front.

In the case of byproduct coke, there are additional essentials which depend upon large and continuous output, for byproduct ovens supply the bulk of the explosive material used in American shells, in addition to tar for surfacing military roads or the roofing of military buildings, and the bases for many medicines and disinfectants used in tremendous quantities in military hospitals.

High Output in Kentucky, Tennessee and Georgia

For the second week in succession bituminous coal production was broken in the Harlan field of Kentucky, Tennessee and Georgia during the week ended Sept. 21, according to a report received by James B. Neale, Director of Production, U. S. Fuel Administration, from Howell J. Davis, Production Manager for the district. Output during that week was 338,820 tons, an increase of 10,286 tons over the previous week, when the record was 328,534 tons. This latter figure was itself a record, the previous high mark for the coal year having been 306,941 tons.

Garfield Appoints Director of Education



Fuel Administrator H. A. Garfield, on Oct. 3, appointed C. E. Persons, of San Francisco, Director of Education of the Fuel Administration. Mr. Persons has been connected with the Western Division of the Associated Press for seven years, and for the last three years has been news editor of that division. At the request of Dr. Garfield, the Associated Press has released Mr. Persons for this work.

No exception to the lightless night order is to be made during the Liberty Loan drive, the Fuel Administrator has ruled.

James H. Allport has been made a member of the license board of the Fuel Administration. He succeeds Noah H. Swayne, 2d, resigned.

C. C. Anderson, of Boise, Idaho, has been appointed fuel administrator for his state. He succeeds Frank R. Gooding, who has resigned to enter the race for the United States senatorship.

Mechanical labor-saving devices relating to mining are to be studied intensively by a committee consisting of S. A. Taylor, of the Fuel Administration, and George J. Salmon, of the Bureau of Mines, and Grant Hamilton, of the Department of Labor.

How the High Lights in the Coal Situation Strike the Cartoonist

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

Up to the present no revision has been made in the mine labor scales of the anthracite region, but it is likely that action will be taken soon. It must be remembered that coal mining is a permanent industry whereas the munitions industries, using that expression in its broad sense, are in part temporary. Is the large price paid to the munitions workers for war service to be duplicated in the mining fields for an indefinite period? It would seem that if we are going to let a permanent industry enrich itself by such wages the increase should be distinctly of the nature of a bonus and not a permanent increase.

All excessively high wages can be maintained only by an unfair restraint of trade and can only be kept of value by preventing, after the war, a flood of labor from other industries; for a high wage and no chance to work is clearly of no value to anyone. Clearly any attempt to keep others out of any industry is unfair and undesirable. It is going back to the old order of things, the medieval order. Certain people will be "free," as in ancient time, to enter the "mistery" of mining because their fathers or their wives' fathers were in the business. Or else the "freedom" will be for sale and we will have the miner occupying the position of the "liverymen" of a feudal city. All who pay certain large dues to the union will be permitted to enter it, and all who refuse will have to keep clear of the mines This is the inevitable result of keeping the wage rate higher in one industry than in another, as has been amply proved in the window-glass industry.

MAY READILY RE-ESTABLISH LABOR AUTOCRACIES

Freemen or liverymen, or whatever you may call them, are merely memories or functionless survivals of a dead past. They represent, however, an evil principle that can easily be reëstablished if the possibility is not watched. The public does not want the right to work in any industry restricted by anyone. Nor does it want to see wages reduced after the war, and for that reason it does not desire to see the wages in permanent industries boosted above the market value of labor.

Several men in the Gallitzin region of central Pennsylvania, all miners, have been arrested for continued drunkenness. Every miner will be glad to see that pressure is being brought to bear on these men who discredit miners as a class and the industry as a whole. Each payday these men, numbering about 20, would "go on a drunk" and remain idle for several days—idle when their country called for their services and men at the front were not getting the support needed for speedy victory at minimum cost.

ARRESTED MINERS FOR CONTINUOUS DEBAUCHES

The men seized were mostly employees of the Taylor & McCoy Coal Co. of Gallitzin and were arrested, at the suggestion of the company, by Chief of Police Lees and Railroad Officer Schlosser. The Gallitzin miners are of all countries, Americans, Russians and Austrians predominating. The report does not say anything as to the nationality of those arrested.

The Spanish influenza is stopping all meetings in Pennsylvania and consequently preventing those important sessions at which the miners are urged to speed production. The health authorities believe it is more important to output that men should be kept in health than that they should receive the patriotic stimulus these meetings afford.

There is still trouble in western Pennsylvania with the overenthuiasm of some of the officers of the draft, where doubtless it is hard to fill the quota without depleting some of the many essential industries of the district. R. W. Gardner, the manager of production for the Pittsburgh district, states that several local draft boards are exceeding their authority by placing coal miners in class 1.

He says that he is about to appeal to district draft boards to give such men deferred classification and that, if necessary, he will carry the matter to the highest authorities. He adds that there is a loss of 18 to 20 per cent. in coal production by reason of the frequency with which miners lay off work, sometimes for periods of two or three days in one week.

WANT PRESIDENT TO MAKE POINT MARION DRY

Point Marion is still a sore spot with the operators in the Monongalia field of West Virginia, in which area should be included the Scotts Run section. After payday several miners of this part of West Virginia leave the state for Point Marion, Penn., and for some time thereafter they spend their earnings in riotous living. The University of West Virginia authorities, who have large numbers of soldiers in training, are prepared to combine with the operators in demanding a closing of the saloons at Point Marion, but not because there has been any trouble with the soldiers, as these good fellows stick closely to their studies and need no legislation to keep them in due restraint.

The Point Marion liquor dealers are said to be making big money out of their traffic, as much as $10 a quart being charged for whiskey. The President has full power to take the alcoholic sting out of the Point Marion scorpion and it is to be hoped he will do it.

In the Winding Gulf district the spirit of whole-hearted Americanism is to be found at its best. A Baptist minister, the Rev. Dr. Coleman, has even entered the mines to load coal, urging upon himself that we should be "doers of the Word and not hearers only." Dr. Coleman is certainly "some doer." He loaded 12½ tons the first night and the next night, instead of decreasing his efforts, he loaded out two tons more. He says he not only wants to supply coal for the Navy but to feel "just as his parishioners feel after a hard day's work."

TO BUILD A FIRE TO BURN DESPOTISM TO ASHES

The Right Rev. P. J. Donahue, Roman Catholic Bishop of Wheeling, has issued a summons to all the mining members of his diocese to produce coal as "true men and patriots." He says: "Your country calls you as never before. Coal is king. You are his willing subjects. Today he is the greatest power of all. I believe that, in the Providence of God, our beloved land is now the divinely appointed agent to keep the torch of Liberty flaming brightly amid the terror and the horror and the blackness spread like a pall over the face of the earth. We, the heirs of freedom, are freedom's last hope."

He then urges them that "every additional ton will build a fire to burn despotism to ashes. Every car you load helps to hasten the death knell of Kaiserism." The Bishop calls on foreign miners to eliminate the celebration of holidays and requests the clergy to actively use their influence to increase the coal output.

Illinois is deeply interested in the Fourth Liberty Bond campaign. The union has voted to buy $500,000 worth of bonds, where it will be done not being as yet decided. The miners having done this collectively, are determined to do as well individually. A subscription of $100 per member is the goal set by the union leaders of that state, and Patrick F. Murphy, chairman of the committee on coal and labor organizations in Sangamon County, announces that several unions have already made their quota on that basis within

the area over which he has worked. In the Third Liberty Loan campaign, 100 per cent. subscription was sought, but most of the subscribers took a $50 bond.

The miners at Duquoin, Ill., have promised that they will not strike so long as the war lasts, making the vow with raised hands at a mass meeting, at which C. M. Coleman, a sapper of the Canadian Army, who had served 26 months on the western front, spoke. He told them that every 80 lb. of coal was equivalent to a 16-in. shell.

The meeting was held at the close of the session of the Southern Illinois Mine Superintendents' Association, Dr. H. C. Honnold, of Chicago, the head of the Illinois division of the United States Fuel Administration, being present.

Now that the Government has taken over the Moffatt road in Colorado, the miners of the Routt County coal fields are flocking back, because they feel assured that there will be work through the winter, and all the mines will be operated to capacity. There seemed to be a question whether under private management the road would be kept open during the severe winter months.

The troubles in Canada seem drawing to an end, though in British Columbia the outcome has been a subversal of authority under which the miners' fiat becomes law. A commission should have determined what course should have been adopted in the operation of the mines.

The Department of Labor is trying to round up all the former members of the coal industry who have drifted to less important occupations. They will ask them for the country's sake to get back into the harness. A circular letter has been sent to all the 3500 locals of the United Mine Workers by Director General Densmore. The campaign is being handled by the Mining Division of the United States Employment Service, consisting of James Lord, the president of the Mining Department of the Federation of Labor; E. B. Chase, general manager of the Berwind-White Coal Mining Co., of Philadelphia, Penn.; and William Diamond, former statistician of the United Mine Workers.

The Spirit That Will Win the War

Everywhere there has been a shortage of men to handle the coke at beehive ovens. It has been necessary at the mines of the United States Coal and Coke Co. in Gary, W. Va., to bank several ovens for this reason alone. In Connellsville, Penn., the matter has been almost equally difficult to solve. Imitating the French declaration at Verdun, "*On ne passe*," They shall not pass, the Connellsville coke operators have proposed the slogan, "They shall not bank," in reference to the iron and steel furnaces which are operated on the coke that has made Connellsville famous.

In every pay envelope appears an enclosure running: "*Furnaces shall not bank* for lack of coke—then *our soldiers shall not die* for lack of guns and shells."

From Benham, Harlan County, Kentucky, we hear that the Wisconsin Steel Co. has been wrestling with this trouble. It was solved by the simple expedient of requesting all employees to load coke on one Saturday night, Sept. 21. The solution was practical and successful by reason of the admirably patriotic sentiment of the men employed. The photograph shows how many responded. There is no indifference evidently in the little town of Benham.

The village has more than 400 coke ovens and the product they make is essential to the operations of the Wisconsin Steel Co., at Chicago, Ill. Owing to the number of men who have entered the service, it is hard to get the full coke tonnage, without employing men who are engaged normally at other work. The men who volunteered on that memorable Saturday were, during the day, miners, machine men, motormen, couplers, trackmen, pumpmen, machinists, carpenters, officemen, engineers and foremen. The list of occupations as given should be extended if accuracy is sought, for every employee who could handle a fork was crowding the coke piles and working like a man possessed.

Entering into the spirit of military service, the men before going to the ovens formed in parade and were led by the Benham white and colored brass bands. They marched to the coke yard 200 strong and loaded more than 1000 tons of coke. The ladies of Benham and the Benham Boy Scouts, Troop No. 1—for it was a community effort and the women and boys formed an important part—provided sandwiches and coffee.

"This is," says F. B. Dunbar, the proud superintendent, "the same patriotic crowd who subscribed $700 in the first Red Cross drive, $2500 in the second Red Cross drive and purchased $38,000 of Liberty Bonds. They also have organized a war chest and each employee pays from 5c. to 10c. per day into the war fund, which is to be equally divided between the Red Cross and the Red Triangle. Each family in this town receives monthly the Red Cross magazine and also the *Association Men*, which is published by the Y. M. C. A. We have a service flag with more than 100 stars. This is the spirit that will win the war. We are proud of Benham."

THE FURNACES AT CHICAGO NEEDED COKE, THESE MEN FROM THE BENHAM COAL MINES WENT OUT ON SATURDAY

Secretary Wilson on a Wage Increase

Early in September when the question of increasing wages for the anthracite mine workers was agitated Fuel Administrator H. A. Garfield wrote to Frank J. Hayes, president of the United Mine Workers of America, as follows:

"While I find it impossible to go to the President with a request that wages be raised contrary to the spirit and understanding of the promise made to him last October, I have not hesitated from the beginning to say that I shall give careful heed to the investigation now under way by the Department of Labor of the cost of living and of the relative wages paid in all fields of industry. The principle of equalization of wages between mine workers and the workers in other fields to which you call attention is sound. It is also reasonable and right that account should be taken by me of the findings of the Labor Department Committee."

Secretary W. B. Wilson wrote to Dr. Garfield as follows:

"At the conference last night with the representatives of the anthracite miners and yourself, I made the following statement and suggestion:

"'A lifetime in the labor movement, keen observation of its ups and downs, has led me to the conclusion that the greatest asset that the labor movement has—the one thing that has gradually brought it to be a power in our country and in other countries of the world—has been its recognition of the obligation of its contracts. Whenever a contract is made for a given period of time, whether that contract be good or bad, the labor movement is strengthened if its members religiously live up to its terms. I know of no other one thing that has done as much to make the United Mine Workers of America the power in the mine industry that it is today as the fact that it has stood by its contracts.

"'Once those contracts have been made they have been lived up to, and that has been done sometimes when it meant serious discomfort to do so, especially at times when the very fact that the union was living up to its contracts was used as a weapon to defeat certain portions of its membership. In face of that kind of record and the benefits that have accrued from it I feel with Dr. Garfield that you should religiously live up to the agreement and promises entered into even if the only basis for this course was the material benefits that would come from so doing. But a higher, greater, better benefit, the spiritual benefit, comes from a knowledge of a duty properly performed.

"'Now although this is true and you have made a contract and made promises in connection with the contract there still remains the significant fact that there is seemingly a sufficient discrepancy between the wages that are paid to you and the wages that are paid to those engaged in munition manufacturers and in bituminous mining to induce a movement from your mines to these other industries such as will be injurious to the country in view of the difficulties it is now giving. That is a condition that the whole country is interested in correcting.

"'In correcting it, however, we ought to have a care not to create a condition that would reverse the process and create an undue drift from other industries into yours.

"'At the desire of the President and to secure more stable conditions in industry we have built up within a week or so a board, the title of which has not yet been decided upon. I presume it will be looked upon and considered possibly as a general wage board. It is a board that is to be composed of two representatives from each of the wage adjustment boards that have been created by the Federal Government. The purpose of that board is to review the contracts or proposed wage adjustments that may be arrived at by any one of the adjustment boards so that when they are finally announced they will not be of such a character that they will disturb the labor conditions under the jurisdiction of the other boards.

"'With that situation existing I want to make this suggestion to Dr. Garfield, that he immediately call a conference of the representatives of both sides in the anthracite mining industry with the representatives of the Fuel Administration; that with the facts already available and those that may be available before the conference takes place or is closed, the conference endeavor to arrive at a wage rate that will be just and fair, compared with that paid other industries, and will not result in workers drifting into your industry from other industries or out of your industries into other industries; and that when you have arrived at what seems to you to be a proper wage rate it be submitted to this general wage board for its consideration before being approved by Dr. Garfield so that it will know and you will know that your wage scale is not out of line with the general wage conditions of the country." In accord with this plan a meeting of the Conciliation Board with some union men was held Oct. 3, representatives of the Fuel Board being present.

Let Us Have "Business as Usual"

A BANNED expression is "Business as Usual," but it will serve well in the campaign against influenza. We must not let this disease interfere with our production and reduce the earning power of our men. Production is attained in part by hard work, but, at least equally, by hard-headed foresight. Many a man with eye too fast set on the main effort overlooks the possibility of attacks on his flank which will overthrow all his direct efforts.

Such flank attacks on production have already been made by ignorance of the important part coal plays in the war, by the failure of supplies, and by the delays in repairs; but influenza seems to menace a weak point at which we may, if we do not watch, suffer an even more considerable setback. Let us watch and ward against it and cause everybody to know the danger of this attack and so be ready to make the sacrifices which combating it successfully will inevitably require. Let us convince everyone that the victims of the disease cannot disregard it with impunity. Such disregard will jeopardize the lives of neighbors and fellow workers and will seriously threaten the life of the person who thus strives to regard the disease as unimportant and negligible.

The mine doctor must be energetically supported by the efforts and money of the operator. The coal industry has repeatedly urged that it could not protect its men and secure their welfare because there was no profit in mining coal and no funds were available for any but the most obvious and unquestionable essentials. If now that the industry is conducted at a profit we fail to spend the money necessary to keep disease away from our mine villages or to isolate what disease finds lodgment there, we shall not only fail to make the money which would otherwise come to our hand but also prove untrue our reiterated contention that a happy mining camp is one where the owner is making a provident return on his investment.

Now is the time for the operator to show his leadership and his great powers for good. There are leaders a-plenty in every mine village, but too often the man in control of the plant is not the leader of the men employed in it. He should recognize the opportunity which his position gives him and assume the leadership that should be his.

Congress has clearly visualized the importance of the menace from influenza. It has voted $1,000,000 to the United States Public Health Service that it may have funds adequate to combat the disease. Every mine owner, superintendent, mine foreman, engineer and mine worker should be studying this epidemic and learning all he can about it and how to prevent it from spreading. Those whose business it is to attend to the sanitation of villages should immediately obtain all the information they can from local or state health authorities or the United States Public Health Service.

It is a national duty to keep well, for to keep well is to maintain production and to sustain our national cheerfulness and poise. Only by health can we keep our home fires burning brightly. Health has more to do with morale than has almost anything else, therefore let us keep in health that our business of war waging may continue "as usual."

"We've Started Something"

THE townspeople were assembled at the city hall to say farewell to a draft levy. John and Susie, brother and sister, aged 8 and 6 respectively, had come hand in hand to see their uncle Joe march away. Susie's eye became fixed on the W. S. S. sign on the city hall lawn.

"John," she queried, "What do those letters W. S. S. mean on that sign over there?"

This was several months ago, and John had not the slightest idea of what the letters meant. It would never do, however, to be "stumped" by a girl, particularly by his younger sister.

"Why, Susie," he replied promptly, "I thought everybody knowed that! That's easy! W. S. S. means 'We've started something.'"

This country has indeed "started something"—Cantigny, Chateau Thierry and the St. Mihiel salient form a good beginning. The Hun is commencing now to realize the strength and mettle and purpose of the enemy he so vehemently scorned and derided a few short months ago.

It is, however, far too early yet to boast of victory or flatter ourselves over the successes already achieved. The German war machine is still unbroken; the will to dominate the world and the destinies of mankind is still virulent; hell-bred, beer-soaked *Kultur* is still rampant. Those who have lived and flourished by the sword have not yet perished by the sword. The fires of hate and greed still burn furiously. The principles in the defense of which this country entered the conflict have not yet been fully vindicated.

The United States is calling upon its people to lend of their substance in the nation's defence. To us here at home the war is something vague and remote. We have not ourselves seen with our own eyes the work of *Kultur*. Had we been able to do so the entire amount of the Fourth Liberty Loan, vast though the figure is, would have been oversubscribed within 24 hours.

If we citizens of America—proud to be men among men—saw our aged fathers and grayhaired mothers crucified upon the doors or fences of what had been their homes, or dragged away to industrial slavery in a foreign land; if we saw the hands of our sons severed from their wrists in order that they might never be able to defend themselves against a merciless and unprincipled oppressor; if we saw our innocent little ones carried about our streets impaled upon German bayonets;

if we saw our wives and daughters dragged off to a slavery worse than death, to at best be the playthings and toys of German officers, or carried into the front line trenches and there tortured by means and methods unspeakable in order that their shrieks of agony might lure the opponents of *Kultur* into effective range of machine-gun fire—if we could see these things would we hesitate to subscribe to the Fourth Liberty Loan?

All of this and infinitely more is a stern reality in Belgium and northern France—and only the accident of geographical location and our ability to oppose might with might protects our own land. Our two million men, more or less, now "over there" have given and are giving an excellent account of themselves. They will soon be followed by millions more. But all of this vast man power will be useless unless these boys are supplied with tanks, guns, shells, rifles, cartridges, automobiles, horses, airplanes, etc., without stint. Money quite as truly as men is what wins wars.

"We've started something," and we can and must and will see it finished. A certain family group of seven men in Germany must learn a definite lesson in English. That lesson is the meaning of the historic American phrase "unconditional surrender."

Buying bonds will help them learn it quicker.

Want Pay for What Others Endured

NOTHING has been done thus far to change the wage of mine workers in the anthracite region, but it seems almost inevitable that some change will take place. The large wages given to munitions workers and shipbuilders are causing the mining industry to lose its men and lose some of the loyalty of those who stay on the job. It must be remembered that the big wage paid to these munition and ships men is to compensate them for the discomfort, real and imaginary, and for the expense actually incident to changing one's occupation and place of living. The cost of living and residence also is high where these wages are paid.

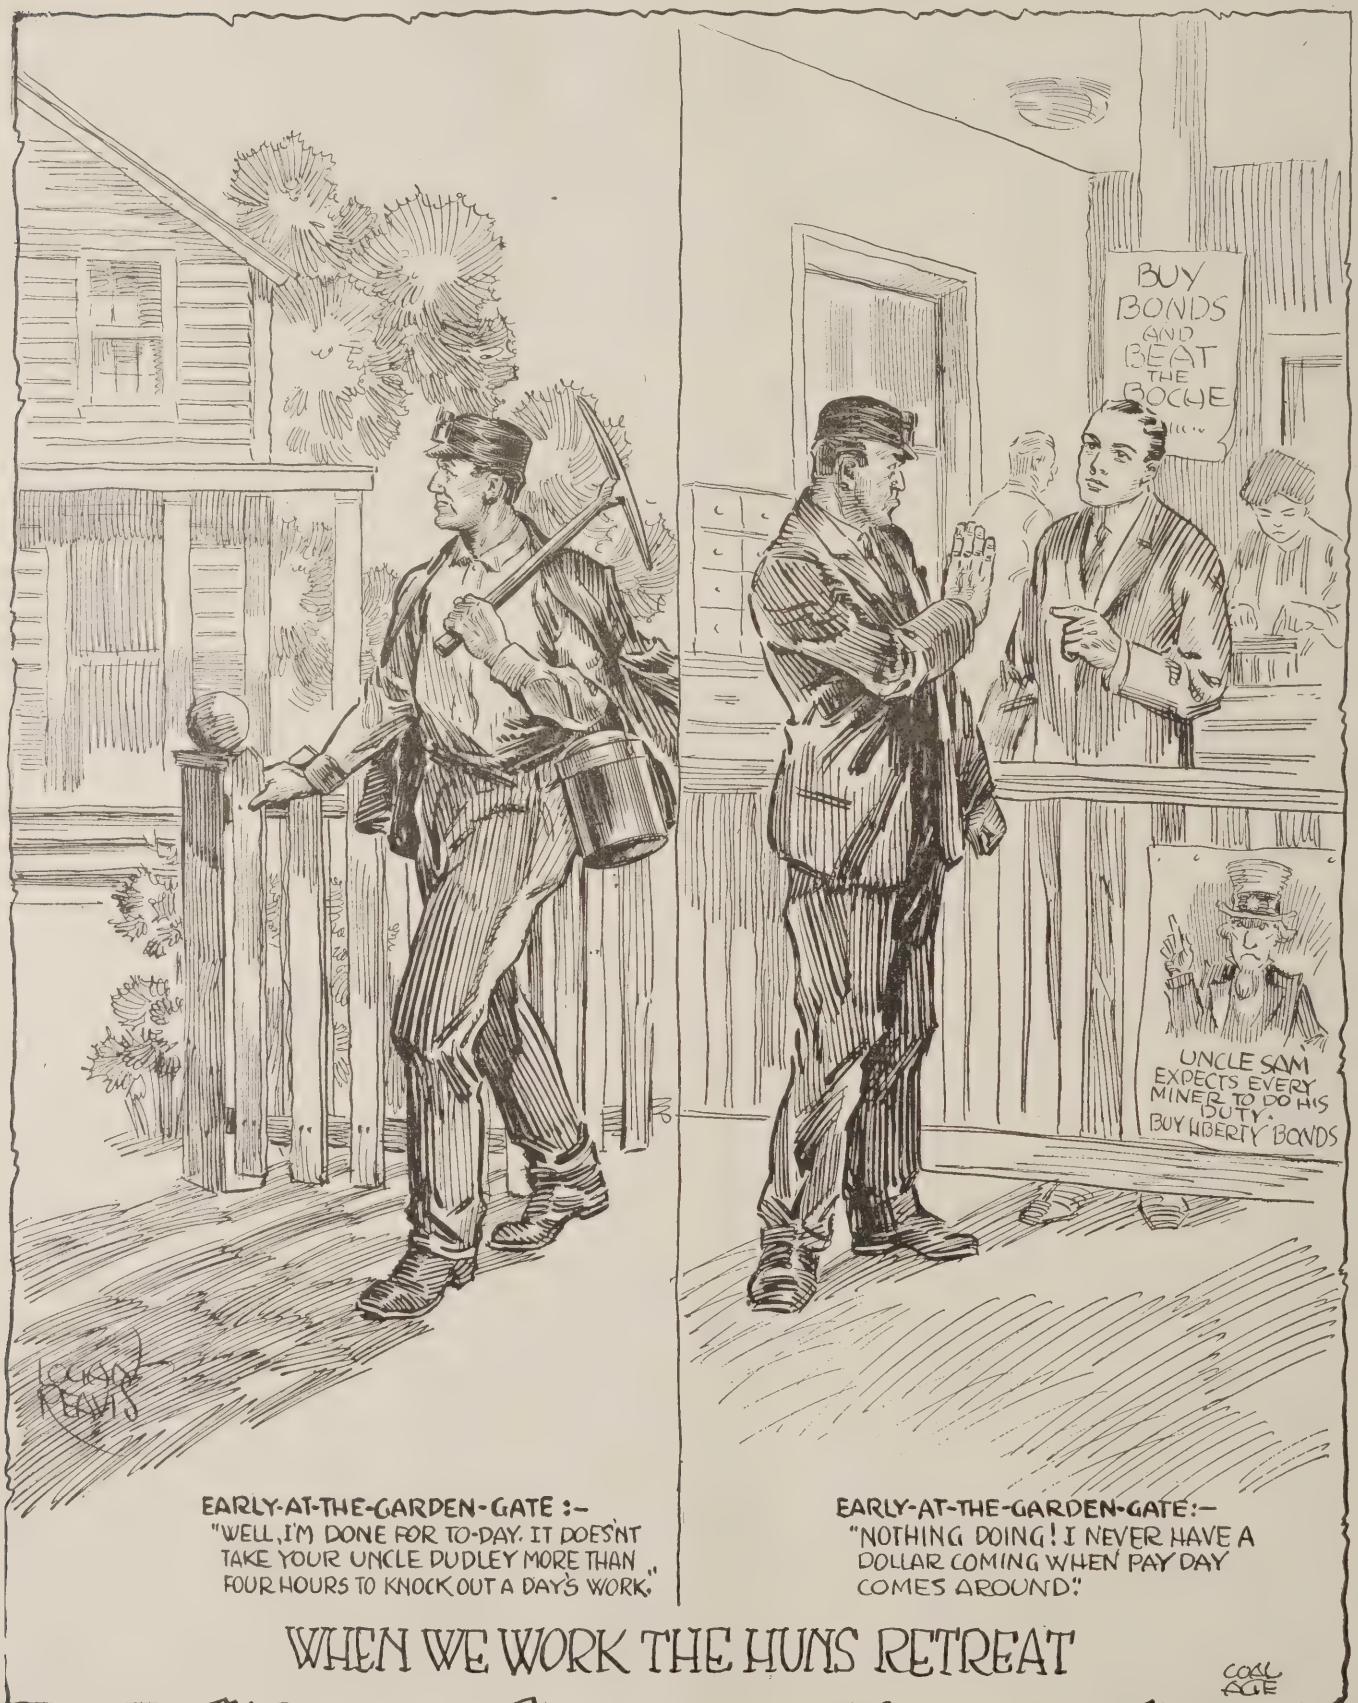
The miner who has stayed at home has saved much by remaining steadily at work, by not paying his good money away for moving expenses, by remaining as a skilled hand instead of entering another business at which he would be a common laborer, by paying reasonable rent, and in many other ways. To leave home or to move one's family is not worth while unless large earnings accrue. No one knows how long munitions will continue to be made, but just as soon as they are no longer needed the volunteers for work in munitions industries will be disbanded, and the savings, if any, will be frittered away in returning to the home town or in seeking for work where men have become far more plentiful than jobs.

The munitions wage is a dynamic wage; it is intended to move men. The mining wage is a static wage, intended to hold them. Unfortunately, the dynamic wages have had such kinetic energy that they have taken men from both essential and nonessential industries.

The increase in the bituminous coal regions made at the close of the year was granted in the main because work was so irregular that it was hard to keep starvation from the door. Now, that work is steady and it is hard to keep the men at work, the reason for much of that increase is not apparent. But as a permanent revision was made to accommodate a temporary condition, the bituminous miners are still receiving compensation for a hardship which they no longer endure. And now the anthracite miners, viewing the larger pay in bituminous mines, demand that they receive compensation for a hardship that they never endured recently or at any time within a decade and a half.

Thus the anthracite miners want pay for moving expenses though they have never moved, for the temporary character of their work though their work is permanent, for change in occupation though their occupation has not changed, and for slackness of work though they have had full-time operation. They desire pay for the sacrifices that others have made, to repay expenditures that they themselves have not disbursed. After all, what is more natural? How many of us are there who, when we passed the queue of men drawing their semi-monthly pay at a neighbor's mine, have not wished that we might range ourselves with the rest and get pay for services we never performed.

When John No Longer Defers to You



SOME have said that after the war the workman will come into his own. It is hard to say what is meant by this mysterious utterance, but shallow thinkers regard it as being of the highest importance. Certain it is that the working man always had a vote which was as potent as that of his employer. In any industry the workmen could always outvote the owners. No one has suggested yet that each employee should have two votes and the employer one. So, clearly, there is not going to be any great change in the political make-up of the United States.

But it is quite likely that the workingman will no longer defer to the judgment of his employer as freely as he has in the past. Already the worker has largely ousted the employer from the leadership which the employer formerly held without much question. The workman has leaders who come from outside and pay scanty deference to the men who own the plant and those who are paid to run it. These leaders, however wrong they may be (and they are not always wrong), however dishonorable they may be (and they are not always dishonorable), are always shrewd men. They have taken the leadership and in many cases have the worker's ears and his eyes.

The only way to meet the difficulty is the democratic way. The humblest worker in the mines, whether native or foreign, has a good keen intellect; and he will respond to the wiser head in the contest of wits. He is determined to know why he should vote a certain way and conduct himself in a certain manner. Let us have our reasons ready.

But let us studiously avoid a campaign of vituperation. The labor leaders are quite generally good clean fellows. A good clean warfare will tend to make them better and cleaner and straighten those who tend toward a less honorable course. For the operator to abuse and misrepresent them will be for him to accept those courses of action which he has most bitterly condemned. But if he places the truth fairly and squarely, before his men, and does it with good judgment, a degree of zeal and steady persistence, his work will tell and he will have nothing to fear.

"Early-at-the-Garden-Gate" Couldn't Buy His Share of Liberty Bonds

Who slacks at his work will be slack in buying Liberty Bonds

DISCUSSION BY READERS

The Miner and Safety

Letter No. 1—In anticipation of the recent meeting of the National Safety Council, at St. Louis, *Coal Age* invited its readers (Aug. 15, p. 324) to offer any suggestions or contributions relating to the safety of coal miners. It was urged that the readers of *Coal Age* "cover the whole field of mining safety and mining welfare." It was stated that one's duty to the industry and to the Nation should lead him to communicate to others whatever ideas he may have worked out in his brain, with a view to increasing the efficiency and safety of mining work.

In the issue of *Coal Age*, Sept. 12, which was devoted wholly to the safety and welfare of miners, L. R. Thomas, section foreman, Woodward mine, at Edwardsville, Penn., page 518, has drawn attention to the fact that it is the experienced miner who is the most frequent victim of serious accident, because of his foolhardy disregard of the precautions that he knows should be taken to insure safety.

Mr. Thomas has expressed my sentiments exactly. It is the practical miner, who knows it all and does not need the instructions of his boss, who disregards the simplest precautions for safety and, as a result, is injured or killed. The instance given by Mr. Thomas is a pointed illustration of that fact.

It is common to speak of the large number of foreigners who come to our mines seeking employment, as "greenhorns." But it is the "greenhorn" who listens to the instructions of his boss and obeys them. For this reason, he is safer, today, when working in the mine than many experienced miners, although there are many of the latter class among the foreigners, men who have been in this country a number of years.

In answer to the instructions of the foreman to do some posting or pull down a loose piece of slate or set sprags under his coal, the old miner answers, "Me verstay; me see; me know." The foreman passes on to the next place and this experienced miner continues his work, paying no heed to the instructions given him. It is not strange that his disregard of necessary precautions eventually costs him his life. But, that is the way of all miners, whatever their employment, from a greaser up. Their reply to the instructions of the foreman is always "Me verstay; me see; me know."

In the interest of safety, I have served as a moving-picture actor for the Coal Industries Films Co., which has caused me to take particular notice of some of the cartoons recently published in *Coal Age*. Kindly allow me to present the following sketches, illustrating the pleading necessity for a miner, regardless of his previous experience, to take the instructions of his boss kindly and obey them.

The first sketch shown illustrates a miner leaving his home in the morning and halting for a few moments to listen to the pleadings of his wife to be careful about his work in the mine that day. The wife reminds him that the little one she holds in her arms will be looking and calling for him at night. The father kisses the child and promises to obey all instructions. What is the result?

In the second sketch the same miner is observed standing a post under a loose piece of slate overhanging the face of the coal in his room. His laborer stands back and watches him. By thus posting his room he not only fulfills the "Safety First" promise given his wife in the

morning, but avoids the accident that befell his less careful neighbors who worked in the adjoining room.

These men, as indicated in the third sketch, took a chance, neglected to set the needed post and started to load their coal without examining and testing the roof above them. The result is that one was caught in the fall that took place a short time later. The unfortunate miner is shown in this sketch partly covered by the fallen slate.

In the fourth and last sketch is shown the return of these two miners to their homes, the one assisting to carry the stretcher on which his neighbor, the dead miner, is carried back to his sorrowing wife and children. The contrast is strong. These miners were neighbors, at home and in the mine. Both were experienced miners; but, while the one obeyed the instructions given him, the other relied on his experience as a miner. The sketches tell the whole story.

Permit me to suggest, in closing, that the cartoons relating to coal mining can be made more natural. They will then impress the miner more with the truth they are intended to convey. M. H. G.

Leckrone, Penn.

Value of the Mining Engineer

Letter No. 1—A short time ago there appeared in *Coal Age* (May 4, p. 823) an article bearing on the value of the services of a mining engineer, to the coal operator. If I remember rightly, that article was written by an inspector, who emphasized the absolute need of a comprehensive and accurate mine map based on surveys regularly made each year. Allow me to comment briefly on this matter, to show how some of the supposed difficulties in the employment of an engineer can be overcome.

Many small operators, in the past, have disputed the necessity of employing a mining engineer to enable them to operate their mines successfully. Their claim was, first, it would be expensive; second, the mines were too small to require the services of an engineer.

These fallacies are being gradually dispelled, and the technical man or engineer, today, is in demand, by all companies small and large. It is true, however, that a small operator is not able to employ an engineer constantly and several plans have been suggested to overcome that difficulty.

In some instances, the engineer's time is contracted for at stated intervals when he is required to make the necessary surveys and construct a map showing the various features of the mine, the property owned or leased and the surface improvements. While this plan has worked well in a few instances, it has been found inadequate at times.

Another plan, not so generally followed, is for the operators in a certain district to hire an engineer to serve them entirely, the engineer being required to devote prescribed portions of his time to each company. It is agreed, however, that all the companies have the privilege of consultation, at any time desired.

Advantages of a Coöperative Arrangement

While this latter arrangement has its advantages, some have criticised it by saying that the engineer would have his favorites and be partial to some of the companies, to the detriment of others. Such a claim would seem to be frivolous and hardly worthy of consideration, reflecting as it does on the integrity of the engineer. There are, no doubt, men who gain admission to all professions, which they serve to degrade by such dishonest, unprofessional and partial practice.

Speaking from my own experience, after working under both of these plans, the latter appeals to me as being far superior to the former. By its adoption, the operators in a district get together and employ an engineer who promises to give his entire time to their interests, while they agree among themselves as to what portion of the engineer's time each will require for the execution of their surveys and maps. The balance of the time the engineer spends in visiting the various properties, inspecting the workings and giving such advice and assistance as may be required to solve their local problems. In the performance of this work, the engineer keeps in touch with the conditions in each mine, and the problems, in each case, are constantly before him.

In contrast with this plan, that first mentioned has the disadvantage that one operator alone contracts with the engineer for a specified amount of his time, each year. It is true he gets the man's time; yet, does he gain in the end, over the other plan in which he can consult with his man at any time, while securing a due proportion of his services, according to agreement? In the first instance, the engineer probably has outside interests that are more profitable to him and demand the most of his thought and energy; but he accepts the operator's contract to keep him employed.

One great disadvantage in the plan first mentioned is the fact that the engineer sees the mine but once in a great while. In the interim, he is apt to have forgotten many details and the peculiar conditions affecting the work. For those who cannot afford to employ an engineer on their regular staff, the first mentioned plan is certainly better than none; but in a district where such an arrangement is possible, the second plan will be far more satisfactory and give better results in the end. Golden, Colo.

Americanizing the Foreigner

Letter No. 5—Fresh from the big cities teeming with life and energy, grimy with coal soot but vibrating with the giant heart-beats of a great nation, I came three months ago into this peaceful valley among the great hills. What a contrast from the region I had left behind, far from the coal fields! But I came here with the thought that I might work to better advantage in helping to win the war.

Until last winter, when all the great manufactories of the country were shut down for lack of fuel, the coal industry had been a closed book to me. Since coming into the coal fields, however, my associations have brought me into closest contact with this great arm of American industry. It occurs to me that, as a stranger, unhampered by prejudice or habits, it may be that my observations may help those who are studying the labor situation in its relation to the output of coal.

Mention has already been made in *Coal Age* that, in mining camps where men own their own homes, conditions are much more satisfactory than when they are compelled to live in company houses. This appeals to me as one of the chief factors in coal production. Its truth was impressed forcibly on my mind, a short time since, when a committee of women were around soliciting Red-Cross funds. It was between paydays and, although these negroes and foreigners, many of them, had earned as high as $200 for a two weeks' pay, they had no money to give.

Although well housed, on premises that were neat and orderly, the general attitude of these peoples was both listless and shiftless. Looking at them, I could not but feel that had they had the privilege of buying little houses and lots that they could call their own, it would be a great incentive to them to work and stay in one place; there would not then be the desire to depart and seek work elsewhere.

On the other hand, in a mining camp where the coal company own the entire colony, there is no hope of the men accumulating anything. The man who came from Europe, seeking freedom, political and otherwise, braves poverty and the perils of the unknown, for the sake of his principles. Such a one soon feels the yoke of the restrictions of this mining camp and drifts away to the big cities where he seeks employment affording greater opportunities.

Only a few days ago a miner came into our commissary, and, while serving his wants, I engaged him in conversation. He was a clean-cut Hungarian. He told me he was leaving the next day for Chicago, where he could attend night school and study English, which would greatly improve his chances. He told me that the average foreigner, notwithstanding the general belief to the contrary, was a downright intelligent person. He argued that, lacking intelligence, these men would not have the courage to throw off the yoke of Europe and come to a strange country. He added that when foreigners come over here and contempt is shown them as a class, not to say individually, it arouses resentment, which is natural.

While frankly admitting that there were exceptions to the rule, my man was strong in the belief that the more intelligent of the foreign element were essential to every industry, particularly mining. When he left I reflected on the truth of his last statement. Industry everywhere needs brains; but strong backs and weak minds are not essential to any operation. My conclusion was that the more intelligent a worker is the more eager he is for advancement. The thrifty miner is not content to live in any other than his own home, be that ever so humble.

The Labor Problem of Today

The most difficult feature of the labor problem, and the hardest to solve, is the relation of the American element to the foreign element. Although living within a stone's throw of each other and in daily contact, they are quite separate. They meet in the mine or in the commissary but the foreigner is generally morose and unfriendly. Practically the only time when they display enthusiasm is on one of their holidays.

Seldom does one observe any attempt on the part of the American population to mingle or become friendly with the foreign element. Replies to my inquiry state that this has been attempted but without success. However, my own experience when approaching a foreigner with careful tact is that he is easily won. My conclusion is that, in the large majority of cases, they are not approached in the proper way but have been handled as a class. Their educational advantages have been very limited, and when the supply of labor is equal to the demand the foreigner is often neglected.

Let me urge that it is the American element, as much as the foreign element, in our mining camps, who need waking up to the necessity of putting their shoulders to the wheel, in a way that is necessary to the success of any industry, war or no war. Honest efforts must be made to teach these new citizens how to become good Americans. Much has been done along this line in the public schools; but how much could those efforts be furthered if American mothers and school children would welcome into their mothers' clubs the foreign mothers in their midst. Patience and good-will are required to make them understand our purpose, which is to bring them to appreciate American ideals and standards. After all, it is the home that breeds either satisfaction or discontent.

Social service work in these homes, I know, has been attempted in the past with varying success, but it must be continued with patience and perseverance. Although foreigners are loath to mingle with Americans in a social way, they will attend public gatherings; and if a few earnest women would get together and form mothers' clubs I feel sure much good would be accomplished. The entertainment at the schoolhouse is always successful in drawing different classes of people together, and filling the house with a social throng.

When the foreign miners see that a real spirit of coöperation exists, they will be drawn to love this country of their choice. and they and their children will be Americanized and the foundation of great things will be built. At the same time, the miner will better understand his work in the mine. As long as there are a few intelligent foreigners in any group, and there always is, these are a source of encouragement to the worker.

Let coal companies do more welfare work, establishing and maintaining night schools for the teaching of English. This is constructive work and will accomplish its purpose. It will prove a real benefit to the company, but that is incidental. The true purpose is patriotism and love of country.

J. Tague.

Holden, W. Va.

Exemption for Coal Miners

Letter No. 1—Owing to the shortage of labor, in coal mining, the suggestion has frequently been made that this class of labor should be exempt from the operation of the draft law. It is gratifying to know that a number of *Coal Age* readers who are contributing to these columns express themselves as opposed to such a plan. I was particularly pleased to read the letter of Ostel Bullock, *Coal Age*, Sept. 5, p. 462, in which he gives good reasons why there should be no class exemption for coal miners.

There is no question but that the draft law has already called many good miners from their work in the mines and sent them to the front to take part in the great struggle for democracy. The point I would emphasize here is that a ruling granting exemption to coal miners, at the present time, would be apt to cause hard feeling among the relatives and friends of those miners who have already been called to service, many of whom, we regret to say, will never return.

Now, regarding the situation from a patriotic angle, we must agree that there is no patriotism in urging a claim for the exemption of miners as a class. While it is true the mining ranks have been depleted by reason of the draft, it is likewise true that all other means to produce the required tonnage of coal should be exhausted before attempting to discriminate in favor of the mining classes. As Americans, we stand as a unit as soldiers and workers in every craft producing the necessities of war.

Observation makes clear that there are many able-bodied men working in nonessential trades and indus-

tries. These should be forced into other occupations that are necessary for the prosecution of the war. It is true that they would make poor miners at first, being inexperienced in that line. Like the soldier, they would have to be trained, but this would not be as difficult a task as may be supposed. Many men having no more experience than these have gone into the mine and succeeded.

In my opinion, it will be necessary after the war to train new men for mining work, and we might as well begin to do that now. Let me urge, then, that we do not favor the exemption of coal miners because they are miners, but let us all stand shoulder to shoulder and be loyal to the call of our country.

Perryopolis, Penn. R. W. LIGHTBURN.

Hindrances to Coal Production

Letter No. 3—Among the many hindrances to the production of coal that have been suggested in the letters written on this subject, perhaps few are of greater influence than favoritism in the management of a mine. Instances in my own observation impressed me with the thought that this is a great factor in the discouragement of ambitious mine workers, whose zeal in the work is greatly lessened thereby.

As years come and years go, the men of the mine have their memories that rush over them, perhaps, even to a greater extent than is true of workers in other industries. In some ways it is amusing, but, in others very discouraging, especially for the young man who has progressive ideas and hopes for his own future advancement.

Here, for example, is a young man progressive, thoughtful and ambitious. An idea comes to him that he submits to his foreman as a suggestion for bettering the conditions in his particular branch of the work. The suggestion may not appeal to the foreman, who, in a condescending way, replies, "I will see to it," and that is the last the young man hears on the subject.

Is it not surprising there is no incentive to sincere coöperation when an honest effort of a thoughtful man meets with such a reception on the part of his boss? Today we are all striving to reach the goal of success, and it requires concentration of thought and the coöperation of all workers.

A Foreman's Favorites Sure To Follow Him

Only recently, an instance occurred that showed clearly the ill-results of favoritism on the part of a foreman who was transferred from one shaft to another, in the working out of the plans of the company. The foreman previously in charge, in that mine, was a man of few words but full of pep. He was accustomed to allow his assistants many privileges, while he watched their every move and gave an attentive ear to any suggestion that meant another car of coal on the shaft bottom. Following a good day's run, he would meet his men at the bottom of the shaft, complimenting those whose efforts deserved recognition and cautioning others who needed to speed up. There were delays that were unavoidable in this, as in other mines, but these he passed slightly over.

It was not many days after the change of foreman that new faces began to appear on the shaft bottom. They were men whom the new foreman had been accustomed to treat with special favor in the other mine. A little later, almost everyone who was a favorite in the other mine had found a place here and was working under his old foreman from whom he received the same privileges as before. The result can easily be imagined as to the effect on the mine workers of longer standing, some of whom were displaced to make room for the newcomers and all of whom missed the friendly and helpful words of their old foreman.

There are foremen who are desirous of showing their authority on all occasions, but the time is fast passing when such men can successfully manage a mine. Such a foreman must now step down from his high perch and listen when a complaint is made that he can adjust with satisfaction to all and without discharging a man who is probably the innocent victim of prejudice or the jealousy of a fellow worker. The following incident will show how the failure to make such an adjustment cost one foreman the loss of a good worker:

Having recently studied on a plan to increase the output in my district, I put it up to the men with the result that one man and his laborer turned out 144 cars of coal in a month, and several others did nearly as well. It happened, however, that the man just mentioned had a little trouble that hardly amounted to anything. The foreman listened to his complaint but refused to adjust the matter, turning the man down flat. Knowing that he could secure work anywhere, the man loaded his tools and quit.

Practical Results of "Playing Favorites"

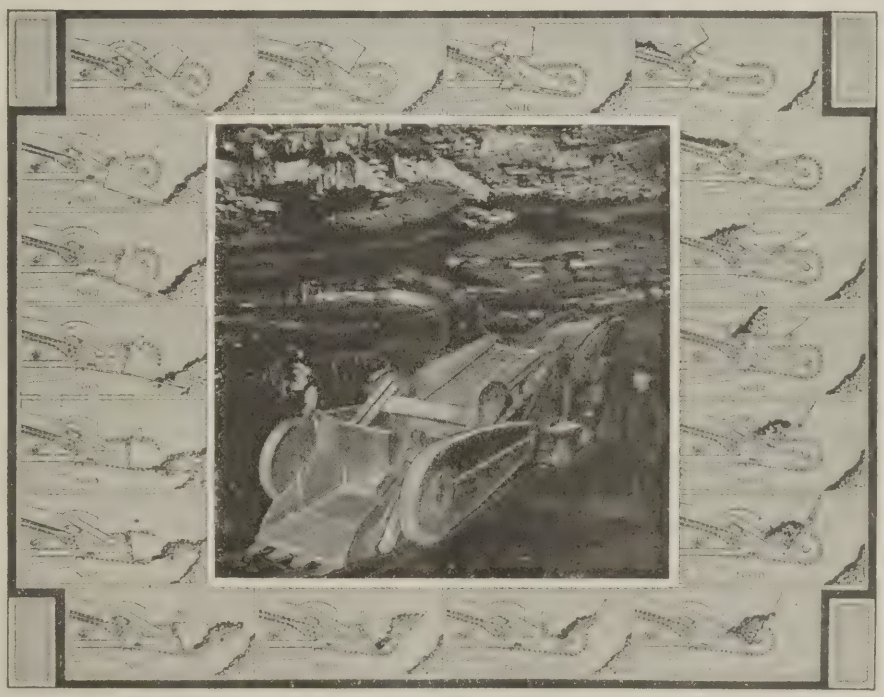
Now, compare the result. The foreman at once gave the place to a favorite, who, in 27 days, loaded only 90 cars of coal, a decrease of 37½ per cent. in the output of that one place. This instance is only one of many that are occurring daily in our mines and which are the direct results of favoritism on the part of many mine foremen.

A few days later, the miner who had quit his place came around for his pay. The superintendent met him and asked him to come back, telling him everything would be all right. On the strength of this, the next morning found him at the mine ready to go to work. The foreman, knowing that he could not set aside the authority of the superintendent, took the man into the mine and showed him one of the worst working places there. He knew well that the miner would quit before he would work the place, which would give him, the foreman, an opportunity to override the authority of the superintendent.

It can readily be imagined that the superintendent knew that the foreman was playing favorites. It was a matter, however, that he did not feel warranted in going further to adjust, which would mean taking the matter up with the management and result in a possible cause of friction between himself and the foreman, whose right to authority in the mine is generally recognized.

Let me urge, then, that it is time for mine foremen to set aside the old method of handling men and cease to play favorites. Let us be progressive and coöperate with our men, who will give better work in the knowledge that they can get a square deal in return.

Plymouth, Penn. JOSEPH R. THOMAS.



INQUIRIES OF GENERAL INTEREST

Face Coal Shoveler and Loader

Kindly permit me to refer to the inquiry relating to "Improved Coal Equipment," *Coal Age*, Sept. 5, p. 465. In answer to the question asking for the most up-to-date coal-loading machine, the Jeffrey machine is mentioned as being the only one designed for loading coal at the face. While it is true that the Jeffrey loader is a light and portable machine that has given good satisfaction where it has been installed, allow me to ask if mention should not have been made of other devices and machines used for this purpose. INQUIRER.

———, Penn.

Passing over, for the moment, the numerous types of conveyors and scrapers employed for this purpose, it is true that the shoveler and loader designed and manufactured by the Myers-Whaley Co. should receive attention. This machine has been largely known as a "shoveling machine" and has been used in quarries and underground work where loose material of any kind needs to be shoveled up and loaded into cars. The Myers-Whaley machine differs from other loaders in the fact that no hand shoveling is required. In the case of conveyors and other types of loaders, the material must be shoveled into the machine to enable it to be loaded into the cars, while this loader is equipped with an automatic mechanical shovel, so constructed that it is able to scoop up material of any size that will enter the shovel and load it into the car.

The machine operates equally well on rough or smooth pavement, and there is less breakage resulting in the shoveling of coal than when the work is performed by hand. Not only can the machine be used to shovel material from the floor but it will spade into a heap of material, at any point above the floor. Also, the material can be discharged immediately behind the machine, in line with the shoveling, or on either side of the track, as desired. Incidentally, it may be mentioned that the conveyor that elevates the material and transports it to the car serves also as a picking table, for the separation of any slate or rock that might be mixed with the coal. The accompanying figure shows the Myers-Whaley shoveler and loader at the face where the coal has been shot down and is being loaded into a mine car.

In view of the severe conditions under which this shoveler and loader must operate, great care has been taken in its design and construction. The best obtainable material is employed and every movement and detail simplified. The machine is built for strength, durability, economy, and efficiency. All castings are of steel and forgings have been used wherever possible. The conveyor is so designed that the surface subject to abrasion, by the material, is made of steel bars, leakage being prevented by the belt to which the bars are bolted. Lubrication of all principal parts is effected through pressed-steel compression grease cups mounted on the bearings, in most of which brass and white-metal renewable linings are provided. This shoveler and loader is operated by one man. The power employed is either electricity or compressed air, depending on the conditions of equipment at the particular mine where the loader is to be installed. Like other loaders of this type, the machine runs on a track but may be equipped with traction wheels. It is self-propelling, forward or backward. A feature that should be mentioned in connection with mine work is the fact that there is no difficulty in operating the machine on straight or curved tracks.

In its construction, the machine is built in three sections, the main frame is mounted on a truck and carries the motors for its operation. Attached to the forward end is a swinging jib equipped with a specially designed shovel, which scoops up the material and, turning over, deposits it on a conveyor that acts as an apron over which the material is carried to the rear conveyor that transports and deposits it in the car.

The power consumption of the No. 4 size machine is 0.22 kw.-hr., per ton of material loaded. In continuous loading, this machine can handle from 200 to 400 tons in an 8-hour shift and can work in a 6-ft. headroom.

EXAMINATION QUESTIONS

West Virginia Examination (1918), Mine Foremen and Firebosses

(Selected Questions)

Ques.—State the law in regard to safe travelingways. Why are manholes necessary? In your opinion, why are so many men injured by falls of roof—by mine cars? What should be done to eliminate this?

Ans.—The mining law of West Virginia (Sec. 21) requires that a travelingway not less than 5 ft. high and 3 ft. wide, be maintained at the bottom of a hoisting shaft, to enable men to pass around the shaft, without going under the cage.

Sec. 31 of the law specifies that a safe and available roadway, properly drained, shall be available for the passage of men, at all times when the mine is in operation, to enable them to reach one or the other of the two outlets to the surface.

Manholes should be provided on all haulage roads where men are obliged to travel, and at the foot of all slopes or inclines to enable men to seek refuge from moving cars or trips. Injury from falls of roof are largely due to the neglect of mine workers to make their places safe by timbering, or to the insufficient timbering of roadways and travelingways. Also, to the neglect of miners to properly inspect and timber their working places before starting to load their coal into the cars.

Injuries from the movement of cars are due largely to the failure of the management to provide separate travelingways for the men to reach their working places, and requiring them to travel haulage roads where there is insufficient clearance room at the side of the track, and refuge holes are not available. Accidents of this nature are also due to the failure of drivers to sprag their cars when descending grades, or to the location of a door at the foot of a grade, or to the disobedience of mine regulations and rules by men who persist in riding loaded cars and trips passing out of the mine.

In order to reduce to a minimum the number of accidents occurring in the mine, a closer inspection of all mine roadways, travelingways and working places is necessary, and the enforcement of strict rules and regulations relating to safety; also, the maintaining of an ample supply of timber required in the mine and providing every appliance that will make the mine safer for work.

Ques.—If you were traveling in an air current of high velocity, with a safety lamp, and you suddenly came in contact with an explosive firedamp mixture that filled the lamp with flame, and you had no means of smothering it, explain how you would protect yourself from danger.

Ans.—This question assumes a condition that a careful and competent fireboss would rarely meet. It is difficult to understand how a man, traveling in an airway where the current has a high velocity, would suddenly meet with an explosive mixture that would fill his lamp with flame, except the gas was coming from a strong feeder in the entry or was issuing from a room. It must be assumed that the man in question is traveling with the air, as otherwise the gas would be diffused in the air current, and its presence would have been detected by any good fireboss on his first entering the airway.

However, if the gas encountered was coming from a strong feeder or issuing from a room, a cautious fireboss, approaching such feeder or room and observing that he had entered a strong body of gas, would at once lower his lamp and retreat against the air, taking the precaution to shield his lamp from the force of the current. To do this he might be obliged to walk backwards holding his light in front of him to protect it as much as possible from the moving air.

Ques.—In your judgment, how often should the abandoned parts of a mine be examined?

Ans.—The frequency with which the abandoned parts of a mine should be examined will depend on their extent and character, as well as upon the amount of gas generated in them. Where there is a considerable abandoned area that is subject to constant roof falls, and the place is generating gas, daily examination should be made to ascertain its condition. Such places should be thoroughly ventilated to prevent the accumulation of large bodies of gas, which would be driven out onto the entries by a sudden fall of roof. On the other hand, a limited abandoned area that is in fairly good condition and not endangered by accumulating gas would only require an occasional examination, say once a week or as often as may be necessary to keep track of its condition.

Ques.—In making the examination of abandoned places, should you find an accumulation of explosive gas therein, what method would you adopt to remove the same or make those portions of the mine safe?

Ans.—Before attempting to remove the gas, care should be taken to ascertain that there are no men working on the return of the current. If possible, the work of removing the gas should be done after the men have left the mine. No open lights must be permitted in that section of the mine. The quantity of air passing should then be increased as much as possible. Following the air current, the men employed in performing the work should proceed with caution, making frequent tests of the air as they advance. Brattices should be erected to direct the air so as to sweep away the gas. It would be well to use as few safeties as possible, depending on electric mine lamps for light. The safety lamps should be well guarded against a rush of air caused by a possible fall of roof. The fireboss should employ only experienced men to assist him in performing the work.

COAL AND COKE NEWS

Harrisburg, Penn.

It is doubtful whether the present Liberty Bond campaign will reveal anything more remarkable than the fact that in less than the first two days of the campaign every one of the more than 16,000 employees of the Lehigh Valley Coal Co. pledged a subscription. What makes the record all the more extraordinary is the fact that this great force of employees made a 100 per cent. subscription in the preceding campaign. In singling out this company's working payroll for special commendation, there is no intention to undervalue the achievements reported by other coal corporations. Special reference is made to the Lehigh Valley because of the great number of its employees and because of their diverse nationalities, many of them being subjects of a country with which we are at war.

Charles M. Means, manager of the inspection section of the Federal Fuel Administration, states that he will put a special field inspector in the western part of the State at an early date with the object of cleaning out producers who are loading "dirty" coal.

Following a luncheon of about 30 coal jobbers of the Pittsburgh district on Oct. 1, what is known as the Pittsburgh District Coal Jobbers' Association, a branch of the National Coal Jobbers' Association, was formed and a constitution and bylaws to govern the organization were adopted. Temporary officers elected to conduct the meeting were Charles S. Bygate, president and William Carothers, secretary. The objects of the organization are to benefit and protect its members in handling coal in the Pittsburgh district as jobbers, distributors and purchasing or selling agents, to facilitate coal sales and deliveries and to improve methods of conducting trade and commerce in coal, and to encourage increased production.

Uniontown, Penn.

Fuel production records for the Connellsville regions were again advanced for the week ended Sept. 28 when the output totaled 744,842 tons. That figure is 16,528 tons above the output of the previous week and is 8221 tons in excess of the region's previous high record of Sept. 14. Had not electric power given interrupted service, there would have been no loss in coke of 4137 tons, which would have sent the weekly output past 750,000 tons. Coke shipments were 333,137 tons.

While the Baltimore & Ohio R. R. still has its car shortage in rather pronounced form, the shortage during the week was reduced to 30 per cent. The Pennsylvania system, however, is maintaining its good record, reporting placements for 100 per cent., both coal and coke. Barring unforeseen developments, that record is likely to be maintained indefinitely; at least so long as good weather prevails.

All efforts next week will be centered on the region's fall fuel drive. Eight hundred thousand tons is the total, which is 75,000 tons higher than the average for the region. The plan of the production committee is to strike a pace at 800,000 tons and maintain it until next spring. Quotas will be issued to every mine, and plant representatives of the production department will apportion an equal part of the increased output to invididual miners.

Fuel Administration officials in conjunction with transportation officials are bending every energy to provide favorable conditions next week, so that the loyal workers may be unimpeded by outside influences in their patriotic efforts to put the coke regions over the top. There is no doubt in the minds of fuel officials that the record will be reached by diligent application of the workers if those conditions can be controlled.

Charleston, W. Va.

A large loss of tonnage in the Fairmont region during the month of September has been due to execrable car service. The supply for the last week of the month was no exception. It grew worse as the week drew to an end. On Friday there were only 1418 cars in the district, and of that number only 597 had been placed in time to begin loading. The day before that there were 1500 cars, but only about 1000 were placed in time to begin loading. Friday seemed to be an extremely unlucky day for the region since a shortage of electrical power made it impossible for some of the mines to operate, and in some instances mines were forced to shut down.

The Pocahontas and Tug River districts, because of speeding up and a better car supply, produced 5797 tons more the last week in September than were produced the week preceding. In all 7337 hours were put in, the result being a total net tonnage production of 438,810. The chief cause for gratification was in the reduction of the tonnage lost through labor shortage. Tonnage lost from car shortage is now almost negligible, being only 944 tons, but mine disability caused a loss of 17,893 tons. The amount of coke manufactured was not so large as the last report showed, being only 46,946, or about 3000 tons under the previous week. Two million tons production is the goal for the Pocahontas and Tug River districts during October.

Miners in the New River district wound up the last week in September by a gain of 5568 gross tons over the previous week, the total production for the week being 154,668 gross tons. Car service in this district was about 100 per cent.

The Winding Gulf district produced 119,107 gross tons during the last week in September. The operators and miners are aroused to what is needed and with Foch's drive and the Liberty Loan drive gaining momentum, the entire personnel of the industry are determined to do their part. Measured in net tons the gain of the New River and Winding Gulf districts amounts to 23,404 net tons. In the Winding Gulf as in the New River district there is the fullest co-operation between the industry and all railroad operatives. In this particular district the car service is all that could be desired.

The Kanawha district continues its steady gain. Last week in September the total production was 217,809 tons, which represents a gain of 20,000 tons over the preceding week. The car supply was all that could be desired, the number of hours lost because of insufficient cars being 322. The total time required to get out the above tonnage was 6042 hours. The loss in time due to labor defection was only 579 hours.

Birmingham, Ala.

Greatly increased production of coal in the Birmingham district is looked for in October, with estimates of the output during the month of between 400,000 and 524,000 tons weekly, based on the efforts being made by every interest involved in the industry to bring about the largest possible output.

M. J. Sanders, director of Mississippi and Warrior River transportation, has promised that the Warrior River barge line will be in operation before Oct. 15, thus affording facilities for the moving of 20,000 tons of coal, which will be floated down the river to Mobile and New Orleans every 30 days. Within two months the system will have been so enlarged that twice that amount of coal can be transported monthly, relieving the car shortage and enabling the roads to handle an additional amount of coal to points inland.

The two seaports which are the chief consumers of bunker coal from this district, Mobile and New Orleans, report that although a great amount of bunker coal has been carried to those places by the railroads, there is still room for a further supply, and indications are that shipping interests will require a great additional supply to fill their demands during the next three months, the rush season.

There is need for coal at coke ovens in the district also. Some complaint has been heard of the quality of coke lately, as well as the quantity produced. Delay in finishing one of the largest coal washers in the district hinders production to an appreciable extent, but no remedy is available, both material and labor being scarce.

Several wagon mines in the Cahaba Valley are beginning to bring in coal in quantity, two trips a day being made by some of the wagons. Two to four and five tons of coal a day are being handled by each wagon.

Victoria, B. C.

Nichol Thompson, Fuel Controller for British Columbia, and the coal mine operators of this Province have received notice from Ottawa, Ont., that regulations providing for the more uniform distribution of coal needed for industrial uses in Canada have just been approved by the Governor-in-Council at the instance of the Canadian Fuel Controller.

They provide that all mine operators in Canada and importers of industrial coal in this country shall rotate delivery of coal among their customers in proportion to their requirement, so that no one shall at any time have advance supplies on hand while others are under-supplied.

A preference list of coal consumers is also outlined in the regulations. Those preferred consumers include railways, military and government buildings, public utilities, retail dealers and manufacturing plants chiefly engaged on war contracts. These must be given preference in supply over all other users in the order named.

Drastic provision also is made against the unnecessary hoarding of coal on the part of industrial users and heavy penalties are provided. Those whose operations required large advance stocks at the end of the present coal year must obtain special permission from the fuel administrator. Provision is made whereby mine operators and importers may require certified statements from their customers as to the tonnage of coal on hand and required for each month, so that an equal distribution may be made of all coal mined and received in Canada.

PENNSYLVANIA

Bituminous

Washington—J. W. Emery has sold to the Mingon Coal Co. the coal underlying a tract of land containing 181.876 acres belonging to Mary A. Leyda, Helen K. Leyda and Ross A. Leyda.

Pittsburgh—The Pennsylvania Bituminous Mine Inspectors Advisory Association, whose membership comprises the 30 mine inspectors, held a meeting at the Seventh Avenue Hotel, Oct. 4. The purpose of the meeting was to discuss mining matters and how they could best aid the United States Fuel Administration in keeping the coal clean and to help increase the production.

Connellsville—Edward A. McCoy, of Broad Ford, has purchased a farm of 106 acres in Lower Tyrone township with a portion of the coal underlying it, from J. Fred Kurtz and W. D. McGinnis, and has started mining operations there. The farm originally belonged to William Hay and S. Wowatski, who sold it to Messrs. Kurtz and McGinnis. The transaction with Mr. McCoy involved the sum of $8000.

New Castle—More than 1800 acres of coal and limestone land in Big Beaver township, valued at approximately $175,000, is included in a purchase made by the Crescent Portland Cement Co. of Wampum. The properties include the holdings of the Beaver Coal and Coke Co., Wampum Coal Co., Mehard-Dinsmore interests and Matthew Gunton. The new owners plan to increase the production and employ many additional men. Much of the coal mined will be used by the cement company for the operation of its plant.

Indian Head—The Melcroft Coal Co. which is opening an extensive coal field in the Indian Creek Valley, has completed 100 miners' houses and announced that it will construct 300 more in the spring. The electrical plant was started last week and the coal production has materially increased. The houses are unique in that the new mining town will not have two houses alike in design and will be painted differently in so far as the color scheme will permit. The houses are all equipped with modern conveniences and running water and light.

Indiana—The coal production of Indiana County has been greatly decreased by the epidemic of Spanish influenza which is raging in several of the mining towns near here. The Coal Run mines, where there are 450 cases of the disease and seven deaths, have been shut down entirely. Several of the officials are confined to their beds. The mines at McIntyre, Luciusboro, Fulton Run and Ernest are greatly crippled on account of so many of their men being stricken. The schools and moving picture theaters have been closed and nurses and doctors have been rushed by the state and federal governments to this county. Guards have been placed at all the towns and are enforcing strict rules as to arrival and departure of all persons.

Anthracite

Pittston—Mine workers in this vicinity are taking a prominent part in helping this district meet its quota in the Fourth Liberty Loan drive. At the Pennsylvania Coal Co. and the Hillside Coal and Iron Co. the workers have made 100 per cent. subscriptions, and similar reports are expected from employees of other mines now being canvassed.

Jeddo—Miners dropped their picks on Sept. 28 and put on exhibition some extremely large cabbage, potatoes and other vegetables at their annual war garden show. The G. B. Markle Coal Co. has given land to its employees free and has plowed it every spring. Between 15,000 and 20,000 bushels of potatoes were grown and 6000 heads of cabbage, as well as hundreds of bushels of other food products. Prizes were awarded to many of the successful amateur farmers.

Punxsutawney — Spanish influenza is wreaking havoc upon the mining town of Wishaw, six miles east of here. Nine-tenths of the population of 500 miners and their families are afflicted, 450 cases of the disease having been reported up to noon Sept. 30, and within the last few days many deaths have been reported. The only two physicians combating the disease have been stricken with the malady and have been forced to quit their work. The State Health Department has supplied physicians who have placed the town under quarantine.

Wilkes-Barre — Vice President F. M. Chase, of the Lehigh Valley Coal Co., in meeting new labor conditions by the employment of 50 young women in the office building to replace the young men who have been drafted, is now taking steps to make these young women comfortable. A rest room for the female employees is being fitted up in the office building and a professional nurse has been employed as matron and advisor for the girls. This is in line with the policy of this company in looking to the comfort and contentment of its employees, the Lehigh Valley being a pioneer in the movement for attractive colliery surroundings and better working conditions.

Shenandoah—Officials of the Philadelphia & Reading Coal and Iron Co. strongly deny that the company insisted on employees making a declaration to remain in the employ of the company at least seven years in order to secure exemption. It was pointed out that the company, in view of the fact that collieries have been crippled and production lessened by the large number of mine workers entering the service, is making every effort to secure the men necessary to keep the collieries operating at top speed, but no limit is placed on the time men shall remain in the employ of the company. Officials claim, however, that they expect men exempted because of their essential occupation to remain at work at the collieries at least for the duration of the war.

WEST VIRGINIA

Hartland—Work was started this week on the construction of a plant for the development of a tract of coal at Hartland leased by E. Fellabaum, of Charleston. Within a short time the lessor expects to have his plant in operation.

Huntington—Following a recent hurry call for coal consigned to Cincinnati, Ohio, to be sold by the Cincinnati Red Cross, 35 officials of the Lundale Coal Co., from the vice-president, general superintendent and secretary down, loaded four railroad cars with fuel before noon.

Peytonia—The Peytonia Coal Co. is about ready to begin operations at its No. 2 mine at this place in the No. 2 gas seam. By Nov. 1 the company expects to have the plant completed and to begin the shipment of coal. The mine will have an actual capacity of 200 tons per day.

Clay—With power to be supplied from a central station at Hartland, the Lima Coal Co., of Lima, Ohio, is arranging to proceed with the construction of its plant near Clay, including the erection of a tipple, many new houses, etc. Construction work will be begun at an early date. E. H. McCool will be in charge of operations.

Charleston—J. B. Hart, of the Hartland Colliery Co., has acquired a tract of 5400 acres of coal land in Kanawha County, the land being underlaid with Cedar Grove, No. 2 gas and other Kanawha seams, the newly acquired tracts adjoining the holdings of the Hartland company. Arrangements will be made to develop the property at an early date.

Fairmont—Among other improvements being made by the Chesapeake Coal Co., at its plant near here, is the installation of an electric hoist. Operations at this plant are in charge of J. J. Halcomb, superintendent.

Numerous improvements are being made at the plant of the Marion Gas Coal Co., near this city, a new water system having been installed. The company has also built a large number of new houses. J. D. Vutor is the superintendent at this plant.

ALABAMA

Bessemer—George H. Stevenson and associates, who recently acquired the Bamford coal mines located about 12 miles from Bessemer, which have been idle for some time past, have inaugurated active operations for production. A quantity of new mining machinery and equipment has been installed. The coal is of good grade, the veins running from 4 ft. to 5 ft. in thickness.

KENTUCKY

The West Virginia and Kentucky Coal Co., located on Smoot Creek, Letcher County, made its first shipment of coal on Monday, Sept. 9. This company leases from the Kentucky River Coal Corporation 1200 acres of coal, mining what is known locally as the Amburgy seam, the analysis being practically the same as the famous Elkhorn seam. The coal averages 5 ft. in thickness and is an excellent by-product coal. The town, yet to be named, consists of some 60 four-room houses, and a contract has been let for 50 more. All the houses are modern and up-to-date and modern "Sanisep" closets are installed in each house. The company starts out with shipments at the rate of 750 tons daily, which will be increased until 2000 tons per day has been reached. The officials of the company are Harry P. Jones, president; T. P. Jones, general manager; H. S. McClelland, secretary; J. B. Kennerly, treasurer.

ILLINOIS

Oglesby—Plans have been made for the temporary employment of the miners from the Oglesby Coal Co.'s plant, which was closed by an injunction secured by the Marquette Cement Manufacturing Co. For a few days the coal company asked its employees not to seek employment elsewhere, as it was believed that the injunction would only be temporary. It is hoped by the Oglesby Coal Co. that the men can secure employment in and near Oglesby, so that they will be enabled to reside there permanently.

Carlinville—Mine No. 4 of the Standard Oil Co. is being concreted. Excavations have been made 11 ft. below the coal for the concrete foundation. It will take at least 30 days to complete the work. Delays have been experienced in the arrival of the machinery, and it may be the first of the year before the hoisting engines and steel tipple are up. At Mine No. 3 the hoisting shaft is now down about 165 ft., and the material shaft is down about 60 ft. Work is progressing well on the power house and the dam.

Royalton—Twenty-three men are believed to have lost their lives in an explosion Saturday morning, Sept. 28, in the north mine of the Franklin Coal and Coke Co. Six bodies have been recovered. Rescue crews found it impossible to reach the portion of the mine where the others are supposed to have been at the time of the explosion, and the mine has been sealed to extinguish the fire. Among those who perished were Superintendent A. E. Capstick, Manager Theodore Helm, Pit Boss A. A. Capstick, Assistant Bosses Tony Heberer, Grover Capps and Harry McLaughlin, and Examiners William Ditterline, D. Alvis, Jettie Harris and J. Bothman. Fire was discovered in the mine by a watchman at 1 a. m. He gave the alarm and the officials and a number of miners went below. They were closing up entries, at 5 a. m., in an effort to confine the fire, when there was an explosion. A dozen men working near the shaft escaped. A rescue team arrived in a short time from Benton and by using smoke helmets were able to reach the bottom of the shaft; but it was 11 o'clock before the first bodies were found. Several hundred men are employed in the mine. Four years ago there was an explosion in the same mine which killed 52 men.

MISSOURI

Macon—The electrical equipment of the new mine of the Home Coal Co. has been installed and the mine will soon be ready for operation.

OKLAHOMA

Poteau—After being shut down for two months to enable the making of repairs, the mine of the Columbia Coal Mining Co., at Witteville, recently resumed operations with a force of 50 men.

Personals

J. I. Boyd on Oct. 1 resigned as purchasing agent of the United Coal Corporation, Pittsburgh, Penn.

W. C. Dodson of Paris, Ky., has taken charge of the Raymond Coal Co., having recently been appointed as manager.

Horace N. Trumbull, advertising manager of the SKF Ball Bearing Co., of Hartford, Conn., has entered the Reserve Officers' Training Camp at New Haven, Conn.

H. C. Steffey, of Akron, Ohio, has been appointed chief clerk to the general superintendent of the United Coal Corporation, with headquarters in the First National Bank Building, Pittsburgh, Penn., to succeed W. W. Oillett, promoted.

George A. Cokely, of Homer City, Penn., who was recently mentioned in these columns as having resigned his position as superintendent of the Tide Coal Mining Co., is still engaged in that capacity with the Tide Coal company. The announcement of his resignation was an error.

W. W. Oillett has been promoted from the position of chief clerk to the general superintendent of the United Coal Corporation, Pittsburgh, Penn., to the position of purchasing agent, succeeding J. I. Boyd, resigned. Mr. Gillett's headquarters will be in the First National Bank Building, Pittsburgh, Penn.

A. C. Emery having resigned as general purchasing agent of Thomas A. Edison, Inc., Orange, N. J., in order to devote his entire time to the Edison International Corporation, **William Dykeman** has, effective Oct. 1, been promoted and will assume the duties of general purchasing agent for the Thomas A. Edison industries.

Robert C. Byler, for nearly four years advertising production man for the SKF Ball Bearing Co., of Hartford, Conn., has been appointed advertising manager of the SKF Administrative Co., of New York City, and will direct the advertising of the SKF Ball Bearing Co., of Hartford the Hess-Bright Manufacturing Co., of Philadelphia, and the Atlas Ball Co., of the same city, all of which are controlled by the SKF Administrative Company.

George Watkins Evans, of Seattle, Wash., has been named a member of the Alaskan Engineering Commission. Mr. Evans is a well known coal-mining engineer, having specialized in that line of work for more than ten years in the Northwest. He has been the Government's representative in that field when investigations were first made of Alaskan coal, and supervised the getting out of the first test lots of the Bering River field for the Navy. In 1906 he surveyed the same field for the Guggenheims, and in 1913 surveyed the Matanuska field. He is the author of several books on coal mining and has been consulting engineer for many of the large coal operators of Washington, Canada and Alaska.

Obituary

Milton M. Baldwell, 44 years of age, who had for several years been connected with the Byrne & Speed Coal Co., of Louisville, Ky., and the Beaver Dam Coal Co., at Beaver Dam, Ky., died at his home in the latter city on Sept. 25.

William H. Bowser, 70 years old, member of the Bowser & Browning Coal Co., of Louisville, Ky., dropped dead of heart disease while standing on the rear platform of a Sixth St. car at Fifth and Main Sts., on Sept. 25. Mr. Bowser and George Avery Browning had been in the coal business at 136 South Sixth St. for a number of years, and at one time were large river coal handlers.

Trade Catalogs

U. S. G. Co.'s Graphite Products. United States Graphite Co., Saginaw, Mich. General Catalog No. 20. Pp. 64, 5½ x 8½ in., illustrated. Contains detailed information relative to lubricating graphite, greases, paints, etc. A group of photomicrographs and an interesting report of an exhaustive test made by the chief engineer of the Interborough Rapid Transit Co. of New York, are also included.

Type FK-20 Oil Circuit Breakers for Industrial Service. General Electric Co., Schenectady, N. Y. Bulletin 47,433. Pp. 16; 8 x 10½ in.; illustrated. The circuit breakers described and illustrated run up to 300 amp. and 2500 volts, and are intended primarily for use with induction motors in industrial applications. Under proper supervision they may be used in coal mines.

Industrial News

Sunbury, Penn.—The Anthracite Briquetting Co. has filed notice of an increase in its capitalization from $5000 to $150,000, the proceeds to be used, it is understood, for extensions.

Bristol, Va.—The Powell River Co. is said to be considering plans for the installation of a quantity of new mining machinery to practically double the present output of the plant.

New York, N. Y.—The Inter-City Fuel Co. has been incorporated with a capital of $200,00 to deal in fuel. T. L. and W. D. Eyre and J. H. Cullen, 350 Riverside Drive, are the incorporators.

Manchester, Ky.—The Manchester Coal Co. has filed articles of incorporation with a capital of $40,000 to operate coal properties in the Manchester district. Henry Miller, J. W. Lamb and C. W. White are the incorporators.

Ardmore, Okla.—The East Ardmore Coal Co. has filed articles of incorporation with a capital of $90,000 to develop coal properties in the East Ardmore section. J. T. Marrs, J. W. Weeks and W. S. Smith are the incorporators.

Manchester, Ky.—The Bruner Coal Co., recently incorporated, has perfected its organization plans and will commence operations at once on the development of 36 acres of coal lands near Manchester. G. B. Bruner is president.

Clarksville, Tenn.—The Clarksville Ice and Coal Co. has installed a two-ton Autocar equipped with automatic dumping device, for use in its coal department exclusively. This is the first coal truck placed in service in Clarksville.

Evarts, Ky.—The Upper Harlan Coal Co., of Harlan, which recently filed notice of an increase in its capital from $60,000 to $100,000, is planning for the immediate development of about 230 acres of coal properties in the Evarts district.

Charleston, W. Va.—Coal will be mined on Campbells Creek by J. T. Lightner, who is erecting a plant in connection with a mine he is opening where coal will be taken from the Coalburg seam. This new mine will be in operation by Oct. 10.

Wayne, West Va.—The Burke Coal Co., a Cincinnati concern, will operate in Wayne County on a small scale. This company was organized with a capital of $25,000 by A. J. Roberts, U. S. G. Anderson, Kyle Smith, F. C. Gruble and G. Earl.

Buffalo, N. Y.—Eugene J. Henry, formerly Lehigh Valley lake agent at Chicago, has been appointed government supervisor of the Lehigh Valley coal and package freight lake line and lake-and-rail business at eastern lake ports, with headquarters here.

Philadelphia, Penn.—The Fernwood Coal Co. has been incorporated under Delaware laws with a capital of $200,000 to engage in general coal-mining operations. F. B. Hansell, Philadelphia; J. V. Pimm and S. C. Seymour, Camden, N. J., are the incorporators.

Birmingham, Ala.—The DeBardeleben Coal Co. will move its main offices to Sipsey, Ala., where its mines are located. The Empire Coal Co. will also have its head offices at Empire, Ala., where its mines and coke ovens are in operation. Both of these companies have heretofore maintained their general offices in Birmingham.

Wurtland, Ky.—The Wurtland Coal Co. has been incorporated with a capital of $25,000 to operate coal properties in the vicinity of Wurtland. Wayne Calvin, Wurtland, A. F. Lamaster and G. Washington, Russell, Ky., are the principal incorporators.

Big Stone Gap, Va.—The Liberty Coal and Coke Co. has been incorporated with a capital of $1,200,000 to engage in coal-mining operations in the Big Stone Gap district. S. Thurston Dallard and A. C. Stith, both of Louisville, Ky., are the principal incorporators.

Harrisburg, Penn.—Announcement has been made by the Gamble Briquette Co. that a new size of briquette coal has been evolved by its experts, suitable for use in basket grates. The company's products have been in great demand due to the present scarcity of coal.

Pennington, Va.—The Penn-Lee Coal Co., recently incorporated with a capital of $90,000, is planning to commence operations at once on the development of about 125 acres of coal properties in the Pennington Gap section to have a capacity of about 250 tons daily.

Beckley, W. Va.—Progress is being made on the construction of a plant by the Ingram Branch Coal Co. on the Virginian Ry. in Raleigh County for the development of a tract of 3200 acres under lease. C. H. Mead of this city is one of those largely interested in the company.

Pittsburgh, Penn.—The Pittsburgh Coal Co. has disposed of a tract of about 17 acres of property fronting on the Monongahela River at Dravosburg and extending back to Washington Road to the National Tube Co., Pittsburgh, for a consideration said to be in the neighborhood of $100,000.

Fairmont, W. Va.—Operations in Monongalia County on a large scale will be undertaken by the Diamond Coal Co., of Fairmont, which has been organized with a capital of $200,000. Identified with the new corporation are: A. P. Brady, Warder Cresson, W. E. Engle, Henry M. Schrader and H. W. Showalter.

Charleston, W. Va.—The Buffalo-Kanawha Coal Co., recently organized, is planning to commence operations at an early date on the development of approximately 750 acres of coal properties in the Malden district, to have an initial capacity of 200 tons daily. J. W. Johnson is president; G. A. Corson is vice-president.

Morgantown, W. Va.—The Scott's Run Coal Operators' Association, composed of owners of mines in Monongalia County, has taken up the question of an excessive arbitrary freight rate charged on all coal loaded by mines located on the Morgantown & Wheeling Ry. and a committee of seven operators has been appointed to handle this matter.

New York, N. Y.—Exports of coal through the Port of New York during the month of August amounted to 10,460 tons of anthracite, valued at $72,264; 10,149 tons of butuminous, valued at $72,612; and 333 tons of coke, valued at $9032. Of the anthracite, 65,845 tons went to Canada, and of the bituminous, 65,578 tons went to Brazil.

Fairmont, W. Va.—The Dawson-Connellsville Collieries Co. has been formed to take over certain coal lands already under development. The company will carry on operations not only in Marion County but elsewhere in the state, having been capitalized at $120,000 by Carl Riggs, G. C. Wedding, W. M. Kennedy, E. F. Hartley and H. H. Rose.

New York, N. Y.—State Fuel Administrator Cooke has announced the appointment of H. E. Willer as manager of bituminous distribution for the State of New York, and the appointment of D. T. Davis, of Davis, Symmes & Schreiber, 55 Liberty St., as counsel for the State Administration. Mr. Willer succeeds Ellery B. Gordon, who resigned.

Dallas, Tex.—Lignite production and consumption will be given marked impetus in Texas by the reduced freight rates granted for this commodity, as asked by the lignite producers some time ago., Texas produces much lignite which is being used for fuel in the boilers of many industries, such as electric light plants, cotton gins, oil mills, cotton compresses, etc.

Louisville, Ky.—The Smith-Gardner Co., of Louisville, Ky., which up to the present time has been doing a purchasing or jobbing business, is entering the producing field, having recently secured mining property, which is being developed in the Straight Creek field near Pineville, Ky. The company expects to start shipments in 30 days with an initial output of about three cars.

Denver, Colo.—Colorado's coal production for the first seven months of 1918 exceeded by 394,559 tons the production for the corresponding period of last year, the total amount from all the mines of the state up to Aug. 1, 1918, being 8,649,467 tons. The latest report shows that in August 1,124,067 tons were produced from the 222 mines in operation, with 13,867 men employed.

Fairmont, W. Va.—Team track loaders of the Fairmont section will soon have an adequate car supply if plans now under consideration mature, as they are expected to. The plan is to change the zone for shipments of box car coal to permit shipment to be made to points in Ohio, Indiana and Pennsylvania. This will permit the loading of empty box cars being returned to the west for shipments of foodstuffs to the eastern ports.

Monterey, Tenn.—The Tennessee Coal Co., recently incorporated with a capital of $100,000, has perfected its organization, and has had plans completed for the immediate development of approximately 2500 acres of coal property in the vicinity of Monterey, to have an initial capacity of about 15 carloads daily. The company has already purchased the entire mining equipment for operation. M. M. Whittaker is president and manager.

Charleston, W. Va.—Fifty thousand dollars will be expended by the Columbia Coal Co. of Charleston, in the development of a bed of coal in Malden District of Kanawha County. The company has an authorized capital of $90,000, having been organized by Charles A. Smith, Herbert Hannigan, S. G. Smith, R. M. Fountain and C. H. Hetzel, all of Charleston. The new company will take coal from the No. 2 gas seam on Campbell's Creek. Permission to install a siding has been granted.

Toledo, Ohio—Considerable activity was shown during the week ending Sept. 28 at the Toledo docks, showing a good movement of coal from Ohio and West Virginia mines to the Northwest. During the week the Toledo & Ohio Central docks loaded 85,000 tons as compared with 73,000 tons during the previous week, making a total of 1,607,000 tons for the season. The Hocking Valley docks loaded 200,638 tons as compared with 190,333 tons the previous week, making a total of 3,687,679 tons for the season.

Springfield, Ill.—The annual report of Evan John, director of the state department of mines and minerals, shows that coal production in Illinois increased 10,995,982 tons in the fiscal year of 1918 as compared with the next previous year. The report shows that a total of 967 coal mines in Illinois produced 89,979,469 tons of coal as compared with 78,933,487 in 1917. The figures are compiled from 370 shipping mines in the state and 597 local mines. A total of 91,372 men were employed in Illinois as compared with 80,893 in the previous year.

Oklahoma City, Okla.—The work of appraising the Indian lands in the Choctaw and Chickasaw Nations of Oklahoma has been completed, and these lands will be offered for sale during October. These lands lie in Pittsburg, Pushmataha, LeFlore, Latimer, Coal, Haskell, Murray, Garvin and Grady counties, and amount to approximately 14,400 acres, of which 6700 acres constitute the surface of unallotted coal and asphalt lands. These coal lands are underlaid with some of the richest coal veins in Oklahoma, as yet wholly undeveloped. All coal and asphalt under the lands of the segregated area is not to be sold with the surface, but is reserved by the Government. All other tracts will be sold without reservation.

New York, N. Y.—Among the contributors to the coal trade allotment to the Fourth Liberty Loan are: Pennsylvania Coal Co. and the Hillside Coal Co., $1,200,000; Madeira, Hill & Co., $160,000; Pennsylvania Coal and Coke Corporation, $110,000; F. A. Potts & Co., $50,000; Lehigh Valley Coal Co., $50,000; Willard, Sutherland & Co., $40,000; Thorne, Neale & Co., $30,000; Burns Bros., $100,000; Mill Creek Coal Co., $60,000; M. F. Burns, $25,000; Vinton Collieries Co., $60,000. Delaware, Lackawanna & Western Coal Co., $1,000,000; Lehigh Valley Coal Sales Co., $1,000,000; Pennsylvania Coal Co., $300,000; Hillside Coal and Iron Co., $100,000; Joseph B. Dickson, $65,000; Jesse L. Eddy, $65,000; Price-Pancoast Coal Co., $60,000, and West End Colliery Co., $60,000.

MARKET DEPARTMENT

Weekly Review

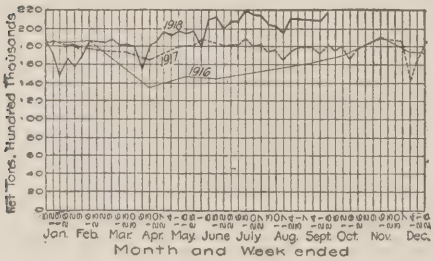
Coal Industry Now on War Basis—With All Demands Known, Fuel Administration Calls for Definite Tonnages of Anthracite and Bituminous—Domestic Demand Urgent, While Bottom Has Dropped Out of Market for Steam Sizes of Anthracite

NO RED-BLOODED American can read of the heroic exploits of our soldier lads across the sea without a thrill of pride. Only yesterday, as it were, a people devoted to peace and following peaceful pursuits, we have converted our plowshares into battle-axes and demonstrated to the disciples of *Kultur* that the spirit of a free nation can surmount all obstacles when it is actuated by high ideals.

To the end that humankind shall continue down the ages unfettered and unshackled, the coal mining industry, in common with other fields of endeavor, has been placed on a war basis. No longer will it be possible for slackers in the mining ranks to lay down on their jobs. The Production Department of the Federal Fuel Administration has divided the coal producing facilities of the country in such a manner that not even one single individual embraced therein will escape questioning if he fails to account for the full measure of the task allotted him.

That a maximum production of coal is an important factor in the war program is a matter of universal knowledge. The necessity for an enlarged supply of bituminous coal is particularly pressing. The Fuel Administration is no longer concerned about the coal situation except as it affects the output of iron and steel needed for munitions and other war purposes. It is either shells or human lives, the lives of our boys at the firing line, and the output required of the soft coal mines between now and Mar. 31, 1919, is 12,234,000 net tons a week. If this average tonnage can be maintained for the next five months, the bunker, naval and other oversea requirements will be met. For the week ended Sept. 28 (the latest statistics available) the production of soft coal was 700,000 tons above the average mentioned, as the total quantity mined during that week was 13,043 000 net tons.

The anthracite mines, too, have been asked to increase production, because of the expanding war program of the nation and to assure adequate supplies of fuel for American industries and American homes. The hard-coal mines are called on to furnish 2,030,000 net tons a week for the next five months. With a shortage of labor already existing in the anthracite regions, it will require strenuous efforts on the part of those engaged in this branch of the industry to meet the call. For the week ended Sept 28 the production of anthracite is estimated at 2,071,000 net tons, which is also well above the quantity demanded.



Market conditions, insofar as domestic demand is concerned, are active. The coming of colder weather has witnessed an urgent demand for fuel from household consumers. The influenza epidemic, too, has been responsible for the starting of fires in many homes much earlier than usual, and dealers are being besieged by consumers whose bins are bare of coal. The stove and chestnut sizes of anthracite are in strong demand, and calls for egg coal are also becoming more frequent. The outstanding feature of the market is the collapse in the demand for the steam sizes of anthracite, and several washeries are reported as about to close down for lack of orders.

Cities located near the mines, such as New York and Philadelphia, for example, are receiving only light shipments of anthracite, as a concentrated effort is being made to take care of the outlying sections before winter ties up transportation facilities. Fuel administrators are hopeful, however, that by December every home will have some coal, and dealers in many localities have been notified not to deliver any more coal to those who already have a supply.

It has been definitely decided that the Great Lakes shipping season will be held open until the last possible moment this year, and operators who were rather pessimistic over the outlook for the northwest are now more optimistic. The lake shipments for the season to Oct. 1 are roughly 800,000 to 850,000 tons behind schedule.

WEEKLY COAL PRODUCTION

Bituminous coal production during the week ended Sept. 28 not only exceeded 13,000,000 net tons but also records the third successive week of increased production. The output during the current week (including lignite, and coal made into coke) is estimated at 13,043,000 net tons, an increase over the week preceding of 325,000 net tons or 2.5 per cent., and over the corresponding period of 1917 of 1,863,000 net tons, or 16.7 per cent. The average production per working day, during the week of Sept. 28, is estimated at 2,174.000 net tons, 9 per cent. in excess of the average daily production for the coal year to date and 6.7

per cent. in excess of the average daily requirements during the balance of the coal year to make up the deficit.

During the past six summer months, or the first half of the coal year, production of bituminous coal is estimated at 311,216,000 net tons. This output, which is 33,418,000 net tons, or 12 per cent. in excess of the production during the same period of 1917, falls short of requirements during the current year to date by 10,897,000 net tons, or 3.4 per cent., the increase in requirements this period over the output for the same period last year amounting to 44,315,000 net tons, or approximately 16 per cent.

The production of anthracite in the United States during the week ended Sept. 28 is estimated at 2,071,000 net tons, an increase over the week preceding of 224,000 net tons, or 12.1 per cent., and over the corresponding week of last year of 65,000 net tons, or 3.2 per cent. The average daily production during the current week is estimated at 345,000 net tons as against 338,000 net tons during the coal year to date and as compared with 330.000 net tons during the same period of 1917. Total production from Apr. 1 to Sept. 28 is estimated at 51.651,000 net tons, an increase over 1917 of 1,072,000 net tons, or 2.1 per cent.

Carrier's reports show increased shipments from all districts during the week ended Sept. 28, compared with the week preceding, with the exception of the districts including Cumberland, Piedmont and Somerset, and Tennessee and Kentucky. The decrease in the Cumberland, Piedmont and Somerset district was slight, while Tennessee and Kentucky shipments declined 3.5 per cent. Material improvement occurred in central Pennsylvania, where shipments increased 1653 cars, or 4.5 per cent.; in Northeastern Kentucky and the high volatile and smokeless fields of West Virginia, where shipments increased 927 cars, or 3.2 per cent.; in the district including Illinois, Indiana and western Kentucky, where shipments increased 1955 carloads, or 3.8 per cent.; and the district including Iowa, Texas and Southwest States, where shipments increased 656 carloads, or 4.6 per cent.

Bituminous coal dumped at lake ports (including vessel fuel) during the week ended Sept. 28 is estimated at 1,200.672 net tons, an increase over the preceding week of 7.8 per cent. Compared with the weekly average of the months of July, August and September, the current week's shipments show a gain of 11.7 per cent.

New England shipments of bituminous coal fell considerably during the week ended Sept. 28. Estimates place the total of bituminous coal to New England during this week at 450.766 net tons, a decrease compared with the week preceding of 14.2 per cent. Of this total, rail receipts through the gateways declined 7.1 per cent. compared with the week preceding, the total tidewater shipments 18.1 per cent. A considerable decrease occurred in shipments from all harbors, New York and Philadelphia falling behind 14.8 per cent., Baltimore 9.8 per cent. and Hampton Roads 22.6 per cent. Shipments by rail and from each harbor also fell considerably behind the weekly average during the coal year to date.

Shipments of bituminous coal from tidewater harbors, during the week ended Saturday morning, Sept. 28, are estimated at 916,793 net tons, an increase over the week preceding of 1.8 per cent. All North Atlantic harbors report improvement in the week's shipments, the New York and Philadelphia increase amounting to 4.4 per cent. and the Baltimore increase to 13.8 per cent. Shipments from Hampton Roads declined slightly—1 per cent. Shipments during the week from each harbor also exceeded the weekly average for the coal year to date.

Beehive Coke—Production of beehive coke in the United States during the week ended Sept. 28 was approximately the same as that reported in the week preceding. Preliminary estimates place production during this week at 612,000 net tons as against 614,000 net tons for the week of Sept. 21, the average daily production during each of the two weeks amounting to 102,000 net tons. The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production during the week ended Sept. 28 at 383,746 net tons, and the operation of their plants at 76.4 per cent. of their full time as against 76.7 per cent. during the week preceding. Operating conditions varied but slightly during the week, yard labor shortage, as in preceding weeks, being the factor which liimted production.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended Sept. 7	Sept. 14	Sept. 21	Sept. 28
Bituminois shipments, 123 roads	195,367	223,131	223,981*	230,251†
Anthracite shipments, 9 roads	32,234	40,699	36,859	40,524

*Revised from last report. †Subject to revision.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running well ahead of the heavy shipments of the same week in 1917. The volume of road sales for immediate and spring delivery is in excess of the corresponding week of last year. A smaller number of customers was in the market. Collections continue excellent.

Dry Goods Economist—Reports from various sections are to the effect that in department stores the demand for seasonable goods continues good. Collections are excellent and money appears plentiful despite the demand caused by the drive for the Fourth Liberty Loan. Labor appears

more free from unrest due, undoubtedly, to the feeling that the forthcoming draft of young men and those above 31 years old raises questions that must take precedence over all others affecting the working man for the time being.

The Iron Age—Steel output in September with two days less has exceeded that of August. A marked improvement in the quality of coke is reported and some headway is thus being made on the pledge of the trade to increase output 10 per cent. The Carnegie Steel Co. maintained this week its 92 per cent. of furnace capacity in blast last week and its rate of ingot production was 97.8 per cent. against 97.5 per cent. for the previous week. The industry enters October, always a good month, under generally auspicious conditions.

American Wool and Cotton Reporter—The Government has taken up the matter of procuring wool from Australia as the raw material from that market is to be obtained only through negotiation with the British Government. The influenza epidemic has had its effect on the cotton mills, 1600 looms out of 6000 having stopped operations at the Tremont and Suffolk mills because of this disease. Perhaps the one thing of note which has taken place in cotton goods during the past week has been the willingness of manufacturers and merchants to take some business following the announcements that there would be no further determination of prices until Nov. 16.

Bradstreet's—Government work, further adjustments of industry to war-time needs, and the Liberty Loan drive overshadows everything else, but in between these activities a large volume of business on domestic account is passing, three-fourths of the country being supremely active, and, in addition, the glowing news from the war fronts has evoked attention in stock market circles. In the east, however, activities flowing out of the campaign to make the Fourth Liberty Loan preëminently successful have produced a tendency to economize, which hampers business to some extent, while the ravages of influenza have held up trading in important sections of New England, as well as operations at many eastern shipyards and factories.

Atlantic Seaboard

BOSTON

While receipts continue to sag, New England is taking account of stock. Situation easy as to current needs but anxiety over future supplies is evident. Meanwhile buyers show no disposition to order box cars to the extent that might be supposed. The same consignees are most solicitious lest shipments be discontinued through ordinary trade channels. Influenza epidemic spreads to central Pennsylvania. Steel program dominates all other requirements except for bunker and naval use. Hampton Roads situation shows no improvement. The calls of Pocahontas coal moves to other markets. No redress as yet for shippers whose transportation arrangements have to be made in advance of receipts at the piers. Shipments from Baltimore and Philadelphia considerably reduced. Movement on New York's ports not much increased. Connecticut plants better stocked than 30 days ago. Anthracite shows little change. Too early yet to make comment on "free anthracite" shipped to Mr. Storrow's order.

Bituminous—It can now be said that New England industries have practically four months' supply in reserve, although some of the railroads and other large utilities would not make so favorable a showing. The schedule for all-rail shipments has been pretty well maintained as any examination of the figures will disclose. To Oct. 1 actual receipts through the five New England gateways were close to 5,600,000 tons, or about 400,000 tons less than the 60 per cent of the 10,000,000 tons that were to be moved in this direction between Apr. 1 and Oct. 1. By water the receipts have been considerably in arrears. The program called for around 12,000,000 tons for the six months, but actual deliveries were less than 9,000,000. The first half-year closed therefore with a shortage of something over 3,000,000 tons as compared with schedule.

The prospect therefore for shipments from central Pennsylvania the next few months becomes of especial interest; 83.5 per cent. of total all-rail deliveries to New England were scheduled to come from that one district and a brief analysis of receipts from that quarter now has a bearing on the supply available later on. The following table shows how evenly shipments all-rail from central Pennsylvania (wagon-coal not included) have kept up, comparing the week ended July 27 with that ended on Sept. 21:

No. of cars	July 27	Sept. 21
New England railroads..	1130	1361
New England commercial	2506	2308
Total	3636	3669

This, then, for New England is an encouraging showing. During September largely increased requisitions were made for byproduct use, to some extent in central Pensylvania, and yet the movement keeps up with fair regularity. The sag is apparent in other districts, but so far as central Pennsylvania is concerned this tertory has less occasion to worry.

Undeniably the situation is easy here as to current needs. Practically all the industries and power plants are well stocked, and to such extent is this true that buyers are getting particular about quality and the way in which deliveries are made. Among larger buyers, especially those more dependent upon water-borne coal, there is anxiety over future shipments, but yet not enough to make them eager to take what wagon-coal, for instance, is now offering. The 75c. extra for closed equipment is enough to turn the scale.

At Hampton Roads there are still serious cases of over-detention to bottoms waiting for coal for New England. There are today barges which have been two weeks awaiting coal, and meanwhile Government requirements are of course being supplied from day to day. Pocahontas coal, largely because of its low price, is moving very largely to byproduct plants and for coking purposes, while New River is practically free for Government, bunker and for commercial use in New England. For the Pocahontas transshipper who is obliged to arrange for his water transportation considerably in advance there is no redress when his coal is ordered away to other markets. He simply waits patiently for more of his coal to reach the piers, pays the demurrage and either hopes or expects the ultimate consignee eventually to make good the extra expense.

Shipments from Baltimore and from Philadelphia have sloped off to such extent that movement to those piers has been curtailed quite radically. So little coal has been dumped at the Philadelphia piers of late that coal trains have actually been stored in transit on account of yard accumulation. One effect has been a discontinuance of shipments from the mines to that quarter.

Another change is noted in Mr. Storrow's staff at the State House. G. G. Wolkins, who has been bituminous distributor all-rail since Jan. 4, has now returned to his regular work with Hanson & Parker, Ltd., who had given his services. Mr. Wolkins was expecting to continue his efforts through the coming winter, but the New England Fuel Administrator considered it suitable to assign the work to someone else. This change, following so closely on the similar experience of Augustus S. Cobb, who organized for Mr. Storrow the conservation department for New England, has caused comment in the trade. Mr. Cobb was promptly invited to Washington to take charge of the same work for the whole country that previously he had charge of only in New England.

Anthracite—There is little change in the situation on domestic sizes. Shipments are disappointing and retailers grow restive as the season advances. In many towns there are hundreds and thousands of orders on file from householders who have not yet had deliveries of any kind. It is likely that there will be some serious situations to deal with when cold weather sets in.

It is too early yet to comment on the distribution of "Storrow anthracite" which is now coming forward. The fuel authorities who are supervising this distribution certainly have their hands full.

PHILADELPHIA

Anthracite demand heavy due to weather and grip epidemic. Shipments moderate. Improvement promised this month, but dealers doubtful. Yard labor problem grows more serious. New conservation measures effective. No decision on wage problem. Steam coal market slows down. Bituminous up to average of past month or two. Coal well distributed.

Anthracite—Practically all householders got their fires under way this week due to some chilly days which made a little warmth comfortable. Also due to the influenza epidemic, most people who from measures of economy even delay this act until much later in the season, called upon their dealers for at least sufficient coal to get their furnaces going. The fuel administration in order to meet this situation made a ruling that any home where there was a case of the sickness should be served immediately with fuel. However, this extra use of coal was more than offset by the closing of all the schools, theaters, churches and all places given over to public gatherings. Unfortunately, the shipments continue somewhat light locally, although there are a number of the larger dealers who have quite a stock; but every cold day brings hurried calls for it. Stove and chestnut are, as always, in very active demand, with egg also showing considerable life recently. Pea coal is easier than for some time, although the demand during the past few days has been greatly increased.

In the way of shipments it can be said that the largest company shipped less coal to this market during September than any month this year. It is understood that in the same period it increased its shipments to New England almost 100 per cent. and the southern territory, particularly Baltimore and Washington, fared almost as well. This, together with several cold days, made the first week of the current month one of turmoil for both the shipper and dealer. To offset the unfavorable shipping conditions of this company, another of the larger shippers seemed to turn its attention to this market, and for five days shipped as much coal here each day as it had shipped during any one week for several months. This materially helped the situation.

The dealers in the suburbs are promised heavy shipments during October, but at this writing the dealers in the city proper do not know what to expect. It is estimated, however, that real substantial shipments to the rail yards are not to be looked for before November or perhaps December. It is apparently the intention of shippers to complete all obligations to the water yards first.

Probably the outstanding feature of the present market is the collapse in the demand for steam sizes. Commencing with No. 1 buckwheat, on which the Pennsylvania Fuel Administrator some days ago removed for the period of 30 days the necessity for securing exemption orders, down to culm, the demand is less active than for many months. As a representative of one of the large interests here expresses it, buckwheat and rice are free, barley is dead and culm is not salable.. It is understood that several washeries are about to close down for want of orders. The heavier receipts of bituminous have had their effect, also the fact that little has so far been used in the hotels, apartment houses, department stores and office buildings.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken.....	$4.90	$6.25	Buckwheat..	$3.40	$4.45
Egg.....	4.80	6.15	Rice.....	2.90	3.80
Stove.....	5.05	6.40	Boiler.....	2.70	3.70
Nut.....	5.15	6.50	Barley.....	2.40	3.30
Pea.....	3.75	5.00	Culm.....	1.25	2.15

Bituminous—A fair tonnage has been reaching here for the past ten days or two weeks, but it is generally conceded this is much less than the quantity necessary to maintain the plants throughout the coming winter. One thing is certain, however, and that is the tonnage has never been more equitably distributed. The big users, including all utility plants, many of whom have 60 day's supply, are completely shut off for the time being, while the small plants are beginning to exhibit appreciable stocks.

Car supply continues to range between 40 per cent and 65 per cent of working capacity of the mines, with rail movement good, as coal is prompt in reaching market after it is consigned. Shippers continue to urge on rail interests the necessity for a better car allotment, but there still exists a wide variance of opinion between the two as to the necessity.

The trade is still considerably interested in the investigations being made by the administration as to the irregularities in price charged against some of the brokerage houses. With the fining of several recently there are rumors of still other important cases pending.

NEW YORK

Lack of supplies chief complaint of dealers. Dumpings at the local docks show decrease. The trade gets broken coal instead of egg, but do no grumbling. Small sizes become burden and indications point to pooling of these coals. Bituminous situation improves and is in good shape. Bunker coals increase is supply.

Anthracite—Continued lack of supplies is causing much trouble in trade circles.

Dealers here are being hounded for coal, but their only answer lies in the slowness with which shipments are coming to this market. The reports of increased production and shipments do not give much encouragement to the trade here, inasmuch as the Anthracite Committee has recently discontinued deliveries to various communities throughout New England and in this state, indicating that coal has been sent to these places in good volume. Not much consolation can be found in the reports of dumpings at the local docks, which have been showing a gradual decrease week by week and month by month. For the week ending Oct. 4 the cars dumped were 6557, while for the previous week they were 6727. There is therefore a decrease of 170 cars, quite a deficiency when one considers the season of the year. For last month the dumpings were 27,944 cars as compared with 32,494 cars in August, 31,284 cars in July and 30,719 cars in June.

It is likely that the market is still feeling the effects of the suspension in the anthracite fields during the week ending Sept. 21, which resulted in a loss of 11.3 per cent. in production, or 1,847,000 tons produced as compared with 2,088,000 tons the previous week.

There is a steady demand here for all domestic coals. Recently there has been much broken coal sent to dealers who have asked for egg, and most buyers have been asked to take a portion of their shipment in the smaller sizes. This has naturally burdened the retailers with an over-abundance of these sizes, which it is difficult for them to dispose of unless they are able to secure bituminous to sell at the same time.

Some of the docks have been over-stocked with buckwheat and the smaller sizes, with the result that embargoes have been issued several independent producers and shippers. There is a movement on foot to provide for the storing and pooling of these coals, the one obstacle to prevent it being the mixing of the good and bad grades.

Mayor Hylan proposes to have the police repeat their work of last winter by making a house to house canvass for the purpose of obtaining first-hand information as to the amount of coal on hand. This canvass is not to be made until after the finish of the present Liberty Loan Drive.

The State Fuel Administration has fixed the allotment of anthracite for Greater New York at approximately 8,000,000 tons of sizes between broken and pea, inclusive; a trifle over 11 per cent. over the shipments of these sizes in the coal year 1916-1917.

The Brooklyn retail dealers are considering the advisability of inducing customers to have their coal dumped on the sidewalks, the customer to put it into the bins and to receive a reduction of 35c. per ton from the present retail prices. The dealers complain of a lack of help and say they would be enabled to deliver much more coal than at present.

Current quotations, per gross ton, f.o.b. tidewater, at the lower ports are as follows:

Circular	Individual	Circular	Individual
Broken..$6.75	$7.50	Buck.. $5.10	$5.90
Egg.... 6.65	7.40	Rice.... 4.65	5.10
Stove... 6.90	7.65	Barley.. 4.15	4.30
Chestnut 7.00	7.75	Boiler.. 4.60	
Pea... 5.50	6.25		

Bituminous—The situation is better than for many weeks. More coal is available and the trade appears to be on easy street. While the local dumpings for the week ending Oct. 4 amounted to only 6666 cars as against 7059 cars the previous week, the demand was not as heavy, due to the fact that shipments to non-essential industrials have been curtailed if not altogether suspended. For the month of September the dumpings were 30,440 cars as against 31,297 for August, 30,372 for July and 31,129 for June.

There has been an increase in bunker coal production, with the result that vessels are being more rapidly coaled and the near-shortage of these coals has disappeared.

Current quotations, based on Government prices at the mines, net ton, f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack...	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

BALTIMORE

Continued liberal supply of bituminous here encourages more consumers to take only open-top cars, the result being box-car orders are frequently much over-filled in order to clean up. Hard-coal situation so acute here that Washington decides to make an investigation.

Bituminous—A liberal flow of soft coal is coming in, but much of it cannot be classed as desirable. This easy movement has made the entire market a little soft, with the result that a number of consumers are refusing to take box cars of coal and are willing to live on the small surplusages they have accumulated while waiting for open-car shipments. There have been quite a few reports recently that those willing to take box-car coal have been over-supplied, and that when an order is placed for that kind of coal it has not been infrequent to see it doubled or even trebled in delivery. This is probably due to the fact that for the moment the fuel administration in a number of sections has more loaded box-car coal on its hands for disposal than it has customers, and in order to clean up and prevent confusion is filling all such orders with a more than liberal hand.

Anthracite—The hard-coal situation in this city is serious. Coal men here claim it is worse than in any of the large cities of the eastern seaboard. Estimates have been made by some of the fuel administration officers here that there are 30,000 homes in Baltimore still lacking hard-coal supplies; while many retail coal men say the number exceeds 40,000. The light supplies have prevented any catch-up on the more than 200,000 tons of unfilled orders that have been on the books here for several months, while hundreds of persons are going from dealer to dealer only to be told that they can book no more orders.

A. S. Learoyd, anthracite distributor of the Federal Administration, arrived in the city last Saturday and made a personal investigation of the situation. While it is now rather late to hope to bring full relief, the strong hope is expressed that additional shipments will be sent to Baltimore to prevent real suffering when cold weather sets in.

The following bushel and peck rates have been established for this city by the Maryland Fuel Administration: Prepared sizes, per bushel of 80 lb.—at the yard, 45c.; when delivered to house, 50c. Pea coal, per bushel of 80 lb.—at the yard, 35c.; when delivered at house, 40c.; prepared sizes, per peck, 13c.; pea coal, per peck, 10c.

Lake Markets

PITTSBURGH

Car supplies continue fairly good. Labor insufficient for full operation. New car distribution system causes discussion.

Little if any production is being lost on account of car shortage and output is approximately up to labor supply. Production is short of capacity, but it is a matter of opinion whether the gap between mine capacity and actual production should be ascribed to labor shortage or to car shortage.

The revolutionary method of rating mines for car supply introduced by the Fuel Administration has been much discussed in coal circles. Each operator seems to look upon the change from the personal viewpoint, whether it will operate to the advantage or disadvantage of his own mine. The essence of the new system is that the capacity of the mine is to be determined afresh each month, by making the proportion of its rating to its production equal to proportion between full working time and the time actually worked.

Practice among railroads has not been uniform, various methods having been used in the past. The system of the Pennsylvania was quite complicated and on the whole operators considered it fair. Some roads have been rather careless about their ratings. One feature of the change, affecting but a few mines, is very important, that applying to mines served by more than one road. There have been a few somewhat notorious cases of mines thus located getting a much larger proportion of cars than other mines.

There are practically no open market transactions, nearly all the coal produced going out on contracts or allocations. The national association of coal brokers is making a new drive for membership and desires to include coke brokers. The brokers are doing scarcely any business these days. The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine. Pittsburgh district, with 15c. brokerage allowed to be charged by regular brokers to consumers or retail dealers.

BUFFALO

Trying to increase production. Plenty of cars; labor not so certain. Cutting out unnecessary consumers and suspending those with a supply. Anthracite by lake moving as usual, in Buffalo short.

Bituminous—The effort to get out an additional amount of coal is the rule on the part of all producing interests. Some of them are nervous and say that they do not see how the former pace can be kept through October as the men are not eager to come back to the mines with the return of fall weather.

The local situation is somewhat easier, and the issuing to shippers of a long list of consumers who are to be given no coal till further notice merely means that they have a supply and can wait awhile. Of course, they will take in an over-supply if they can get it. Often there comes in a complaint that this or that concern, perhaps a city water-works, is nearly out; but it remains to be reported that anything vital has been left unsupplied.

The jobber still sees his business lagging. He is of the opinion that the Government zonal managers will finally absorb most of the trade left to the jobber and claims that it is fast going now. Meanwhile the bituminous prices are holding as formerly, being $4.65 for Allegheny Valley thin vein, $4.45 for Pittsburgh lump, $4.20 for Pittsburgh mine-run and slack, $5.85 for smithing and smokeless and $5.60 to $6.10 for cannel, all per net ton, f.o.b. Buffalo.

Anthracite—The situation does not change materially. Distributors are sure that the city supply is running down, but wholesalers claim that they have turned over enough of what has come here to keep up the allotment, and a report comes from the state fuel office that every effort is making to provide this county with what has been promised it. At the same time the consumer will never cease to claim that the situation is critical till a good winter's supply has been delivered to everybody.

Lake shipments continue fair, being for the week 109,900 tons, of which 53,000 tons cleared for Duluth and Superior, 22,500 tons for Fort William, 20,500 tons for Milwaukee, 10,000 tons for Chicago, 2900 tons for the Sault, and 1000 tons for Depere. Freight rates continue strong at $1 for Depere and the Sault, 60 to 65c. for Chicago, 55c. for Milwaukee and 48c. for Duluth and Fort William.

TORONTO

Conditions growing very serious. Large number of consumers destitute of fuel. Increasing use of soft coal. Regulations being strictly enforced. Fuel made from garbage and waste material.

The coal situation has become more serious, the setting in of cold weather earlier than usual finding a large percentage of consumers entirely unprepared for the winter. Upwards of 9000 citizens have reported to the City Fuel Controller that they are absolutely without fuel. The more necessitous cases are being supplied as rapidly as possible, delivery of orders to those having partial supplies being suspended in the meantime. Soft coal is being laid in in increasing quantities by those unable to obtain anthracite.

R. Howe Smith, Ontario Fuel Administrator, states that in the allotment of coal originally made to Ontario there was a shortage, as compared with last year, of 400,000 tons of anthracite. With the coming of cold weather and prospective transportation congestion this shortage will possibly be increased to 500,000 tons, which will be most severely felt by the municipalities which have failed to comply with the regulations for the stabilization and distribution of their local supply. Some months ago the Provincial Fuel Administrator requested every municipality to appoint a local fuel administrator, but so far only 160 communities, or 18 per cent. of the total have done so. Circulars were also sent to coal dealers asking that figures be returned showing their requirements based on the consumption of 1916, but this request was in many cases ignored. As a result the Canadian Fuel Controller in his negotiations with Washington, did not take the possible consumption in their communities into his calculations when asking for the Canadian allotment. It is possible that these communities may have to go without coal, and they will certainly have to take a larger proportion of bituminous than the places where the dealers have made an effort to coöperate with the Fuel Administrator. It is imperative that municipalities which have not yet appointed their local fuel controller take immediate action, the intention of the Provincial Fuel Administrator being not to consider requests for relief unless from the local fuel controller.

CLEVELAND

With the exception of the domestic user, the position of every class of coal consumer has improved to a marked extent. Newly formed plans for unloading coal at the head of the Great Lakes have caused some dissatisfaction among operators. The labor situation at the mines constantly is growing more acute, but production has been on the upgrade recently.

Bituminous—Attention of operators in the No. 8 district of southern Ohio is now focused on the labor situation. For some few weeks labor has been going from bad to worse, but the evil has not been so apparent because improved car supply made up for the deficiency. But the point has now been reached, operators say, where they cannot blind themselves to the facts any longer. Cutters, in particular, have become slothful, and in some cases have refused to work more than four hours a day. As a result, some mines are losing from 25 to 30 per cent. of production, and the assistance of the Federal Fuel Administration is being sought.

Just now more coal is going to industrial plants than for the past few weeks, operators say, and stock piles seem as large as ever. The coal that is going to retailers, however, does not average more than 15 to 20 per cent. of their requirements. The extent of the fuel shortage in Ohio this winter depends entirely upon the amount of Ohio coal that is diverted to the East after the lake trade ends, about Dec. 1.

Lake Trade—The mobilization committee in charge of the Great Lakes ship pool this season has announced that in order to expedite the handling of coal cargoes at the head of the lakes all vessels, when possible, will be shifted from the so-called "slow" docks—slow in unloading—to the so-called "fast" docks. This has resulted in considerable dissatisfaction. Some operators assert that the operators who benefit from this step are the ones who made no especial effort early in the season to get their coal up; the efforts of those who dug in will not bring them any special reward, they complain. On the other hand, members of the mobilization committee point out the situation to be as follows: The operators who will be aided by this order are those working gas-coal properties. They had planned last spring, as usual, to send their coal up the lakes, and made no effort to contract for free coal. But the Federal Fuel Administration stepped in and ordered that no gas coal was to be sent to the Northwest. The result was that by the time this ruling was announced other operators had "sewed" up all of the free coal and none was left for the gas-coal men. Hence the need for assistance for them at present. This much, however, is held in common by all lake coal shippers—the iron ore interests more and more are seeking to govern the movement of coal, which is something the coal men feel should be reserved for themselves.

DETROIT

Low temperatures emphasize deficiency of domestic fuel supply. Steam plants find it difficult to replace coal diverted from Ohio, Kentucky and West Virginia. Lake movement is heavy.

Bituminous—Steam-coal users deprived of supply from mines in the West Virginia, Kentucky and Ohio districts by the recent orders of the Federal Fuel Administration in modification of zone restrictions, are experiencing some difficulty in obtaining substitute fuel. Complaint is made that the mines in Illinois are not filling orders promptly and seem unable to handle the increased business allotted them, in a manner satisfactory to the buyers. The coal sent from the Illinois and Indiana mines is pronounced inferior to that which the Detroit industrial plants heretofore have been using, though with the freight charge added its cost is practically the same as for the more desirable southern coal. A number of the large manufacturing plants, working on Government orders, are reported to be supplying their current requirements by drawing on reserve stocks that were intended to tide them over winter emergencies or interruptions of supply.

Jobbers assert that the modified zone regulation is not proving as helpful in adding to stocks of domestic consumers as was expected. The prepared sizes, they say, are being rushed to the lakes for shipment over the routes favored by priority order, rather than over the all-rail route to Detroit. Business of the jobbers is cut deeply by the changed zone regulation, as the only market left them for southern coal in the lower peninsula of Michigan comprises railroads, byproduct and gas plants, and domestic trade. With stock suitable for domestic use arriving in only moderate amount, and buying by railroads, gas works and byproduct plants not large in volume, the jobbers are getting slim picking.

Anthracite—Cold rains and low temperature have brought an insistent demand from domestic consumers seeking anthracite. The deficient supply and restrictions giving priority to base-burner owners on delivery of chestnut and stove sizes combine in balking efforts of many of the would-be buyers. Homes dependent on hot air furnaces are required to have put in an amount of bituminous equal to one-half their winter fuel needs before they can receive any anthracite.

COLUMBUS

The steam trade is not as overstocked as a week ago because of further modifications of the embargo against shipping screenings into Michigan. There is a continued good demand for domestic and lake tonnage.

The steam situation has been relieved to a certain extent because of modifications to the embargo against shipping small sizes into Michigan, and there is not so large a stock on the local market. In addition certain steam plants have been stocking up steadily, and many have a supply of from three to four months. Railroads are still taking a large tonnage as the freight movement continues extra heavy. Schools and hospitals have been supplied, and the same is true of public institutions. On the whole, the steam trade is running along in a more normal channel.

The domestic trade is one of the strongest points in the market. There is a considerable tonnage moving from mines into yards, partly to take care of current business and partly be used in stocking up for the future. Retail stocks are gradually getting larger. One of the worst features is the fact that lump is rather scarce, while there is an ample supply of mine-run. Retailers are fairly busy making deliveries. It is estimated that about 75 per cent. of domestic coal in this section has been stocked by the consumers.

The lake trade is also active and considerable attention is now being devoted to that branch of the industry. The vessel movement is generally efficient and little delay is experienced either in loading or unloading. The ore movement is also good and consequently the coal trade is stimulated. The movement off the docks to interior points in the Northwest is rapid and no congestion is reported.

CINCINNATI

Volume of business is high, with good movement from the mines and good local supplies on hand. Question of future industrial consumption is the chief cause for worry.

The excellent state of the local situation, both for domestic and individual consumers, may be gathered from the fact that the former, as a rule, have their winter's supply, or at least half of it, already in their basements, while the latter, wherever storage is available, usually have several months' supply stored. These is at least one large coal concern, with operating connections, which has been advertising for orders from industrial consumers, assuring them that it has ample coal to take care of all orders. The movement of coal from eastern Kentucky and West Virginia continues at a heavy rate, and with shipments by river being aided regularly by artificial rises brought about by means of the Government dams, Cincinnati is assured of a regular supply of coal. Whether this will be sufficient, with the constantly increasing consumption both locally and to the North for heating purposes, as the season advances, is another question. The peak of industrial consumption, of course, is also ahead, and as the average industrial consumer, unfortunately, cannot possibly store enough coal to last for more than a week or so, maintenance of the present movement, and its increase, if possible, are just as necessary as elsewhere. However, the general feeling among the trade, and among the authorities in charge of the fuel situation, is distinctly optimistic, and while this is based largely on the extent to which the public at large, including domestic consumers principally, has been induced to store its winter supply of coal, it also has regard to the prospects for taking care of the industrial situation in good shape.

LOUISVILLE

Local conditions reflect a general shortage of lump coal for domestic use, with mine-run and screenings in plentiful supply, and the market a little draggy on such coal. Car supply much better at mines, labor supply slightly easier and production on upgrade.

Conditions in the Louisville market are about the same as they were last week, with the exception that there is a still greater surplus of mine-run and screenings, which are not selling readily. Industrial plants appear to be well stocked and under regulations of the Fuel Administration are not buying freely. Jobbers and producers are meeting with some little trouble just now in disposing of steam grades, although there is an active demand for domestic or lump coal for stocking purposes. Most of the stocking at this time is in small lots, of one to four tons, except on eastern Kentucky coal, where many consumers have been waiting for deliveries.

Yards are laying up practically no surplus of lump coal, being unable to secure enough for requirements. A little mine-run is being stocked by some companies for emergencies, as they want to secure surplus stocks of some sort, and can not secure lump. Industrial consumption is taking more mine-run at this time than screenings, due to the fact that it stocks better, and is even easier to obtain than screenings as many producers are not screening at this time.

BIRMINGHAM

No marked change in Birmingham market. Steam demand easy in tone but of satisfactory volume, while domestic trade is strong and the supply short. Production slightly lower than the previous week. Car supply fairly good.

Reports in trade circles indicate a good, steady demand for steam coal, but the situation is devoid of any tenseness. The rail lines are taking coal on about the same basis as observed for several weeks past; the supply with some roads, however is said to be very short and fuel agents have been in the market lately to secure additional tonnage. There is practically no free coal available at present.

Domestic dealers still have many unfilled orders on file and new ones are being received about as rapidly as deliveries are made on old ones. The production of lump coal is short of requirements and a great deal of mine-run coal is being stocked for domestic use.

The output of coal in this district for the week ended Sept. 21 was 382,000 net tons, or about 50,000 tons short of the maximum weekly production record of two months ago. The loss is attributable to irregular work and shortage of labor, the car supply having been fairly good and little, if any, interruption was caused by lack of equipment. The production committees of the fuel administration are now fully organized and at work, and it is to be hoped they will be successful in bettering the production materially.

Coke

CONNELLSVILLE

Coke quality improving. Byproduct supplies maintained with difficulty. Heavier Connellsville coal shipments.

Blast furnaces in increasing number are reporting a visible improvement in the quality of coke received, but as a rule those who have had cause for complaint feel that there is still much more to be done. Pig-iron production has been at an increasing rate, but as output always increases at this season of the year, on account of decreased atmospheric humidity, it is impossible to trace directly the influence of improvement in coke quality upon blast furnace operations. As has been the case for some time past, there is only occasional shortage of coke, in point of actual tonnage. Furnaces would like to have more coke, however, as it is desirable to accumulate a reserve against winter conditions. Very little coke has been in stock at any furnace.

The Fuel Administration continues to watch closely the amount of coke offered as foundry grade, and requires that this be kept down to the actual needs of foundries engaged in war work, all other coke to be offered as furnace no matter if it has been in the oven 72 hours. These regulations have been helping the furnace coke supply for some time past.

The Fuel Administration has thus far had little success in finding byproduct coal to ship to byproduct ovens that have been receiving Connellsville coal, for the purpose of allowing the Connellsville coal to stay in the region and be coked in beehive ovens. The ruling made some time ago that beehive ovens must not be blown out promptly became practically a dead letter as it was impossible to observe it except at the expense of depriving byproduct ovens of coal, and a full supply to them is essential on account of the byproducts. There

is no prospect of any early improvement continued nearly if not quite to the end in this respect, as lake shipments are to be of the navigation season. Afterward there may be coal that can be diverted to by-product ovens to relieve Connellsville coal shipments.

The market is quiet and remains quotable at the set limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over 3-in., $7.30; clean screenings from old dumps, over ½-in., $5.50, all per net ton at ovens. Some minor screening operations have dropped out since the price limit was reduced to $5.50, apparently because too much labor was involved in the operation, but there is still considerable marketing of this material, for household purposes.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Sept. 28 at 335,195 tons, a decrease of 4280 tons, and coal shipments at 245,136 tons, an increase of 22,733 tons.

GENERAL REVIEW

Mines producing more coal than territory can absorb. Steam market soft, as all large manufacturers have plenty of storage coal in reserve.

The mines in the Middle West are continuing to produce record tonnages, as the car supply is good, the labor situation favorable, and there are no serious storms to tie up traffic or cripple individual operations.

The coal market continues soft and, as has been the case for the whole month of September, the mines have produced more coal than the territory can easily absorb. The Fuel Administration has taken steps to alleviate this state of affairs, and it is now definitely announced that Illinois and Indiana coals are to continue to move into the lower peninsula of Michigan. Michigan, by the way, is no longer suffering for coal, and both Indiana and Illinois sales agents are having increasing difficulties in placing orders in that state.

A second step, and one which will relieve the situation to a certain extent, has been recently promulgated. Railroads doing business in Indiana, who have hitherto been purchasing their fuel in either Ohio or Pennsylvania, have been ordered to buy their coal from Indiana operators. This has proved an extremely wise measure, as it has tended to relieve some pressure from the East, where we understand there is an increasingly serious shortage, and at the same time has helped conditions in the Middle West, where the market is weak and needs strengthening.

Some of the largest producers in this territory are freely predicting a soft market on steam coal to continue throughout the winter season. They base their predictions on the fact that practically all the big manufacturers have in stock at the present time enough coal to last them from two to four months.

CHICAGO

Steam coals offered freely. Railroad purchases large. Screenings are selling at substantial reductions.

Conditions in the Chicago coal market differ little from the general situation in the Middle West territory. Nearly all steam coals are offered freely, and only a few of the better known and higher grade products are being sold on a basis of Government price. The mine-run situation is improved slightly, owing to large purchases on the part of the railroads, but screening sizes are to be had at substantial reductions.

The domestic market is a little better off, as the recent cold weather, combined with the Spanish influenza scare, has caused the domestic user to burn some coal to keep his place warm, and whenever possible he has bought additional fuel, rather than start in on the coal he has reserved for the winter.

MILWAUKEE

Fuel administration's schedule of prices for anthracite questioned by dealers. Threats of refunds if overcharges are made. Measures of conservation.

Before leaving for Washington, where he will endeavor to have Wisconsin's allotment of coal increased, State Fuel Administrator caused the following schedule of prices for anthracite to be promulgated: "Under date of June 24, the United States fuel administration established the prices of anthracite coal f.o.b. cars at the docks on the coal which left the mines prior to June 25, as follows: Egg, $8.35; stove, $8.57; nut, $8.66; pea, $ .19. On anthracite coal leaving the mines on and after June 25 there is an addition of 40c. per ton to the above prices f.o.b. cars at the docks, made necessary by the advance in freight rates from the mines to Lake Erie ports. During the summer there was a voluntary reduction of 30c. per ton on anthracite coal as an inducement for people to order and take in their coal early, if it was available. This voluntary reduction expired Sept. 1, and after that date 30c. per ton was added to the price. At the present time the prices f.o.b. cars at docks are: egg, $9.05; stove, $9.27; nut, $9.36; pea, $7.89. To these prices should be added $2.25 per gross ton which covers all expense of retailing and delivering such coal to the consumers' curb, the prices for curb delivery being as follows: Egg, $11.30; stove, $11.52; nut, $11.61; pea, $10.14. These are the maximum prices prevailing in the city of Milwaukee on coal handled by all the large dock companies." The consumer pays an additional 70c. per ton for carrying the coal from curb to bin. The fuel administrator threatens to impose refunds wherever overcharge from the above rates are discovered.

Retailers are somewhat puzzled over the latest order, as it is at variance with the prices they have been permitted to charge following the conditions noted in the fuel commissioners' detail, and there is a disposition to await Mr. Fitzgerald's return before making any change.

Coal receipts at Milwaukee by lake during the month of September foot up 96,451 tons of anthracite and 631,775 tons of bituminous, making the receipts during the season of navigation thus far 461,428 tons of the former and 2,778,187 tons of the latter. There are about 10 weeks of lake navigation still ahead.

ST. LOUIS

A continued easy market, with a surplus of all coal, excepting Carterville. Steam and domestic demand light. Car supply good and transportation improved.

The St. Louis market is an easy one. It is hard to find a place for some sizes of coal from the Standard and Mt. Olive fields. Car supply has shown improvement during the past week and transportation continues better.

In view of the fact that between 75 per cent. and 85 per cent. of the domestic tonnage usually stored by December has now been delivered, the market will continue easy for domestic coal from this time on, with the exception of Carterville. There is still a shortage on that locally, not only for domestic but also for steam. The domestic demand from the country has eased up in the past week and the same pertains to steam sizes.

A good railroad tonnage moves in from all the fields, and this is the only thing that is saving the southern Illinois market at the present time. In the Carterville field cars are not so plentiful as the operators would like, but the service rendered is good in comparison with the past. Some mines are catching up on orders. A large tonnage continues to go on Government requisitions, and the railroads are still pulling heavily. Labor and other conditions are about normal under existing circumstances. In the Duquoin field there is little change. The Mt. Olive district still produces more coal than it can find a ready market for. Car supply here is good, and in a general way this field is a satisfactory one to the operator. Labor is good and cars plentiful. The Standard field presents the same old problem of overproduction. The distribution of cars has shown some improvement here, and transportation facilities have also developed better in the last few weeks. There is, however, unbilled coal in this field nearly every night on all sizes. One of the problems in this field that has not been regulated is the taking over by the Government of certain short-line roads that openly discriminate in the distribution of cars, leaving some mines idle and working other mines full. No eastern fuels are moving into this market and very little from Arkansas.

The prevailing market per net ton f.o.b. mines is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump..	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg..	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut.	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1.....	3.05@3.20	3.05@3.20	.....
No. 2.....	3.05@3.20	3.05@3.20	.....

Special preparation on Carterville is 10 cents extra.
Williamson & Franklin Co. rate is $1.10.
Other fields 95 cents.

KANSAS CITY

Retail prices increased after investigation of costs of doing business. Labor and miscellaneous items show increased cost.

The state and local fuel administrations gave to Kansas City, Mo., coal dealers, effective Oct. 1, an increase in retail prices of about 30c. a ton on bituminous and 45c. on semi-anthracite coal. Further increase will be established Jan. 1, 1919, of 25c. on bituminous and 10c. on semi-anthracite. The advances allowed on anthracite range from 5 to 80 cents.

The advance was the direct result of a report made by Gregg & Co., accountants of St. Louis, who made an investigation of local costs of doing business, at the instance of the retail dealers of Kansas City. The fuel administration had indicated that it would try to fix such prices as would allow a net profit of about 35c. per ton. The report of Gregg & Co. showed that dealers were not receiving this profit. The report made plain the fact that no absolute guide to a proper level of prices could be established now, since prices paid by coal dealers for various costs of operation were changing rapidly. For instance, dealers raised their teamsters from 30 to 35c. an hour recently; truck drivers are asking an increase from 35 to 40c. Unloading wages were formerly 5 to 15c.; now the range is 15 to 30c. Hay cost $31 a ton a year ago, now it is $40—with prospect of early advance. In view of the advancing costs of doing business, the fuel administration granted the increase in retail coal prices, though not as large an increase as the dealers hoped for, or as the report of the accountants indicated would be just.

The state fuel administrator, Wallace Crossley, in an interview announcing the advance to the public, remarked that the dealers had been operating on too narrow a margin.

SEATTLE

Secretary of Fuel Administration says domestic fuel situation is worse in Northwest than any other section of the country and predicts closed industries as war necessity.

The domestic coal situation is worse in the Northwest than any other place in the United States, according to David Whitcomb, executive secretary of the Fuel Administration of Washington, D. C., who is in Seattle while arranging for the departure of his family for Washington. Whitcomb was formerly fuel administrator for this state. Shortage of labor and the small demand for industrial coal in the Northwest are the reasons advanced for the domestic coal shortage, according to Whitcomb. Domestic coal for home consumption is usually the large lump coal. The fine coal has a small market in the Northwest, and it is impossible to mine the larger lump coal when there is no market for the fine coal which is mined at the same time. Some industrial curtailment of fuel will be made in this section this winter, he reports, as well as in certain parts of the Middle West and East.

The problem of the administration at this time, he states, will be to draw the line between essential and non-essential industrial plants and close down the latter as a war time necessity next year. He declares that people who complain of the scarcity and price of coal do not realize that the United States is the only country which has increased its coal tonnage since entering the world war. The domestic consumers of the Northwest will have to use pea coal or do without, is the opinion of coal operators of this section, who state that this class of fuel is in abundance.

General Statistics

NORFOLK & WESTERN

A statement of coal tonnage from mines on the Norfolk & Western R.R. and from other railroads, for the month of August, 1918, is as follows:

From:	Net Tons
Pocahontas field	1,470,411
Tug River field	316,574
Thacker field	295,868
Kenova field	125,057
Clinch Valley field	174,015
Other Northern and Western fields	16,594
Total Northern and Western fields	2,398,492
Williamson & Pond Creek R.R.	214,843
Tug River & Kentucky R.R.	66,697
All other railroads	96,663
Grand total	2,776,695

COAL AGE

Volume 14 New York, October 17, 1918 Number 16

The Days of Reconstruction

By Floyd W. Parsons

NOTHING can change the fact that war is a school where the tuition costs more than the learning is worth. However, the present conflict on our part was unavoidable, and we have been compelled to meet the situation with all the force we could muster.

When peace comes this Nation, like all the other great countries, will have to start paying off a debt that is so colossal it is beyond the average understanding. Victory, and a dictated peace, will mean the end of the horrors of killing men, but it will also mean the commencement of our struggle to pay the bill for our battles for liberty.

The money expended by the seven leading belligerents for purely war purposes up to the present time amounts to more than $141,000,000,000. The combined average war cost is now $4,500,000 each hour of the day. The total net war debt of the principal nations engaged in fighting is $132,000,000,000.

Let us not deceive ourselves concerning the years following the war. There will be industrial activity in certain lines, for we must gradually reclaim wasted areas and readjust our lives. But the wholesale destruction of life and property is not the precursor of prosperity. The task of healing the wounds that civilization has received will necessitate our enduring further sacrifices and continuing the maximum observance of our newly created conservation and efficiency measures. In other words, our future success will depend largely on our ability to avoid a relapse into the wasteful and careless industrial habits of our pre-war days.

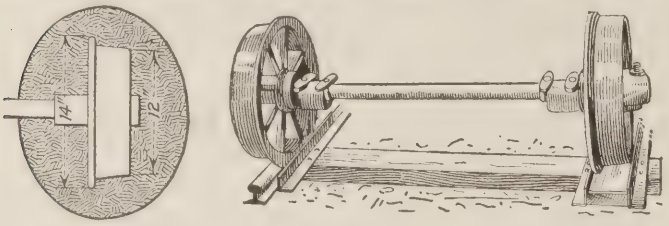
Here and there among all our trials and sorrows are a few bright spots. Chief of such benefits is our better knowledge of standardization. The need for greater production at a time of labor shortage has forced our leaders to seek shortcuts, adopt new methods and substitute machines for men. Economy and efficiency are the watchwords of the day.

We have learned that standardization is something more than the pet hobby of efficiency experts. The doctor cannot make a correct physical diagnosis unless he compares his readings of the individual with the standard or normal respiration, heart beat and body temperature. Measurement is the soul of standardization; through it we determine the degree of quality and the rate of performance.

No longer do we believe that standardization means fixity of progress. Like the bark of a tree, it may bound progress but must not limit growth. Inflexible standards retard development. True standardization is the consensus of the best that an industry affords and always keeps step with the advances of that industry. At least we have come to know that the elimination of chance in our national effort has ushered in a new and better era.

What I am trying to get across to the reader is a broad general thought that should be discussed and developed in *Coal Age*. We have as an important principle of standardization the "interchangeability of parts," and there are other subjects equally vital to the big problem.

I want to ask coal-mining men in every field who are desirous that our industry shall not lose the ground gained through our present emergency to write us a few thoughts on this important question. We may enter the after-the-war period of reconstruction sooner than we anticipate, and no problem is of greater importance than the national standardization of coal mining.



Do your part to help develop plans that are both practical and constructive, and let us hear from you today.

IDEAS AND SUGGESTIONS

Suggestion for a Sharp Curve

BY MATTHEW STAFFORD
Chase River P. O., Vancouver Island, B. C.

Sometimes a mine manager or foreman is crippled for lack of room for a proper curve either at the top or bottom of a shaft. I think as a general rule this applies to pit heads and to turning the cars, either when full from the cage or when empty toward it. Especially is this the case where the pit head has had to be changed in certain respects in order to meet a larger

TAKING A CAR AROUND A SHARP CURVE

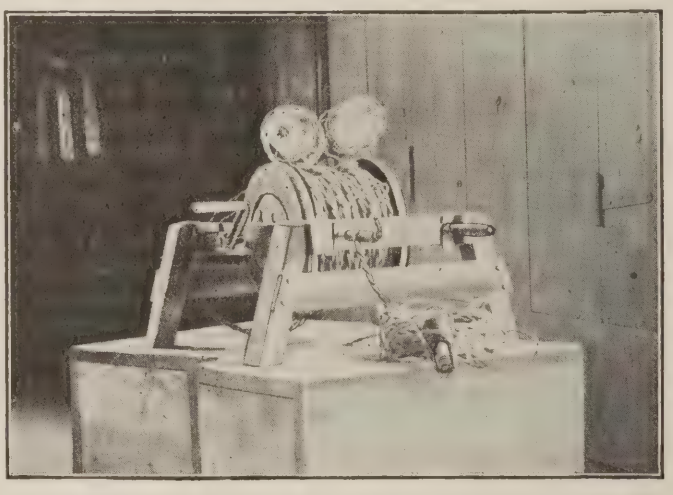
output. The following suggestion is practical and will help to solve problems incident to the foregoing conditions.

We will assume that the car wheels are 12 in. in diameter and the flange say 1 in. high. This will make a 14 in. diameter measured over the flange. When the car comes onto the curve the outside wheel runs on the rim or flange, which is of greater diameter than the tread. A flat sheet of iron is laid upon a curved wooden rail on either side of which, as well as on the inside of the inner rail, an angle iron is placed. The circumference of the flange on the outer wheel is of course greater than that of the tread on the inner wheel. The outer wheel gains at each revolution approximately 6.28 in. on the inner wheel. This, together with the easy skidding of the flange on the sheet iron, enables the car to be taken readily around a sharp curve.

Straightening Bent Rails

BY W. H. BUTLER.
Christopher, Ill.

The straightening of curved rails is sometimes a difficult operation at a coal mine. I have been able, however, in many cases to use a method that requires only a short time to manipulate and accomplishes results that answer all purposes. The tread of practically all locomotive wheels is wider than the ball of the rail upon which it runs. Consequently, to straighten a crooked rail all that is necessary is to place it beside a straight track rail, properly support it with its convex side up and run a heavy locomotive over it once or twice. Of course, at least one end must be so supported that it is free to move endwise, as the span of the rail will be greater when straight than when crooked.



Should the end portions of the rail still be curved the extreme ends may be supported by cap pieces or otherwise and the locomotive again passed over the rail. This method, while it may perhaps seem crude, is nevertheless effective. Furthermore, under ordinary circumstances it is several times as rapid as straightening a bent rail with a jack or rail bender.

Portable Lighting Set

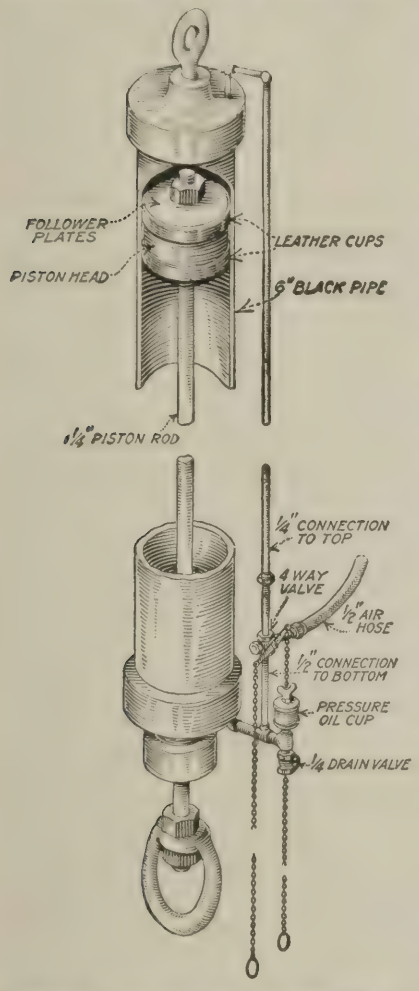
BY FRANK HUSKINSON
Trinidad, Colo.

Many jobs around the mine, such as repairing machinery or putting timbers in place, can be handled more conveniently with the aid of electric lights than by the employment of other means of illumination. This is particularly true if the repair job is located in the aircourse or some other part of the mine where the movement of air is strong.

After experiencing all the inconveniences incident to the use of open lights and electric cap lamps in repairing machinery underground, I devised the portable electric lighting set shown in the accompanying illustration. This set consists of a spool or reel of suitable size on each end of which is fastened a circular brass plate to which the wires wound upon the spool are connected through the spool axle. The spool is hung within a suitable frame and provided with a winding crank, as shown. A piece of spring brass is attached to each side of the frame, making contact with the circular brass plates upon the ends of the spool. These brass brushes are connected to the two terminal posts upon the frame.

LIGHTING SET THAT CAN BE CARRIED EASILY

A piece of lamp cord is fitted with plug terminals on one end to fit into the two terminal posts. On the other end this cord is fitted with an attachment plug to screw into a standard lamp socket. There are also provided two hook terminals to be attached to trolley wire or feeder cable and rail.



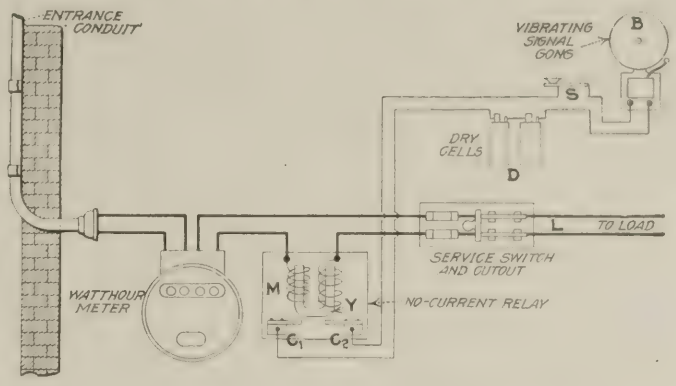
The amount of lamp cord on the reel or spool may vary with local requirements. I have found that from 400 to 500 ft. is ample for most purposes. A few feet

or the entire amount may be unreeled as occasion demands and as many lamps used as are needed.

This device has demonstrated its utility on numerous occasions. Its use is not confined to the mines alone, as it is a valuable contrivance to have in the shops. It is simple, inexpensive and easily constructed. It may be built by almost anyone and sufficient use for it exists to warrant almost every mine possessing one.

Homemade Air Hoist

The accompanying illustration shows an air hoist that can be made at almost any mine shop, where it may be employed to good advantage. Such a hoist may be used either for lifting heavy work into or away from the lathes or other machines, or for overturning cars or similar work. It has the great advantage over a chain block of being much more rapid in action; furthermore, it is far less liable to be taken away from the shop for heavy lifting elsewhere. The drawing is almost self-explanatory. The hoist cylinder, or barrel, is made of a piece of ordinary 6-in. pipe. The piston is constructed of three disks and two cup leathers faced in opposite directions, the whole being held firmly together between a collar on the piston rod and a nut on the end. The admission and release of air is controlled by a suitable cock operated from the floor by means of suitable hand rods. The length of the hoist cylinder and travel of the piston may be made to suit local requirements. One hoist of this kind that has been in successful operation for some time and has proved itself a great time saver is made with a lift of 4 ft. 6 in.



THIS AIR HOIST CAN BE MADE AT ALMOST ANY MINE SHOP

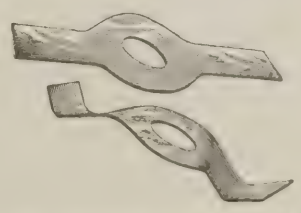
In operation such a hoist as this may be mounted upon a jib crane or a track suspended either permanently from the roof trusses of the building or from a frame in the repair yard, or it may be hung from a chain or eyebolt if horizontal movement is not necessary. Such a device as this may be constructed at small expense, and in many instances, at least, will not only be found highly convenient, but also prove itself a time saver of appreciable value.

Audible Signal to Indicate Discontinuance of Load

The accompanying illustration shows how a signal bell was connected so that it will ring when a group of motors in a distant building is stopped. The relay *M* was made and connected to the supply wires to the load. When the load is taking current through the line *L* the magnet coils of *M* have current in them and pull

METHOD OF CONNECTING AUDIBLE SIGNAL

up the U-shaped yoke *Y*. But when the load is discontinued, *Y* drops down and makes contact across C_1 and C_2. This closes the electric-bell circuit and causes *B* to ring, and it will continue to ring until the switch *S* is opened.



The magnet coils *M* do not require many turns, as all they have to do is to hold up the yoke *Y*. It is not, in most cases, necessary that they be strong enough to pull up *Y*, because it can be raised by hand. The wire used for the magnet coils *M* must, however, be large enough to carry the full load current in the circuit.

Positive Grip for Oil Cans

By J. A. Lucas
Ozone Park, N. Y.

It is quite unpleasant to have an oil can slip out of your hand, when standing on top of a ladder. To avoid this, I applied the little device shown in the accompanying illustrations. It is cut out and formed as shown in the pen and ink sketch, and is used on the oil can by tightening it between the oil container and the spout. This device will also prevent the oil can from tilting.

LITTLE DEVICE MAKES AN EFFICIENT GRIP FOR AN OIL CAN

Increasing Coal Mine Efficiency—I

By CHARLES E. STUART
United States Fuel Administration, Washington, D. C.

SYNOPSIS — *The first of a series of articles upon the subject of mine efficiency. Many operators and "practical" coal men do not yet realize that the power generation and distribution system of the fair-sized mine offers problems more complicated and intricate than exist in the ordinary town of 25,000 inhabitants.*

Introduction

IN ANY present-day consideration of coal-mine operation having in view increased coal production and operating efficiency, certain war factors must constantly be borne in mind. No study of the subject can be properly made without due allowance for existing war conditions, such as decreasing availability of required machinery; increased delay in obtaining factory repairs or repair parts; increasing load on central stations already frequently overtaxed; and decreasing man power incident to the requirements of the army and as a result of the tempting offers of other classes of war industry.

There is urgent demand for every pound of steel that can be produced. This is needed for the construction of ships, and for the manufacture of shells and other war material. Furthermore, the man with the skill to turn the axle of a mine locomotive can likewise turn an urgently needed shell; in a word, we are short of both skilled labor and raw material for imperative war requirements. Nevertheless, and in spite of these facts as well as because of them, we must increase the production of coal.

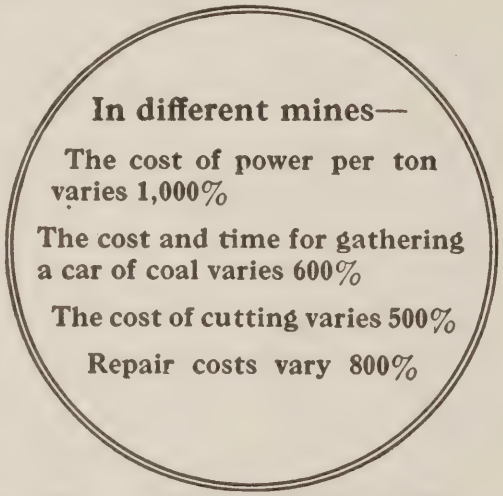

FIG. 1. COMPARATIVE ANALYSES SUMMARIZED

This series of articles will not be technical. An operator who regards himself as qualified to purchase a fan motor need not hesitate to study it because of the introduction of curves and other descriptive technical data. The operator capable of specifying and purchasing such a motor will recognize the information as elementary. He will also agree that the facts presented are logical, and they may perhaps recall considerations to which he has at odd times given some casual thought, or difficulties which he has definitely attempted to solve.

The fact that electrical and mechanical engineering skill has become as important a factor in the efficient management of mining properties as civil engineering ability, is today appreciated only by some of the larger and better organized operating companies.

Fig. 1 summarizes the results of a number of comparative analyses. The physical handicaps of the properties have a bearing on the extremes indicated, but these considerations have, relatively speaking, only a small influence. The following report of power consumed and tonnage output is illustrative:

15-Min. Demand, Kw.	Consumption, Kw.-Hr.	Tonnage Output	Kw.-Hr. per Ton
Operation No. 1			
June 518	90,700	35,000	2.7
July 547	101,600	36,400	2.8
Operation No. 2			
June 374	112,100	60,599	1.9
July 412	123,400	60,946	2.0

Mine No. 1 consumes 40 per cent. more power and has 30 per cent. higher power demand. There is some difference in the operating conditions, but nothing that would cause such a wide variation of output to demand as that cited above.

The average town of 25,000 population contains a pumping plant, which takes its water from a single source by a single lift. The municipality contains a well-regulated trolley system. There may be several factories containing more or less complicated systems of electrical drive, and in each and every instance there is maintained a well-organized engineering force headed by a capable electrical or mechanical engineer, or an engineer manager.

The mine with a capacity of 1000 tons a day contains a generating or converting plant, the load upon which corresponds both in diversity and complexity to the combined requirements enumerated in the case of the town of 25,000. The pumping system of the mine is invariably more complicated. If the miner is not properly served by the haulage system, he becomes idle through a greater or less period of time.

The subject of mine ventilation considered in relation to power demand and consumption is in itself an art to which the town offers no parallel. Extremely few factories, for instance, contain motor drives whose needs in the way of skilled attention compare with the requirements of a tipple designed to prepare coal properly for coking and for the market. The lighting requirements of the average mine camp are identical to those of the small town, provided the miners' homes are to receive reasonably good service and the mine itself is to be properly lighted.

In many instances a mine operator does not appreciate the complexity or possible efficiency of his expensive equipment, and is entirely satisfied with an electrician who can keep things going. Frequently, such electricians are capable of serious efficiency work and would gladly undertake it if requested or encouraged to do so and furnished with the necessary assistance. Such an attitude on the mine operator's part is distinctly shortsighted and results in loss of greatly needed coal production, both to the mining company and to the country.

There is another phase of equal importance to the operator from a personal viewpoint—namely, the relationship of investigation and improvement recommended herein to cost and profit. Every recommendation made, if carried out, will save money; or, conversely, will make money for the mine operator. It should be remembered also that no suggestion is made in this series of articles whose value has not been fully demonstrated in practice. These suggestions are not impractical and will only

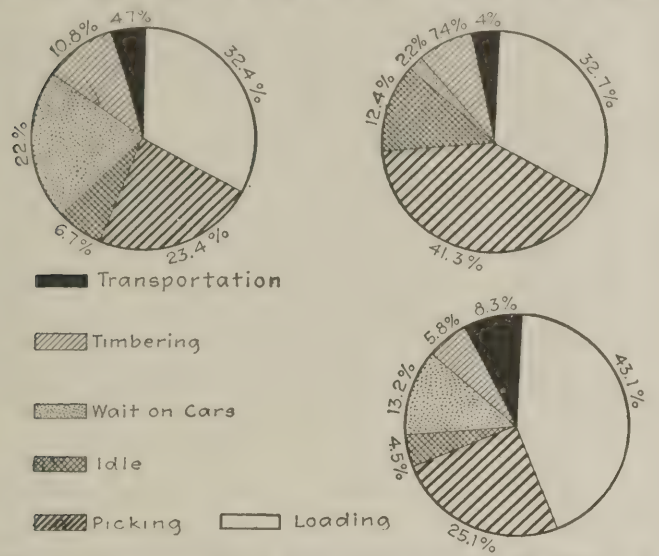

FIG. 2. COMPARATIVE PERFORMANCE OF MINERS IN THREE MINES

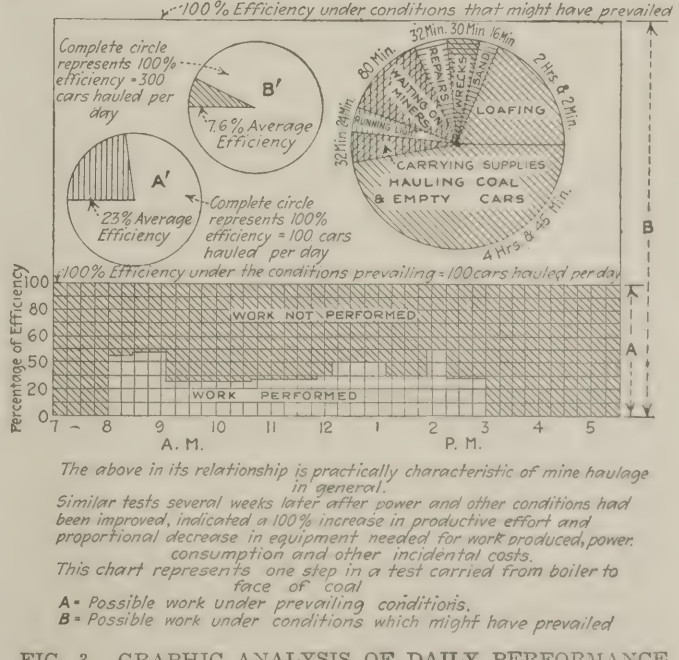
appear so to the superintendent or owner who is unable to grasp their significance, or who is unwilling to give the small amount of time necessary to digest the recommendations here made and put forth the subsequent effort that may be requisite in order to carry them out.

To repeat, I am endeavoring to bring to bear a few simple analyses to show that the mine operator with the help at hand is in position to go a great deal farther today than he is now going to meet the demand for conservation in its broad economic sense.

None of the considerations and conditions enumerated in the foregoing should be overlooked in considering the following factors in mine operation, which will be covered in this series of articles: (I) A comparative analysis of a miner's working day. (II) An analysis of the performance of mine locomotives. (III) An analysis of the performance of cutting machines. (IV) The power demand and consumption of mine fans. (V) An analysis of power demand and consumption of mines in relationship to capacity and production. (VI) An analysis of mine power conditions in relationship to production. (VII) A consideration of track conditions in relationship to production. (VIII) The condition of the generating plant. (IX) The relative output of electrified vs. unelectrified mines. (X) Considerations in the case of a shortage of central station capacity. (XI) A coal mine efficiently electrified using purchased power.

I—Comparative Analysis of a Miner's Working Day

Fig. 2 shows the comparative performance of miners in three different mines, two of which are electrified. To arrive at these summaries, a careful analysis was made not only of the actual employment of time by the miner, but also in order to locate and isolate all elements tending to delay him. It is the rule to blame the miner for a small day's production, but we rarely hear of the superintendent or foreman taking unto himself criticism for failure to keep the miner properly supplied with cars.



The showing in Fig. 2 is by no means a poor one, or below the average. On the contrary, the group of mines where the observations were made are supposed to be among the most efficiently operated in the country; and

TABLE I. AVERAGE PERFORMANCE OF EQUIPMENT AND MINERS

Hoist:	Minutes	Per Cent.	Gatherers:	Minutes	Per Cent.
Hoisting cars	231	51.2	Hauling	286	49.7
Hoisting supplies	125	22.3	Running light	81	14.1
Waiting for loads	123	22.0	Waiting on loads	89	15.5
Wrecks	60	10.8	Waiting on empties	75	13.0
Idle	21	3.7	Waiting on drivers	...	...
			Wrecks	28	4.9
Total	560	100.0	Idle	16	2.8
Haulage Motors:			Total	575	100.0
Hauling	284	49.3	Miners—Average of 6 Men		
Running light	39	6.8	Loading	217	41.9
Waiting on loads	73	12.6	Picking	141	27.2
Waiting on empties	10	2.0	Idle	53	10.2
Waiting on motors	...	...	Waiting on cars	60	11.5
Wrecks	164	28.2	Timbering	25	4.8
Supplies	6	1.1	Transportation	23	4.4
Total	576	100.0	Total	519	100.0

furthermore, their output of coal per miner is a record output. Table I gives several average performances of equipment and miners.

Fig. 4 is a graphic analysis of daily performance showing how the summary in Fig. 2 and the comparative analysis in the table are obtained. We are particularly concerned with those elements of delay which bring about the "wait on cars." Such delays may be classified under the heads of "avoidable" and "unavoidable." Unavoidable delays are those such as occur in any system of transportation. For example, there will be delays incident to transfer of cars from one locomo-

The above in its relationship is practically characteristic of mine haulage in general.
Similar tests several weeks later after power and other conditions had been improved, indicated a 100% increase in productive effort and proportional decrease in equipment needed for work produced, power consumption and other incidental costs.
This chart represents one step in a test carried from boiler to face of coal
A = Possible work under prevailing conditions.
B = Possible work under conditions which might have prevailed

FIG. 3. GRAPHIC ANALYSIS OF DAILY PERFORMANCE OF LOCOMOTIVES

tive to another. Wrecks may occasionally be classified as unavoidable.

In a general way, avoidable delays as here considered are such as are occasioned by a section of the haulage system being congested or inadequate for the work. The chief causes which are responsible for the element of

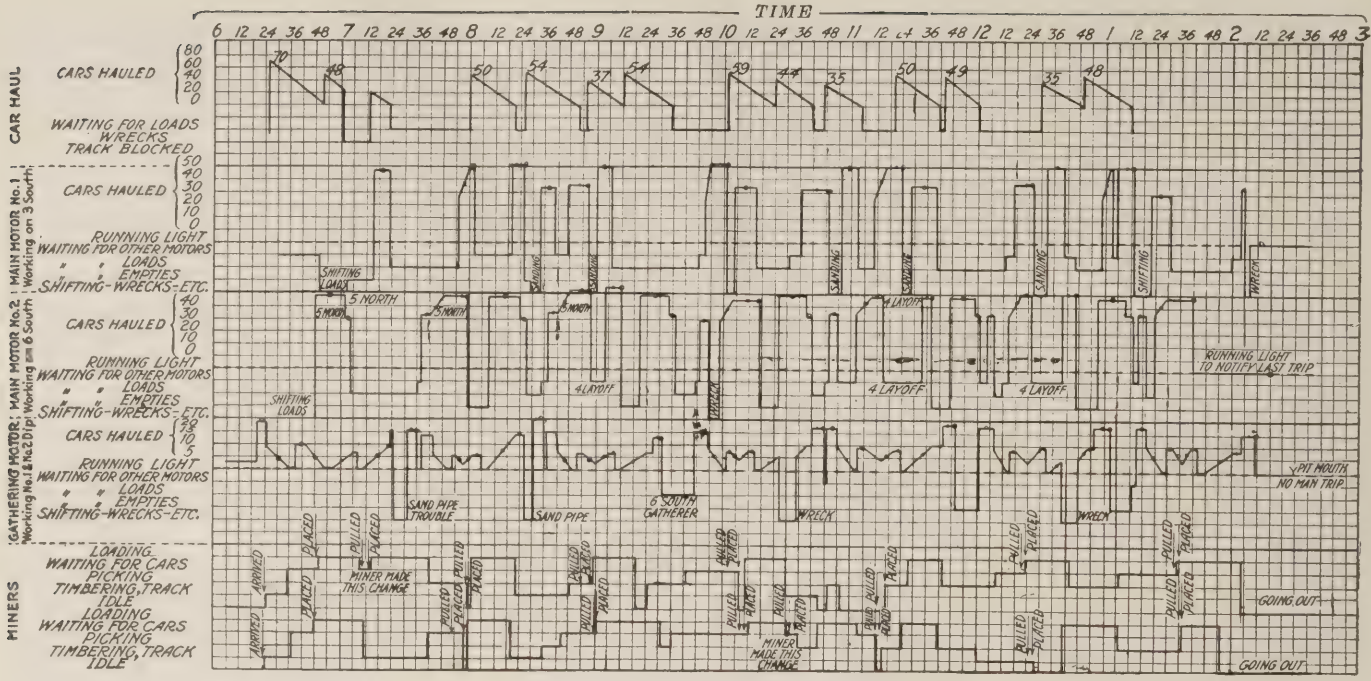


FIG. 4. COMPOSITE RECORD OF PERFORMANCE OF LOCOMOTIVES AND MINERS

time loss shown in Fig. 2, and which may be classified as avoidable, are as follows: (1) Handling supplies; (2) sanding motors at other points than where stops are regularly made; (3) insufficient capacity of loaded and empty partings; (4) poor signal system; (5) insufficient number of cars; (6) wrecks; (7) locomotive trouble due to lack of inspection; (8) delay due to failure to place car ready for miner on his arrival; (9) indifference of motormen; (10) bad management.

II—Analysis of Mine Locomotive Performance

The converse of the analysis of a miner's working time is indicated in Fig. 3. Here we have the composite record of the average performance of a number of gathering locomotives as taken in different mines. Practically speaking, the record is characteristic of mine haulage. One hour and 20 minutes out of the day is shown waiting on miners and 2 hours 2 minutes are spent in idleness or loafing.

I have observed many tests of mine locomotives with the object of developing such comparisons as the foregoing. I have never observed a single test—that is to say, a trial carried through the period of a day—that failed to show serious elements of time lost that could not be classed under the head of avoidable.

The elements of delay derived in Section I are also the basis of time wastage in the locomotive movement. In fact, as is readily appreciated, a delay which would prevent the prompt serving of a miner with cars would similarly as a rule reduce the efficiency of operation of

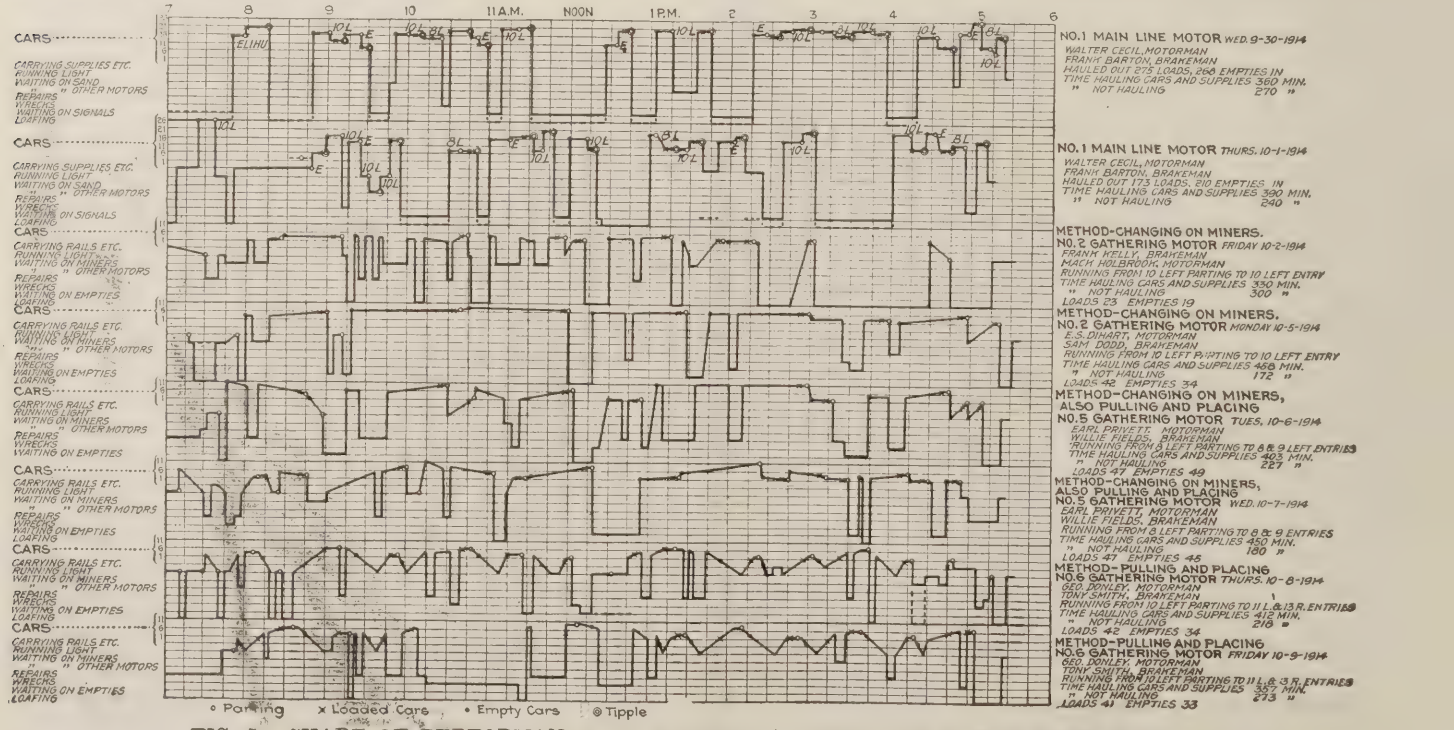

FIG. 5. CHART OF PERFORMANCE OF SEVERAL LOCOMOTIVES IN THE SAME MINE

the haulage system. There is also the factor of management which adjusts the movement of locomotive and cars to the requirements of the miner. Failure to properly make such adjustment will necessitate either the locomotive waiting on the miner or the miner waiting on the locomotive.

Fig. 5 is the chart of one day's work of several locomotives in the same mine. Such a chart can be easily developed for the entire haulage system so as to isolate the elements of avoidable time wastage. If such an analysis is properly prepared for and accurately conducted, it will usually be found that locomotives which were thought necessary can be done without. It will often be discovered that a mine is overequipped from a haulage standpoint. I have observed increases of more than 100 per cent. in productive effort following carefully conducted examinations of this character.

A locomotive is usually regarded as necessarily subject to frequent breakdowns incident to controller trouble, bearing trouble and armature burnouts. When these troubles are too frequent, the manufacturer is blamed. Nevertheless the manufacturers who supply a considerable proportion of mine locomotives in use likewise supply approximately 100 per cent. of street-car motors, which are in nearly all respects similar in design to the mine motor.

A street-car motor is supposed to last about five years before it becomes necessary to rewind it. During that period it is expected to do 200,000 car-miles. Provided a mine motor is of proper capacity for its work, there is no reason why its lasting qualities measured in period of time should not be equal to that of the street-car motor. The mileage, of course, will not compare.

Why Motor Trouble on Street Cars Is Rare

We all know how rare it is for a street car to stop on account of motor trouble. In spite of the number of cars in operation in a great city, a tie-up on account of trouble with a motor is a rare occurrence. The reason is that the rated voltage is supplied at all times and there is daily inspection.

I visited a number of mines in Germany some years ago in order to observe the mine machinery in use. On commenting upon a daily delay sheet that was kept, and the absurdly low repair cost as well as the small amount of time used in effecting repairs, I was advised that this was due to the daily inspection which all machinery underwent. The rule of the railways should be followed and the mine locomotive should be subjected to daily inspection by a competent man. The following parts should be examined with particular care daily: First, controller segments should be filed and greased with vaseline. Second, every bearing should be oiled and packed. Third, brushes and commutators should be watched carefully. Fourth, the distance between armature and pole pieces should be gaged weekly. If these parts are kept under observation in the manner suggested, locomotive troubles will become nearly negligible and actual breakdown in the mine will become practically unknown.

A suggestion in connection with the operation of the haulage system, which on its face may appear radical, is what might be termed a dispatcher system, corresponding to the system in use on all electric railways as well as railroads. We have reference to a man whose duty it would be to observe and systematize the movement of equipment in the mine and who would keep check on delays of the character recorded in Sections I and II. He should maintain a system of checks and charts which would throughout the day's work inform him as to the condition of the rooms and the relative location of cars, locomotives and machines. This man, if of the proper training, could also carry out or direct the tests and investigations recommended in the several sections. We have observed the partial adoption of this system in one or two cases, and the results have been gratifying. There is no question but that if the mines of the country would adopt such a system, and if competent men could be utilized for the work, exceedingly valuable results would follow in relationship both to cost and production.

There should be at the disposal of the mine officials or a dispatcher a comprehensive mine telephone system. A good telephone system is as necessary to efficient mine operation as it is to a trolley system or a railroad. It will increase production and reduce the cost. It is the opinion of coal properties in which telephone systems have been installed that these systems rapidly become essential to efficient handling of the mines.

Mines which have been equipped with telephone service, and these systems properly used, have shown marked increase in production through scheduling of main-line locomotives. The telephone tends to reduce the number of wrecks. It enables the mine foremen to keep in touch with each locomotive, making it possible for them to direct and control movements to advantage. We believe from observation of mines that have installed telephone systems that it is one of the best investments a mine operator can make. When properly installed, the maintenance is a small item.

(*To be continued*)

Legal Department

Federal Reservation of Coal Lands.—The provisions of the Federal land laws reserving "mineral lands" to the United States include coal lands. The statute enacted by Congress in 1894 granting sections 2, 16, 32 and 36 in every township to the State of Utah for the support of common schools, read in connection with other legislation, must be interpreted as excluding from such grant all section constituting mineral lands. (United States Supreme Court, United States vs. Sweet, 38 Supreme Court Reporter, 193.)

Damages for Personal Injuries.—An employee of a coal-mining company, in suing for injuries sustained while temporarily engaged in pushing loaded coal cars from a pit mouth to a check house at a daily wage of $2, was entitled to show that he was a skilled miner and able to earn higher wages under normal mining conditions. But it was improper to permit him to testify that he could earn from $6 to $7 a day, without any showing as to the prevailing wage scale for miners. And where plaintiff sought recovery for injury to his foot resulting from his stepping into a hole in the track along which he was pushing cars, it was improper to permit his witnesses to testify concerning the unusual or exceptional character of the hole, measured by general practices in coal mining, since that did not bear on the issue as to whether defendant was negligent or not. (Pennsylvania Supreme Court, Clark vs. Butler Junction Coal Co., 102 Atlantic Reporter, 952.)

Standardization of First-Aid Methods

By LIEUT.-COL. C. H. CONNOR*
Medical Corps, United States Army

As Chairman of the Committee on Standardization of First-Aid Methods and Rules for Conducting and Judging First-Aid Contests, Lieutenant-Colonel Connor submitted to the Seventh Safety Congress of the National Safety Council, held at St. Louis, Mo., Sept. 18 and 19, 1918, a report summarizing the work accomplished in connection with the committee's effort toward the standardization of first-aid methods. In presenting the report certain facts were cited, among which were the following: Preliminary letters were sent to the members of the committee, with a copy of the Red Cross circular describing first-aid contests. The rules and suggestions contained in that circular have proved satisfactory to the First-Aid Division of the American Red Cross in competitive events, and it was suggested that they be adopted as standard by the Mining Section of the National Safety Council. Replies to the letters were received from all but two members of the committee and a digest of the comments is contained in Lieutenant-Colonel Connor's remarks.

SINCE the last annual meeting of the National Safety Council a census has been taken of the opinions of industrial surgeons in reference to organizing first-aid teams in industrial concerns, the giving of prizes and medals for excellence in first aid among employees, and the holding of first-aid contests. Nearly all favor and indorse such methods.

In reference to organizing first-aid teams, some members of the committee are of the opinion that it should be compulsory, especially in hazardous occupations; others say that it is not required in small industrial establishments. The point is brought out that organized team work greatly stimulates the study of first aid, adds to the interest manifested and ultimately leads to prevention of accident. The unfavorable criticisms received were not altogether explicit. One industrial surgeon replied: "It is better to employ nurses"; another gave the opinion that it might lead to something being done which would later be regretted.

The majority of your committees—industrial surgeons and first-aid men—approve of giving prizes. A large number express a preference for medals rather than a cash prize. "It is a splendid idea and men are proud of these trophies"; "It is an incentive to greater energy and effort, and results in more efficient workers"; "has worked satisfactorily in the mining region," and similar expressions are read. "Give cash prizes and certificates of merit; medals should be reserved for big deeds," is another individual expression. Unfavorable comment was as follows: "Trade to commercialize man's duty to his fellowman" and "highest efficiency should be reached purely from the standpoint of relieving the suffering of a fellow employee."

The favorable comments far exceeded the unfavorable ones as to holding first-aid meets in companies, at which different first-aid teams may compete for the prizes. By stimulating a healthy rivalry first-aid meets make for greater efficiency and improve both individual and team work. They develop technique and lead to an exchange of ideas; the results obtained are well worth the effort in every way. The meets are particularly advantageous in mine rescue work and in industries where team organization is essential. One member cites the fact that exhibitions are to be favored, but not contests, as the latter provoke trouble. Another favors contests of this character, but opposes the giving of prizes. Unfavorable criticisms are that rivalry is gallery play, that it belittles the purpose and nothing is gained, and that it does not give a chance to the best, who are always modest and timid. Several surgeons state that the performance of a plain duty to one's comrades should not require reward.

Inter-Company and Inter-State Meets

As to whether or not inter-company and even inter-state meets are productive of good results in maintaining interest in first-aid instruction, about one-fourth of the replies to the letters received indicate that the writers do not approve the idea of holding either inter-company or inter-state meets, while a few express their preference for inter-company contests. A majority, however, indorse the meets as outlined in the letter. In the opinion of one member, such meets result in an exchange of ideas and cause greater interest in the subject, thus tending to broaden and perfect the system and ultimately leading to standardization of first-aid methods. Another states that the spur of competition is helpful, while a third believes that a national association for first-aid instruction might be the outcome. Those who are opposed to first-aid contests say such meets are neither necessary nor practicable, that it is too difficult to put this kind of efficiency on a competitive basis, or that such contests should be limited to boys and girls, that they are not suitable for workmen.

E. E. Bach, director of the sociological department of the Ellsworth Collieries Co., has called attention to a "bone of contention" among safety men in the appointment of judges for first-aid contests. In the past it has been recommended that all such judges be physicians. Mr. Bach makes a good suggestion—that men who have completed a first-aid course and show a good general knowledge of first aid be permitted to act as judges as well as physicians.

C. E. Pettibone, chief safety inspector of Pickards Mather & Co., suggests that members of first-aid teams be limited to laboring men only, and that men should be taught to rely entirely on measures they can improvise from the materials at hand. The opinion of industrial surgeons to this question is unanimous, all believing that students should be taught to be able to improvise suitable materials when regular supplies are not available.

W. A. Lynott, in his Bureau of Mines manuscript, recommends that first-aid teams be selected with great care and with the thought that the men will remain in the employ of the company for years.

As to the advisability of permitting first-aid instruction to be given by other than physicians, the majority of opinions received regarding this matter are in the

*In charge of First-Aid Division, American Red Cross, Washington, D. C.

negative, the principal reason cited being that the layman cannot answer intelligently and correctly questions which may be asked during the course of instruction. A large number, however, agree that the first-aid instruction may be given with very satisfactory results by a thoroughly trained and experienced first-aider or graduate nurse. Some of the statements are amplified in the following manner: "Instruction should be given by a physician, but it is highly desirable to standardize the courses so that definite and prescribed teaching shall be followed; the entire course to be kept simplified and not left to the individual judgment of the instructor as to what shall be included or omitted." "First-aid instruction to be of value must be given by one who thoroughly understands the subject." "Intelligent first-aid instruction requires a considerable knowledge of anatomy and some physiology and symptomatology; a layman is not often in possession of this knowledge." "Physicians, unless they have spent considerable time in informing themselves on first-aid work, are not qualified to teach it as it should be taught today; furthermore, they do not always have sufficient time to devote to the subject. A salaried, well informed, first-aider with teaching ability, spending his entire time at the work, talks to employees in a language which they can understand, not 'over their heads.' He drills them personally and obtains results." It is recommended, however, that previously prepared lectures on first aid should be given by a physician, mentioning briefly details of anatomy and physiology, and presenting reasons why certain first-aid procedures should or should not be followed. The advisability of giving elementary instruction in anatomy and physiology in a first-aid course is not questioned.

First-aid treatment is meeting the basic and immediate requirements of the sick and injured from an anatomical and physiological standpoint. As the life of an injured person often depends upon the care he receives from the first individual to aid him, it is important that people be taught the rudiments of physiology, anatomy and the principal factors to be met in an injury. For instance, in resuscitation, something of the mechanism of the respiratory apparatus should be taught; in the control of hemorrhage, knowledge of the location of the most important and vulnerable blood vessels is necessary.

In furtherance of first aid and accident-prevention work, and the dissemination of knowledge in the homes of the workmen, it is recommended that all employees should be instructed by lectures and demonstrations and also by giving them textbooks.

Did Rope Break from Sudden Jerk?

On the morning of Sept. 10 a cable broke at the Protection shaft of the Canadian Western Fuel Co., Nanaimo, B. C., and 16 men were plunged to their deaths. An inquest was held at Nanaimo on Sept. 12 by Coroner Hickling. He soon came to the conclusion that by delaying the inquest till Oct. 22, valuable information as to the condition of the rope at the time of the disaster might be obtained, and, in consequence, postponed the hearing till that time.

William Fleet Robertson, provincial mineralogist, has been sworn in as an official of the court, and he will take the broken cable to eastern Canadian laboratories where he will have "critical microscopic and chemical" examinations and tests made under his supervision. He is also taking samples of the water which flows into the shaft so that he may have it analyzed to ascertain whether it contains any matter likely to cause rope corrosion or deterioration.

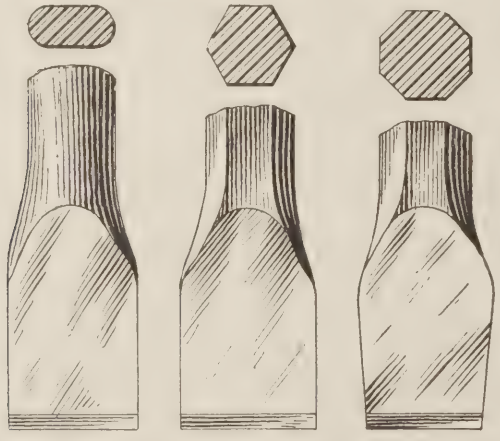
James Menzies, rope expert, who is employed by the Canadian Western Fuel Co. to examine, at regular intervals, all cables in use in the company's mines, was one of the chief witnesses. He informed the court that he made an inspection of the cable once a week. His last inspection was made on Sept. 4. On that occasion he had passed the cable as was his custom through his closely gripped hand for its full length. Had there been any broken strands then he would have noted them, either when they struck his flesh or met his eye. He also said that his practice was to inspect the safety clutches and that he had found these, also, in good working order during his last visit.

Entire Rope Was Not Inspected

Another important witness was C. Wallbank who, until Aug. 28, was employed by the company to make the daily inspection of cables, etc., required under the terms of Section 91, General Rule 36, of the Coal Mines Regulation Act. On the date indicated he had left the service of the company. Up to that time he had made the daily inspection required and filed the necessary report. He had never found anything wrong with the rope in question. It appeared, from the evidence of C. Nicholson, that the latter took Mr. Wallbank's place. The former swore that he had inspected the cable and the cage, but on cross-examination it was found that this inspection was only of the 50 ft. of the cable immediately above the cage, whereas his daily report would lead to the belief that it extended the full length.

S. Tembey, the engineer in charge of the operation of the hoisting machinery at the time of the break, swore that he was not using steam or brakes at the moment the cable gave way. William Woodman, an engineer of 30 years' experience, argued that the application of brakes could not have been the cause of the breakage of the rope, because it was evident that the rope broke when the cage was only one-quarter way down and at that point there could be no advantage in applying the brakes. He came to the conclusion that the rope broke at the point stated by him because it snapped 157 ft. from the cage and the shaft was 650 ft. deep. The inspector of mines, J. Newton, stated that he inspected the mine once a month, but did not inspect the ropes himself.

William Woodman in the afternoon of Sept. 13 admitted that he had heard the men make complaints as to the jerky way in which they were lowered at the Protection shaft. When the attorney asked for the names of these men Mr. Woodman refused to reveal them, declaring it unfair to give hearsay evidence. On an appeal made by the attorney to the parties in question, several of whom were said to be in court, one of them corroborated the statement. The doors were then closed and all the miners who had descended the shaft were put on the stand and sworn. Some corroborated the statement that there were complaints made about the manner in which the cage was jolted.



The Cold Chisel

By J. A. LUCAS
Ozone Park, New York

SYNOPSIS — *To the average layman a cold chisel is a cold chisel. This article shows, however, that there are cold chisels and cold chisels. The shape of a chisel is determined by the work to be performed and the kind and texture of the material to be cut. It is highly important to keep both ends of a chisel in proper shape if best results are to be secured.*

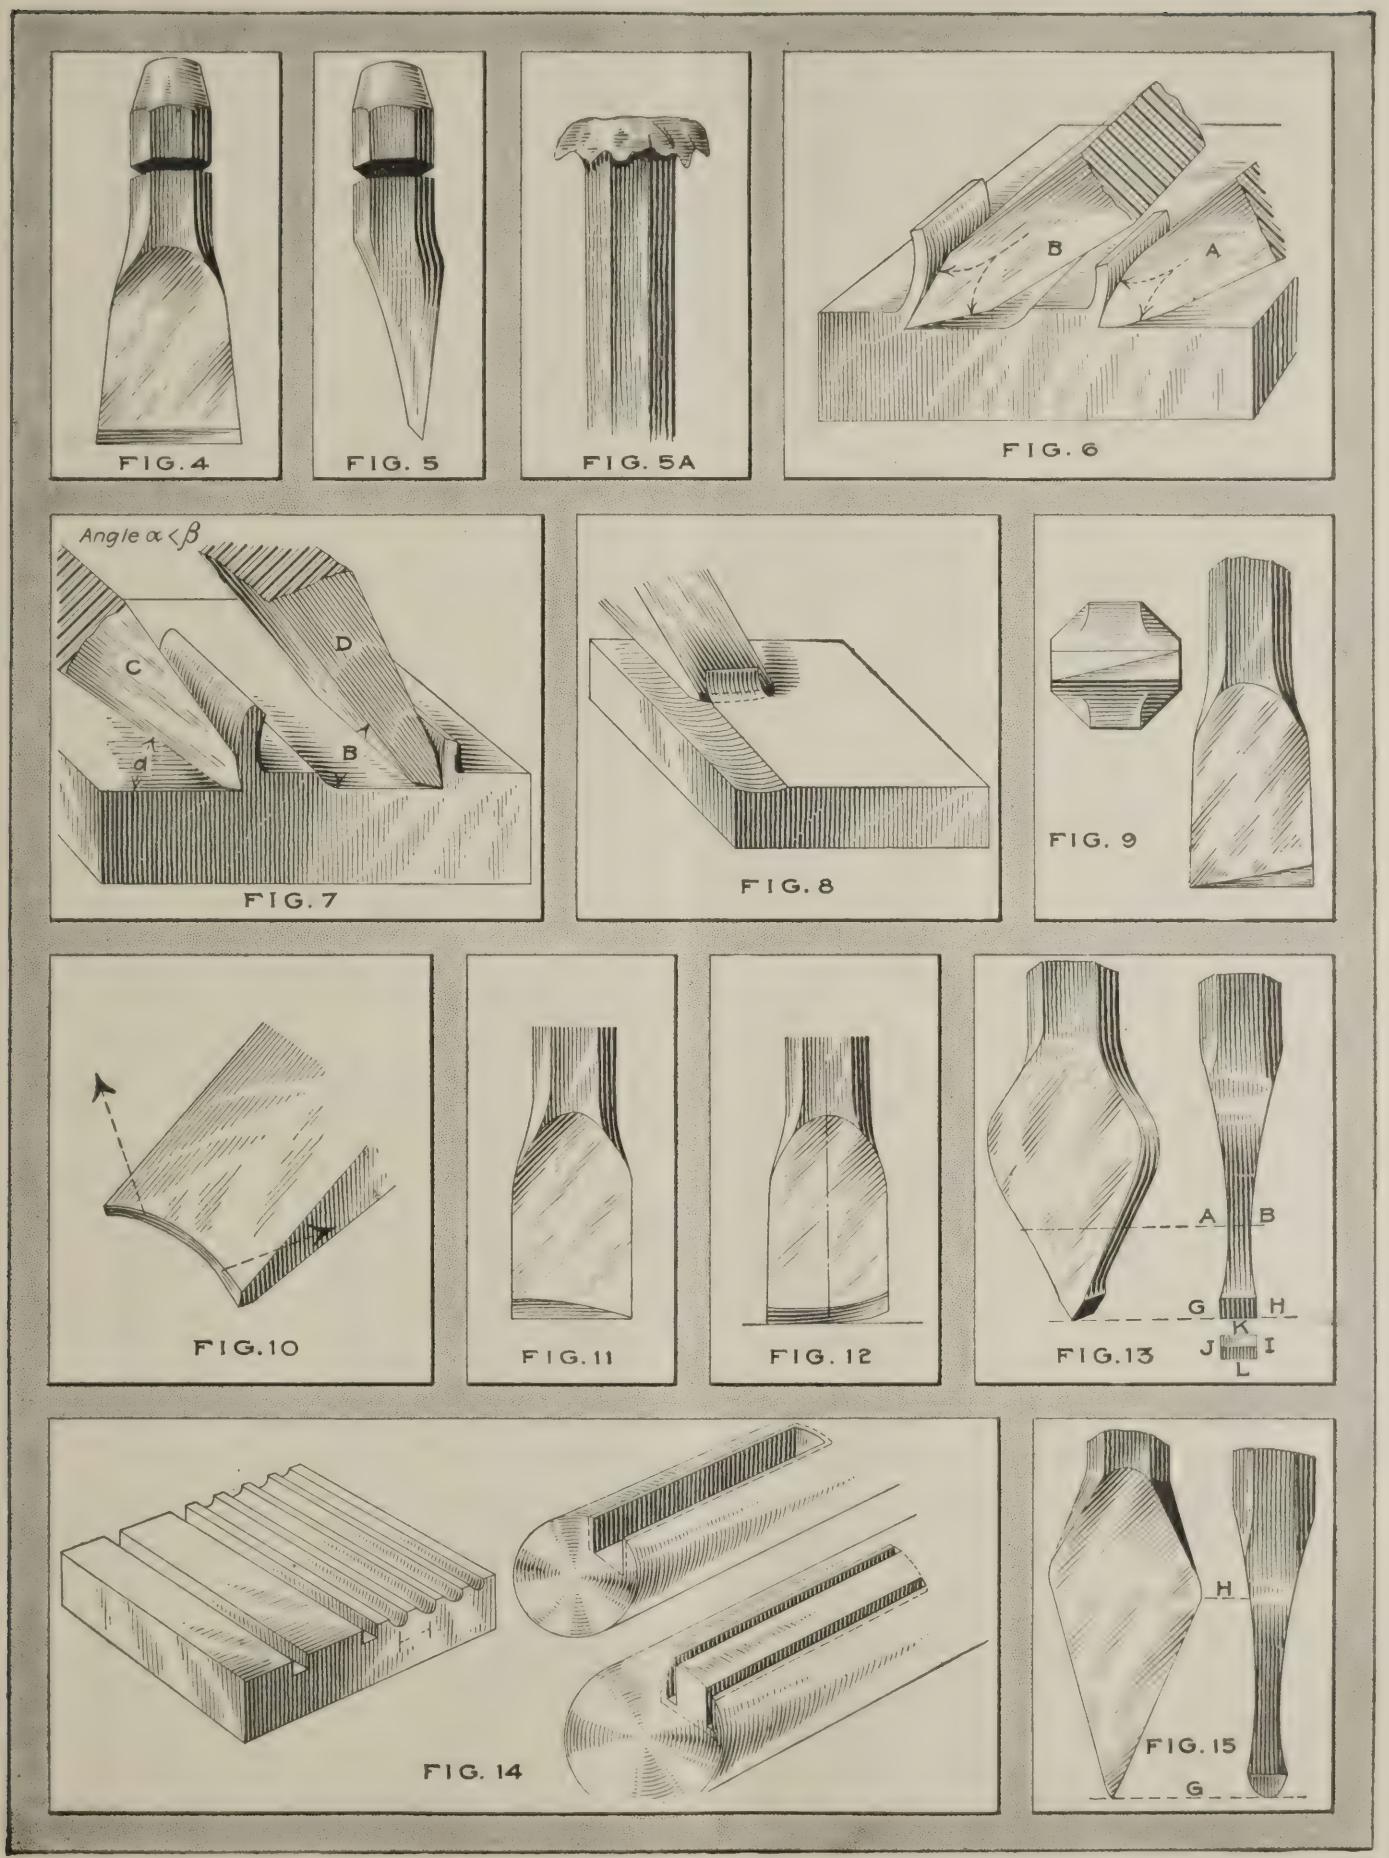
THE machinist's cold chisel is made from the three forms of steel shown in Figs. 1, 2 and 3. Of these the first is preferable, because it has two broad flat surfaces diametrically opposite which form guides to the eye in holding the chisel on the grindstone and aid in grinding the facets that form the cutting edge true. Furthermore, as the cutting edge is in a plane parallel to these flats, they serve as a guide to show when the chisel edge lies parallel to the work surface. This is requisite in order to produce true and smooth chipping.

To make a chisel, a piece about 6½ in. long is first cut from the bar. One end is heated to a cherry-red heat and the head formed by slowly rotating the tool and hammering down the steel until the end becomes conical

FIGS. 1 TO 3. VARIOUS TYPES OF ORDINARY COLD CHISELS

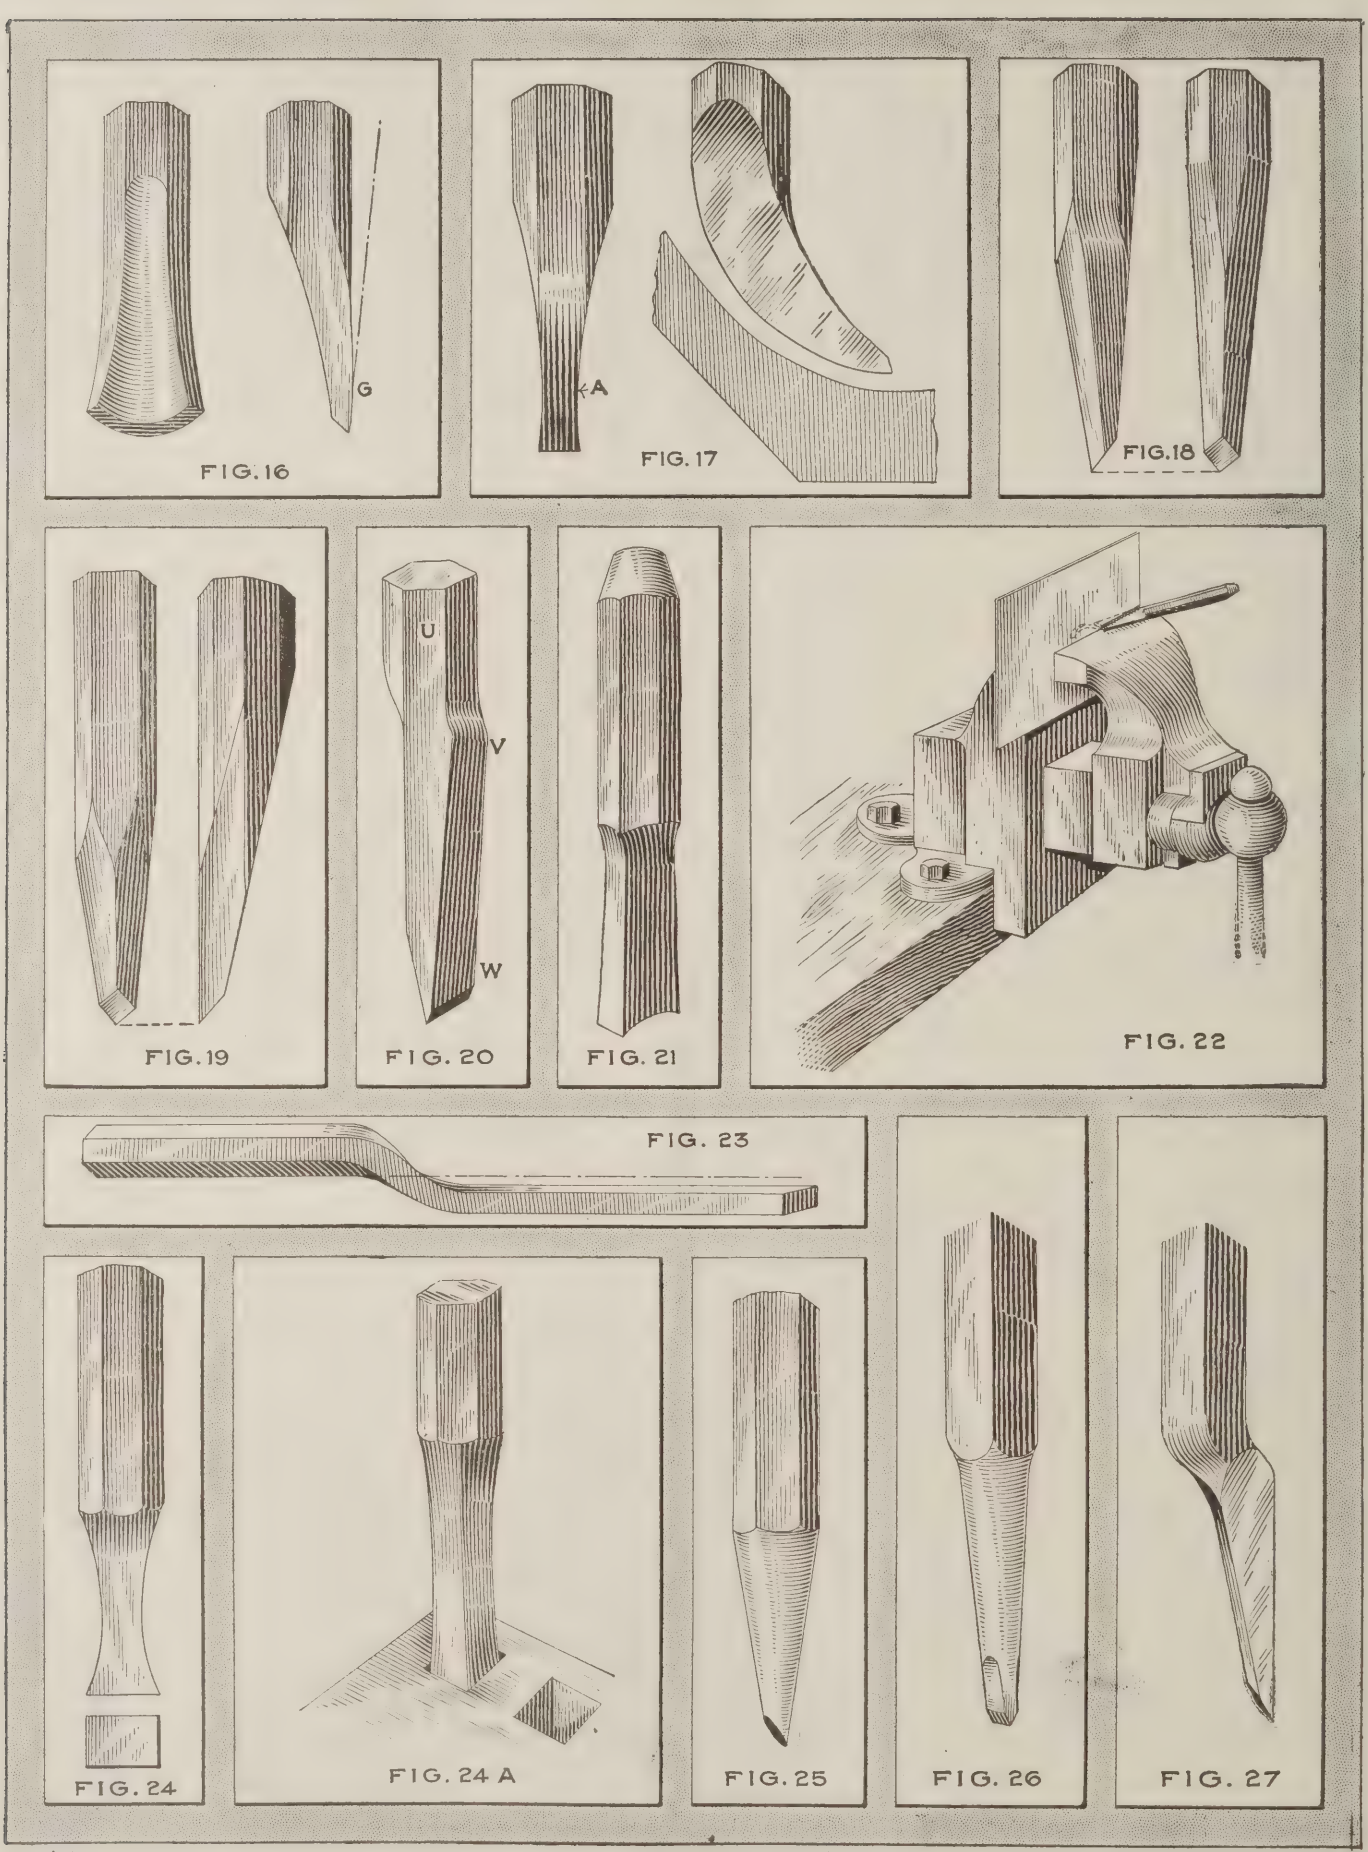
for a distance of about ⅝ in. The steel is now reversed, and after a heat about 1½ in. long has been made the metal is drawn down to a wedge shape, care being taken to keep the edges from spreading.

It is important to note that the under side of the chisel lies flat on the anvil, and a flatter or smooth set-hammer should be used toward the end of the process to smooth the work. If possible the chisel should be made in not more than two heatings, in order to maintain the original hardness in the steel. The finished forging should be allowed to cool off on the anvil while steady light hammer blows are struck upon it near the cutting edge. This operation renders more dense the molecular structure of the steel and greatly increases the life of the tool.



The chisel of ordinary size should measure between 8 and 9 in. over all, assuming that it is made from a bar of octagonal steel measuring ⅞ in. across the flats. The width of the tapered portion should not exceed 1 in., and the sides should be parallel for 2½ in. in a tool intended for general work, as shown in Fig. 2. For hard metal a chisel should be slightly tapered toward the point (Fig. 3), and for soft metals it should be bell shaped, as shown in Fig. 4. Soft metals are cut or chipped without lubrication, but wrought iron and steel yield far better results when the chisel edge is first rubbed on a piece of oily waste.

The width of the chisel may be made greater (as in Fig. 4) for use on brass or cast iron than when intended for wrought iron or steel, as on account of the toughness and hardness of wrought iron and steel the full force of a blow from a 1¾-lb. hammer, having a handle 13 in. long, may be struck on a chisel about ⅞ in. wide without danger of causing the metal to break out below the chipping line; but if such a chisel be used with full-force blows upon cast iron or brass the metal is liable to break out in front of the chisel, the line of fracture often passing below the level that it is intended to chip down to. Hence if a narrow chisel is used lighter blows must be delivered. By using a broader chisel, however, the force of the blow is distributed over a greater length of cutting edge, and full-force blows may be employed without danger of breaking the metal.



The cutting end of the chisel should be ground thin, as in that case it cuts both easier and smoother. The total length of a chisel, when new, should not exceed 8 in. If made longer it is not suitable for heavy or smooth clipping, as in that case it will bend and spring under heavy blows and cannot be held steady. The forged part should not exceed 2½ or 3 in. in length, as a long taper is highly conducive to springiness, whereas solidity is of great importance both to rapid and smooth work. The facets forming the cutting edge should be straight throughout their widths, as at *B* in Fig. 6, and not rounded as at *A*. Straight faces permit the face next to the work to form a guide in holding the chisel at the proper angle to maintain the depth of the cut. This angle depends upon the nature of the material to be chipped. The more acute the angle, the better the chisel will cut and the less will be the effort of raising the chip, thus increasing production.

From the viewpoint of economy, one would be tempted to reduce this angle to a minimum. But we have to consider the resistance and durability of the tool, and make the angle according to the toughness of the material to be cut. The cutting angle may therefore safely be made 65 deg. for machine and other kinds of steel, 50 deg. for cast iron and brass, and 30 to 35 deg. for copper, babbitt and lead.

The more acute these angles the nearer will the body of the chisel lie parallel with the work and the more effective will be the hammer blows. Thus in Fig. 7 chisel *C* shows the position of the tool for wrought iron, while position *D* shows that for steel. The edge angle should always therefore be made as acute as the hardness of the material will permit. If such an angle is too

FIGS. 4 TO 15. VARIOUS SHAPES OF CHISELS AND EXAMPLES OF THEIR APPLICATION

FIGS. 16 TO 27. SPECIAL FORMS OF CHISELS AND SOME OF THEIR USES

acute, the cutting edge will be apt to bend, while if not sufficiently acute it will not cut keenly; hence the object is to make this angle as acute as possible without causing the cutting edge to bend or break throughout its length.

The cutting edge should be slightly rounded in its length. This will strengthen it and also enable a fine finishing chip to be taken, as in Fig. 8, the width of the chip not extending fully across the chisel width. Thus the corners are not under duty and are not, therefore, liable to break or dig in and prevent smooth chipping. In some practice the edge is made straight throughout its length, as shown in Fig. 2. This is permissible in heavy chipping when a cape chisel has been used, but in any event an edge rounded slightly throughout its length is preferable. If the edge is hollowed, as shown in Fig. 10, the chip acts as a wedge to force the corners outward, as denoted by the arrows. This may cause breakage under a heavy cut and, furthermore, a smooth cut cannot be taken when the corners of the chisel meet the work surface.

If the edge facets are ground less on one side than on the other, as in Figs. 9 and 11, the edge will not be parallel with the flats of the chisel, so that in holding the tool the flats will not form a guide to determine when the edge lies parallel to the work surface. Fig. 12 shows a wrongly ground chisel that will never cut parallel to the surface of the work. The edge at its center should also be at a right angle to the center line of the chisel, as denoted on the left half of Fig. 12, for if not at a right angle the chisel will be apt to move sideways with each blow and cannot be held steadily.

The chisel should be held as close to its head as possible, so that the hand will steady the point where the blow is received. The tool should be pushed forward firmly and steadily to its cut. This will greatly facilitate rapid and smooth chipping. When working on wrought iron and copper it is found better to occasionally moisten the chisel with oil or turpentine, the former being preferable.

The head of all chisels should be dressed round and somewhat reduced in diameter, as shown in Figs. 4 and 5. When the head becomes battered, as in Fig. 5A, it should be redressed as small pieces of steel are apt to fly from a bushed chisel head, embedding themselves deeply in the hand holding the chisel.

The flat chisel can be modified in form to suit special conditions, as, for example, the cutting of the flat sides of a mortise require a chisel the axis of which will follow a line nearly parallel to the work surface. Such a chisel is shown in Fig. 5, in which one flat is parallel with the length of the chisel, having at the end one wide facet at a slight angle with the length. This is done in order to be able to guide and control the cutting edge of the tool.

All that has been said respecting the flat chisel applies equally well to the cape chisel, except that the sides at right angles to the cutting edge are narrower than the shank and that the sides parallel with the cutting edge are spread wider where they join the shank, as in Fig. 13. The cape chisel will cut up some ugly capers if not properly forged and ground. If not made narrower at *AB* than at *GH* it will, when the corners wear dull or tapering at *GH*, wedge and possibly split a frail piece on which it is being used to cut a slot. Referring to the end view, if the sides *IJ* are not ground approximately at right angles with *KL*, the chisel will twist and hang, and cannot accurately be guided in a slot or keyway.

When cuts of $\frac{1}{8}$ in. or deeper are to be taken, it is necessary to precede the flat chisel by grooves cut with a cape or round-nosed chisel. The distance apart of these grooves should be less than the width of the flat chisel, thus leaving strips to be chipped by the latter. This method is used in chipping broad surfaces, but is unnecessary when the area is quite small. The surface shown in Fig. 14 represents this preparatory grooving. Besides the uses above given, the cape chisel is employed for cutting keyways in shafts, pulleys, gears, etc., also for cutting slots.

In cutting a keyway with the cape chisel, if the keyway be made, say, $\frac{5}{8}$ in. wide, the cape should be about $\frac{1}{32}$ in. narrower. The remainder of the keyway is removed by a file. If the keyway be $\frac{3}{4}$ in. or wider, it is

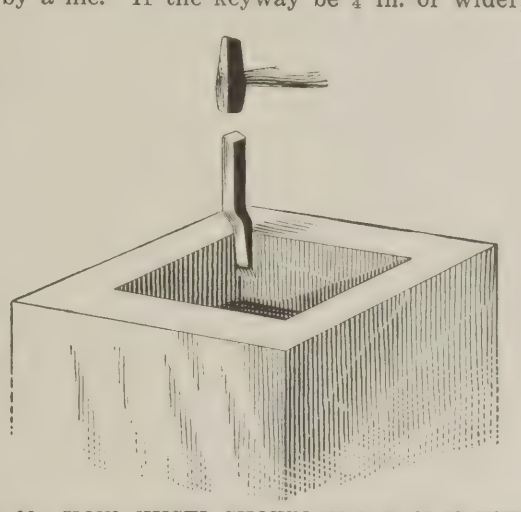


FIG. 28. HOW CHISEL SHOWN IN FIG. 27 IS USED

better to use a cape chisel less than half the width of the keyway and cut two grooves.

The round-nosed chisel, Fig. 15, may be straight from *H* nearly to the point *G*, but should be bevelled near *G* so that the head of the chisel may be raised or lowered to govern the depth of the cut. The round nose should also be wider than the metal higher up, so that the chisel head may be moved sideways to govern the direction of the cut, as is the case with the cape chisel.

The cow-mouth chisel, Fig. 16, should be bevelled from *G* to the point, so as to permit governing the depth of the cut. It should have a greater curvature than the corner it is to cut out, so that its corners cannot wedge in the work. The name of this chisel is derived from its curved shape; a better name, one not infrequently used, is "gouge," on account of its similarity to the wood-cutting tool of this name. This tool is used for enlarging holes or for chipping curved surfaces.

The oil-groove chisel, Fig. 17, should be wider at the cutting edge than at *A* for reasons similar to those given above, and of less curvature than the bore of the brass of bearing in which it is to cut the oil groove.

The diamond-point chisel may be made in two ways. First, as in Fig. 18, for shallow holes, or as in Fig. 19, for deep ones. In shallow holes the chisel can be leaned over, whereas in deep ones it must be held straight so that its body may not meet the other side of

the hole, slot or keyway. The form shown in Fig. 18 is the strongest, because its point is brought into line with the body of the steel. The side chisel, Fig. 20, for cutting out the sides of keyways or slots, should be bevelled from *W* to the cutting edge for the reasons already given, and straight from *W* to *V*, the line *VW* projecting slightly above or beyond or outside of the body *U*. All these chisels are ordinarily tempered to a blue color.

The ripper, shown in Fig. 21, is a necessity to the repair machinist for cutting off boiler tubes, tanks, sheet metal, etc. The shape of the cutting blade is on the style of that of the cape chisel. The cutting edge is slightly hollowed to guide the tool in the course of cutting. Sheet metal held in the vise may be much more easily sheared with the ripper than with the ordinary flat chisel. This process is shown in Fig. 22.

The drift, Fig. 24 and 24A, is a tool that is sometimes used instead of a file for enlarging or correcting square, rectangular or polygonal holes. The drift has no cutting edge proper, but the end is at right angle to the body and cuts on the same principle as the punch used in punching holes in boiler plates, or somewhat like the ripper mentioned above.

The key drift is for driving keys out of pulleys, gears, etc. Like the drift, its small end is rectangular in cross-section, but it is not intended to do any cutting, as shown in Fig. 23.

The round-nosed chisel, Fig. 25, and the flat chisel, Fig. 26, are small size and used on light work. The chisel, Fig. 27, is fit for deep, internal work, and is shown in use in Fig. 28.

In tempering chisels for general use they should be drawn nearly to a blue, which gives a tough temper that will stand up well on all metals except chilled iron and hard steel. For these latter metals, in drawing the temper the chisels should be plunged in water just at the time the color starts to change from straw to blue. In exceptional cases a bright straw color is kept, but in use hammer blows must be comparatively light, otherwise the brittle edge will fail.

No matter how carefully a chisel may be tempered it may be softened in a few seconds by overheating the edge at the emery wheel. To avoid this a constant flow of water may be directed to the point of the chisel when grinding. If an automatic water supply is not available, the chisel must be frequently dipped in a can or other container filled with water.

Possibilities of Using Peat as Fuel

In view of the dangers of another coal shortage the Director of the U. S. Geological Survey calls attention to the practicability of using peat as fuel in some localities and offers some suggestions as to the preparation, storage, value and use of peat.

Vast deposits of peat that could be converted into fuel are found throughout Minnesota, Wisconsin, Michigan, New York and the New England States, and in the northern parts of Iowa, Illinois, Indiana, Ohio, Pennsylvania and New Jersey, according to C. C. Osbon, of the Geological Survey, who has recently been studying this subject. Many peat beds occur also on the Atlantic coastal plain from New Jersey to southern Florida and westward along the Gulf coast to the Mexican boundary. This coastal plain is rather remote from the known coal fields and contains few other mineral fuels. The preparation and storage in farming communities and villages of peat fuel taken from these deposits by the owners of small bogs and by citizens' associations for distribution among their members would not only increase the local fuel supply and in many localities prevent a recurrence of the suffering caused by our recent coal shortage, but would release railroad cars that will be vitally needed for other purposes.

Fuel Value of Peat

Peat, or muck, as this mineral is frequently called, consists of partly decayed plant remains that contain enough carbon to ignite and burn freely when dry. In texture it ranges from a fibrous, imperfectly decayed kind, through progressive degrees of decomposition, to a thoroughly disintegrated type, and varies correspondingly in color from light yellow to jet black.

Peat in an undrained bog contains about 90 per cent. of water, which must be reduced to 30 per cent. before it can be used for fuel. By thoroughly draining the deposit approximately 10 per cent. of the water in the peat may be removed, but the remainder, which is held in microscopic plant cells and minute intercellular spaces, can not be reduced below 70 per cent. without drying in the open air or in a heated chamber. Artificial drying, however, requires so much heat in comparison with that obtainable from the fuel prepared by this process, that so far as the U. S. Geological Survey is aware, it has not proved commercially feasible.

The value of a given deposit of peat as a source of fuel is dependent on many factors, most important of which are degree of decomposition, heating value and ash content. Coarse-textured fibrous peat makes fuel that is inferior to the black, compact, thoroughly decomposed kind, unless that kind contains a large proportion of ash. The maximum quantity of ash that is usually considered allowable in peat for commercial use has been placed between 20 and 25 per cent., but if the content of ash exceeds 20 per cent. of the total weight of the dry peat it is scarcely worth the labor of production, even for home use. The heating value and ash content of peat fuel intended for domestic consumption may be determined by a simple practical test. A typical sample should be taken from the bog, thoroughly macerated, dried and weighed. If, when burned in an ordinary heating stove, the heat generated is almost equal to that produced by bituminous coal, and after complete combustion the weight of the ash does not exceed 20 per cent. of the weight of the dry peat before burning, its usefulness as a fuel for domestic purposes is established.

Methods of Preparation

The season for drying peat begins about Apr. 15, or as soon as the frost is out of the ground, and ends in September, except in the southern peat region, where it is somewhat longer. Present industrial conditions in the United States prohibit the manufacture of large-capacity peat-fuel machines for operation this year, as such machinery, on account of the small demand in this country, has to be specially designed and constructed. It seems, therefore, that peat intended for use next winter will have to be prepared either by hand or by

existing machinery that can be readily converted to use for producing peat fuel.

The hand-cut process of preparing peat, which is widely used in Ireland, seems most practicable for the owners of small deposits in the United States. Before this method can be used the deposit must be thoroughly drained and cleared, and the turf removed from its surface. Most bogs of the built-up type—that is, those which were formed by the deposition of the remains of plants that grow near the ground-water level—can be drained to the bottom by a simple system of surface ditches. Lake bogs, in which the deposit has accumulated below a permanent water level, can not generally be drained far below the surface of the peat without incurring great expense, and are therefore not so well adapted to hand digging as built-up beds. However, many lake bogs in the northern peat region, where most of the marshes in which this mineral has accumulated were formed during the Wisconsin or last glacial stage, may be sufficiently drained for peat recovery by means of a short drainage canal connecting the edge of the basin at the lowest level with an adjacent stream.

How the Peat Is Dug

After the surface of the bog has been cleared the peat is dug in brick form with a special tool called a slane. This instrument, which can be made by a blacksmith, is a narrow spade with a sharp steel lug welded on one side at right angles to the edge of the blade. The blocks of peat range from 8 to 10 in. in length, from 4 to 7 in. in width, and from 3 to 6 in. in thickness, their dimensions depending on the size of the slane. As they are dug they should be removed to the drying grounds and stood on end or placed on covered racks. At the end of about four weeks, during which they should be frequently turned until their moisture content is reduced to about 30 per cent., the blocks are usually ready for storage. As cut peat absorbs water rapidly, great care should always be taken to protect the dry blocks from rainfall. Peat fuel prepared in this way is bulky, easily crushed, and burns rapidly with considerable waste. In heating value it is superior to wood, but it is unfitted for commercial use.

To produce peat fuel of better quality and in larger quantity than is possible by hand, the machine process should be used. This process, which should be practicable for the use of citizens' associations desiring to prepare fuel for distribution among their members is, so far as known by the Geological Survey, the only one that has proved commercially successful in Europe. The machinery for a small plant is simple and could be quickly obtained and easily operated. It consists essentially of an excavator and a macerator. The steam shovel could be used for digging peat from drained deposits; the dipper dredge is well adapted to removing this mineral from undrained deposits. The purpose of the macerator is to grind the constituents of the wet peat into a homogeneous pasty mass, which may be shaped into compact blocks. In principle and form the latest types of such machines are similar to the pug mill or grinding machine for plastic clay. Many of the experimental plants in the United States have used brickmakers' pug mills, with very slight changes, to grind peat, and they have proved to be well suited for the purpose. These machines may be readily obtained from dealers in clay-working machinery. After being thoroughly macerated the peat should be shaped into blocks as it issues from the machine or spread in a layer, from 8 to 12 in. thick, on the drying grounds and the bricks marked off by hand as the spreading proceeds. When partly dry they are loosely stacked or placed on drying racks and thereafter handled the same as cut peat.

A specially designed and constructed machine must be used for the production of peat fuel for market. Such a machine consists of a receiving hopper attached to a vertical or horizontal cast-iron body, in which revolve one or two knife-armed shafts. These shafts are also provided with spirally arranged flanges for moving the peat to the grinding knives and advancing it to the device for cutting it into bricks of uniform length as it issues from the orifice of the machine.

Machine peat that is allowed to dry slowly contracts into a dense mass covered by a gelatinous skinlike substance called hydrocellulose. After the moisture has been reduced to about 25 per cent. this coating renders it impervious to water, even when immersed. Peat manufactured by this process makes excellent fuel. In heating value a ton of machine peat is equal to about 1.3 tons of wood, seven-tenths of a ton of good bituminous coal, or half a ton of anthracite. Despite the disadvantages of cut peat, air-dried machine peat is well adapted for domestic use. It is clean to handle and burns freely, yielding an intense heat and producing no soot or other objectionable deposit. For open grates this fuel is nearly ideal, and it is said that peat may be burned in the same stoves as coal and wood. However, the best results could probably be obtained by burning it in a stove with relatively small grate openings and a restricted draft.

PUT YOUR CUSH IN THIS BIG PUSH

How Prices of Bituminous Coal Were Fixed by the Fuel Administration*—II

By CYRUS GARNSEY, Jr., R. V. NORRIS and J. H. ALLPORT
Engineers to United States Fuel Administration

THE great mass of cost figures, obtained from the analysis of the cost of operators mining over 95 per cent. of the entire production of bituminous coal in the United States, would be merely confusing and of but little practical value if presented in tables of figures and it was considered necessary to devise some plan to present these graphically so that they might be studied and compared with a minimum of effort and with maximum efficiency. After many trials, a chart was evolved which appears to have satisfactorily accomplished the ends sought.

The costs for each district, both exactly as reported and as adjusted were arranged in order by 1c. increments, beginning at the lowest cost, with the tonnage at each separate cost, whether from one or more operations; the percentage of total tonnage at each cost was calculated, and the cumulative percentage beginning at the lowest-cost tonnage was obtained.

Charts.—The percentages thus obtained were plotted on 10 by 10 cross-section paper, resulting in a diagram like Fig. 1. The dotted line shows the costs reported, and the full line the adjusted costs. The percentage of the total output between, or up to, any limits of cost can be determined by simple inspection. The "bulk line," or line of indispensable coal which must be assured of a minimum profit, after study of the conditions and necessities of any district, can be properly located, and from this a minimum profit necessary for the district can be determined.

Bulk Line Required Careful Study

The "bulk line" is a matter requiring very careful study. Its location must be such as to conserve and encourage all necessary operations and thus assure the maximum coal supply from each district. It is almost invariably found that at the high-cost end of the diagram are collected most of the doubtful enterprises. These include: Mines which have failed under normal competitive conditions and have been reopened under the stimulus of the high prices preceding Government control; mines abandoned as exhausted and reopened for the few remaining pillars; new enterprises in the development stage; mines opened on beds so thin or of such poor quality that they could not operate under normal conditions; small mines on outcrop coal, often of poor quality, which have neither capital nor equipment for economical working; mines which have encountered faults or in which the coal has thinned or split, or the quality has so deteriorated as to prevent working at a reasonable cost; and, not the least of this group, mines so badly managed as to show unwarrantable cost of operation.

All these classes of mines are unjustifiable under war conditions. They use labor inefficiently. Often their records show less than half the tonnage per employee usually obtained in their district, and their elimination is an economical advantage to a district in releasing labor to more efficient mines.

In this high-cost group occasionally are found mines which have a coal of unusually high quality or fitted for special use, for which a market at prices above those of the district has always existed. Such mines, on proving their special conditions, may receive consideration for special prices sufficient to allow a fair profit on their higher costs.

After a study of all conditions the "bulk line" is located as far as possible to exclude the classes of operations above mentioned, and to include all mines operating economically and efficiently. The margin above the "bulk line" is sufficient to allow all but a very small percentage of the tonnage to be produced without actual loss, but with less than the minimum profit applied to all mines up to the "bulk line."

Charts Divulge No Secrets

The charts have the further advantage that they show all the costs of any district without divulging the costs of any operation, yet by a very simple system of confidential keys the position of any separate operation can be almost instantly found and its cost sheets located.

The charts have the further advantage that almost any desired information as to costs or tonnage, averages, totals within desired limits, margins, excessive and subnormal costs with the tonnage involved, and other items of information often required can be obtained very rapidly and with a minimum expenditure of time or labor. On one occasion, two members of the committee calculated in a single evening the weighted average costs, both reported and adjusted, for over three-fourths of the entire bituminous coal output of the country.

It is inevitable that mines should show wide variations in cost, due to the varying thickness and character of the beds worked, and to apply a single price to all the mines of a state would result in either allowing an unreasonable profit to those working the better and thicker beds, or absolutely put out of business the higher-cost districts.

Where an area examined shows wide variation of cost, it becomes necessary to employ some plan of separation, and to segregate into groups those mines operating under similar conditions. Such districting may be based on difference in beds, on thickness of coal, or by geographical and geological districts.

Districting by beds is only occasionally practicable, for the following reasons: (*a*) Variation in thickness and quality in the same bed. (*b*) Difficulty of identification of beds. (*c*) Splitting of beds, changing one thick bed to two or more thin ones. (*d*) Changes in mining conditions in the same bed, making radical differences in cost of mining.

*Paper presented at the Colorado meeting of the American Society of Mining Engineers, September, 1918. The first part of this paper appeared in *Coal Age*, Oct. 10, 1918.

Districting by thickness of beds seems at first glance the most logical method, but it has the fatal objection that, as nearly all beds become thin in places, two or more costs will be found in contiguous mines and often in the same mine. Further, this districting leads to gross profiteering, by attempting to classify mines by the thinnest coal, not by the average.

The terms "thick" and "thin" beds are particularly dangerous, as what would be considered thick in one region may be classed as thin in another, and the reverse; it is therefore manifestly undesirable for the United States Fuel Administration officially to designate any particular thickness as the dividing line between thick and thin.

Districting georaphically has the great advantage of making divisions susceptible of accurate description and eliminating all questions as to the proper price applicable to any colliery. It generally puts together mines having the same conditions and normally competing, avoids varying prices for coal of the same quality and character, and simplifies distribution and marketing. The difficulties in applying this method are greatest in fields where numerous beds of varying thickness and character are worked, resulting in considerable variations in price. It is also frequently difficult properly to classify operations near the borders of adjoining districts, and geographical districts are hence necessarily subject to some adjustment of boundaries.

Further, in designating districts, labor conditions are necessarily carefully considered. Neither miners nor operators wish to have the scale of wages changed in any mine by the throwing of such mine from one wage district to another, and before deciding on the boundaries of districts, it has been found essential to obtain the wage-scale and the boundaries of wage-scale districts. Further, it is found that in making up the wage-scales, some very accurate districting has been done, and maps showing these wage districts are of great assistance in the final determination of proper boundaries.

It is the practice of the committee to classify mines under study, first by counties or fields, and then to separate or combine them, as the case may be, to obtain districts containing, as far as practicable, mines operating under the same general conditions.

Diagrams 2 and 3 show the result of districting in an important territory producing about 75,000,000 tons of coal per year. Diagram No. 2 shows the costs for the entire area, and the very wide variations in cost due to different mining conditions are apparent. Diagram No. 3 shows the costs in the three districts finally segregated. These all permit price fixing without giving excessive profit, or putting the high-cost districts out of business, thus assuring the mining of the required tonnage of coal.

It will be noted in the three-district diagram that the low cost of No. 1 corresponds with the high cost of No. 2, and the low of No. 2 with the high of No. 3. If prices had been fixed on diagram No. 2, for the entire state, the "bulk line" would have been placed at about $1.90. This would have put the whole of District No. 1 and 36 per cent. of District No. 2, or a production of about 500,000 tons per month, above the bulk line, giving these regions an insufficient margin, and checking production, if not stopping it; at the same time it would have given to District No. 3, producing 5,700,000 tons per month, 30c. per ton or over $1,700,000 per month unnecessary margin. Similar conditions throughout the country have been handled in this manner.

FIG. 4. MAP OF WEST VIRGINIA, SHOWING PRICE DISTRICTS

It will also be noted that the variation between high and low costs increases with the higher-cost districts. The angle of slope of the cost line increases from No. 3 to No. 1. This results in a somewhat greater margin between the average cost and the "bulk line," which is logical and necessary. The high-cost mines, having greater expenses, need a larger margin to attain the same percentage of profit. As an example of the districting necessary in exceptional cases, Fig 4 is a map of the districts in West Virginia. On fixing prices for these, only seven different prices were found necessary for 13 districts.

The "bulk line" of the chart, with the margin added by the Fuel Administrator, gives the necessary realization for a district, but it does not completely fix prices.

The price for run-of-mine is usually fixed at the realization price, but where screening is desirable it is necessary to fix a spread of price so that the operator receives as much as 1c. or 2c. more for the screened product than for run-of-mine.

The tonnage of run-of-mine, prepared, and screenings for each district is obtained from the cost sheets; then the average division of the screened coal in percentage is computed and from this margins are determined which will permit screening but not too greatly stimulate the practice. For instance, if a coal will produce 55 per cent. prepared, and 45 per cent. screenings, an equal margin above and below the run-of-mine price would be indicated; but a coal which would produce 30 per cent. prepared and 70 per cent. screenings would need a much larger margin for prepared above run-of-mine, and a very small margin below for screenings.

If the "spread" is not correctly figured, the result is to make some combination unduly profitable, with the result that only that combination is found to be made. In some instances, run-of-mine from particular collieries shows a few cents margin over screened coal, and these collieries will produce run-of-mine exclusively. In other cases, prepared and screenings are more profitable, with the reverse result.

Unusual Sizes.—In many parts of the country it was found that special sizes were customarily made. In Illinois, for instance, a considerable amount of coal is sized, about in accordance with anthracite practice, into egg, stove, nut, pea and buckwheat, and in certain states so-called "modified run-of-mine," passing through 2, 3, 4, 5, 6 and 8-in. bars is a standard product. These specially prepared and modified run-of-mine sizes cost the operators something extra, and will only be made if the prices received yield a profit over the regular procedure. The Fuel Administration has met this condition by allowing special prices for specially sized coal, and for modified run-of-mine sizes, but all such prices are so calculated as to allow only enough profit on any combination to permit its existence and not enough to encourage the forcing of such size on consumers.

In price fixing of this sort, it is essential to obtain, from several independent and reliable sources, the percentages of the various sizes produced by screening from each coal likely to be used in this way, and carefully balance the costs, losses, and percentages of each size produced, to arrive at a proper price.

It is also necessary to evolve methods of preventing profiteering on special prices. For instance, it was found that after making sizes down to buckwheat from bituminous coal, in some cases the fine screenings, far below the standard mesh of the district, were run into the regular run-of-mine and sold at the run-of-mine price. This was handled by an order allowing a maximum of 30c. below *screenings price* for any mixture of the fine coal below 2½-in. mesh with any other coal. This is easy to police, as the mere report of sizes below the standard screenings mesh of any district involves the report of special fine screenings or "carbon" at the price 30c. below screenings, and if such is not found, it is assumed to be mixed with commercial sizes.

Margin.—The difference between the mine costs, arrived at as described above, and the price is the "margin." This is far from being the profit, as many items of expense necessarily incurred are not included in the mine price. Such are: (*a*) Selling expense. (*b*) Improvements. (*c*) Developments to increase output. (*d*) Excess of capital expenditures over normal costs. (*e*) Contracts at lower than "Government Prices." (*f*) Interest on bonded indebtedness. (*g*) Income taxes. (*h*) Excess-profit taxes. (*i*) Profit on investment.

None of these items is properly included in "cost of production" under normal conditions, but in a war situation it is practically impossible to obtain money to capitalize expenditures for excess improvements, and developments, which would normally be capitalized and properly included in the permitted depreciation, particularly as all such expenditures are made at from two to three times their normal costs; it is a serious question whether the "margin" allowed should not be made large enough to include at least this class of expenditures.

As our Government has been forced into this untried realm of price control by war conditions, it may be interesting to know the results. These, in general, are available only as applied to the latter months of 1917, before the labor increase, compensated for by the 45c. general advance in coal prices above referred to. Diagram No. 5 shows the average costs, "bulk lines," and prices fixed for practically all districts in the country, as of August and September, 1917, and covers about 84

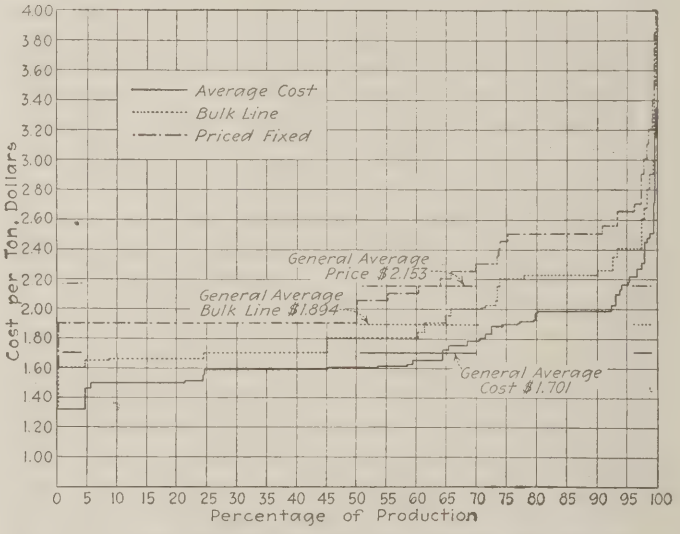

FIG. 5. AVERAGE COSTS, "BULK LINES" AND PRICES FOR ALL DISTRICTS

per cent. of the total output of bituminous coal for the period stated.

The costs for each district, in the proportion of its output to the total tonnage studied, are shown in full lines; the "bulk lines" are shown by dotted lines; and the prices fixed are indicated by dot-dash lines. The diagram also shows the weighted average costs, "bulk lines," and prices fixed for the tonnage included, and effectively disposes of the widely circulated aspersions of profiteering, of which the industry has been so freely accused by people having no knowledge of the facts or willfully misrepresenting them.

The weighted average margin between costs and fixed prices for practically the entire bituminous coal production of the country is but 45.6c., and between the "bulk line," which represents the higher-cost necessary coal,

and the price fixed by the Fuel Administrator of but 26c. When it is known that the capital invested per ton of yearly output ranges from $2 to nearly $8, and that the items above noted, which amount to a considerable sum per ton mined, must come out of this very narrow margin, it is evident that the coal business of the country is not only not on a profiteering basis, but is still on a very narrow margin of profit.

The average cost of the 84 per cent. of the total coal represented for the two months of August and September, 1917, was reported to be $1.696. The adjustments heretofore described raised this reported cost to $1.706, a very strong indorsement of the honesty of the reports made by the operators.

The average "bulk line" was fixed at $1.902, or 19.6c. above the average adjusted cost. This represents the

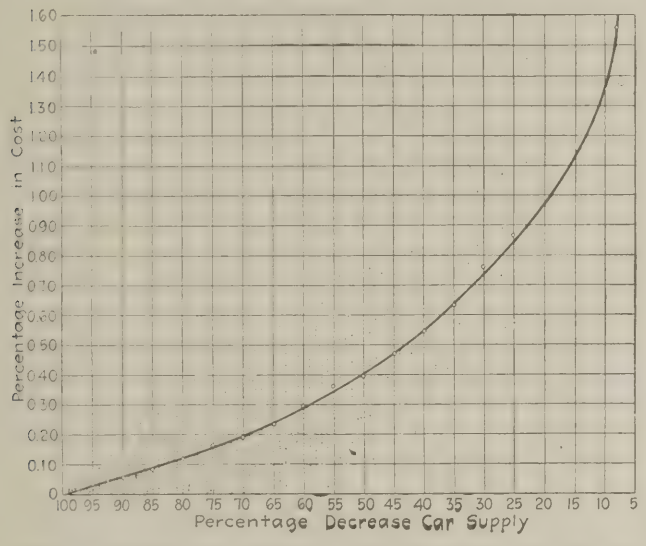

FIG. 6. INCREASE IN TOTAL COST OF PRODUCTION

margin required to assure the mining of the necessary coal, as compared with the average cost, which, of course, involves the mining of only coal up to or below the average cost; in other words, half the available output.

The weighted average of all prices fixed is $2.162 per ton and the average margin above the "bulk line" is 26c., representing all the above mentioned charges and all profit for the higher-cost necessary mines; the margin above the average weighted cost for the whole country is 45.6c. per ton, which, compared with profits in other businesses, certainly does not show any signs of profiteering in the coal business as a whole. The prices fixed are also sufficient, on the basis of the reported costs, to permit the mining of 98.4 per cent. of all available coal, without loss.

The prices fixed from this complete investigation of costs have shown, in many cases, a remarkable compliance with economic laws. For instance, in Illinois the cost of coal from the different price districts, delivered in Chicago, is found to be practically identical, showing that the mining of the higher-cost coal is due to its proximity to the principal market and the lower resulting transportation costs. High-grade coal shipped by lake and rail to Minneapolis was found to cost precisely the same per heat unit as a lower-grade coal shipped a much less distance all rail.

Special Prices.—The price fixing program adopted is expected to take care of all normal mining conditions and to permit the operation, with a reasonble profit, of all mines necessary to the country under war conditions. There are cases, however, of old established mines which are producing coal of a quality specially suited to certain processes or requirements, which coal, while produced at a cost materially above the regional "bulk line," is necessary and has always commanded a special price. In these cases, a higher price, sufficient to permit operation, is usually granted. Also, in some cases, groups of small mines, not required to report, are found to be serving certain communities at prices below other coal available, considering the transportation charges, but with costs above the regional "bulk line." These also receive special prices. In general, it is the policy of the Fuel Administration to encourage the operators to produce all coal needed and to place restrictions only on coal mined under conditions notably uneconomic.

Effect of Short Time.—While it is a syllogism in mining regions that "short time means increased costs," but little actual information as to the quantitative effect of lost time on the cost of coal mining is available. In the discussion as to the advantages or disadvantages of an even car supply to all mines, as compared with 100 per cent. supply to some and the remainder to the others, it developed upon the committee to determine, at least approximately, the effect of lost time on mining cost.

Reports from 73 Operators Were Analyzed

Fortunately reports were available from 73 operators in the New River district of West Virginia, which had been made out and submitted by an eminent firm of expert accountants for each month of the year 1917. Each of these was carefully analyzed, and the percentage increase of cost for each of the 830 observations thus obtained was platted; weighted averages were then taken at each 2.5 per cent. from 70 to 100 per cent. working time, and for each 5 per cent. below 80 per cent. The result of this study is submitted on diagram No. 6 which has been checked by numerous observations from practically every field, and has been found, within reasonable limits, to be correct. This diagram can be and has been used in reducing to normal cost the reported costs of collieries shut down during parts of months.

Anthracite prices were fixed by the President on Aug. 23, 1917, and have not since been revised. The latter is now a subject of intensive study, and it is expected that after sufficient data have been accumulated a revision and scientific price fixing will be attempted.

The problem of anthracite price fixing presents all the difficulties encountered in the bituminous fields, complicated beyond measure by the varying percentages of sizes produced by different mines in the same region, and the still more widely varying percentage of sizes produced by the different regions.

It should be generally known that the United States Fuel Administration exists only for war conditions. It expires by limitation of the Lever Act. The Administration is endeavoring most earnestly to give both to the miners and to the consuming public a fair deal and no favor. It has accomplished incredible results in conservation of fuel and stimulation of output, but such results have only been possible by the earnest, whole hearted, and patriotic support freely given by operators, miners, and by the consuming public.

DEPARTMENT OF HUMAN INTEREST

Using Posters to Boost Coal Tonnage

To stimulate the mine workers to produce a greater tonnage the anthracite producing companies have had recourse to big poster cards 20 x 30 in., printed with scarehead type and placed in the most conspicuous places in and about the mines, so that mine workers will not fail to see and read them. A poster put up by the Lehigh Coal and Navigation Co. on all its properties reads as follows:

Hit the Hun

Our mine output for
August, 1918, was 370,000 tons
August, 1917, was 392,000 tons

A loss
amounting to 22,000 tons

1 ton of coal makes 40
3-in. shells. In August

We lost 880,000 Shells

To back up our boys
"over there"

Let us make it up in September

A record tonnage means
a wallop at the Kaiser

Speed up September

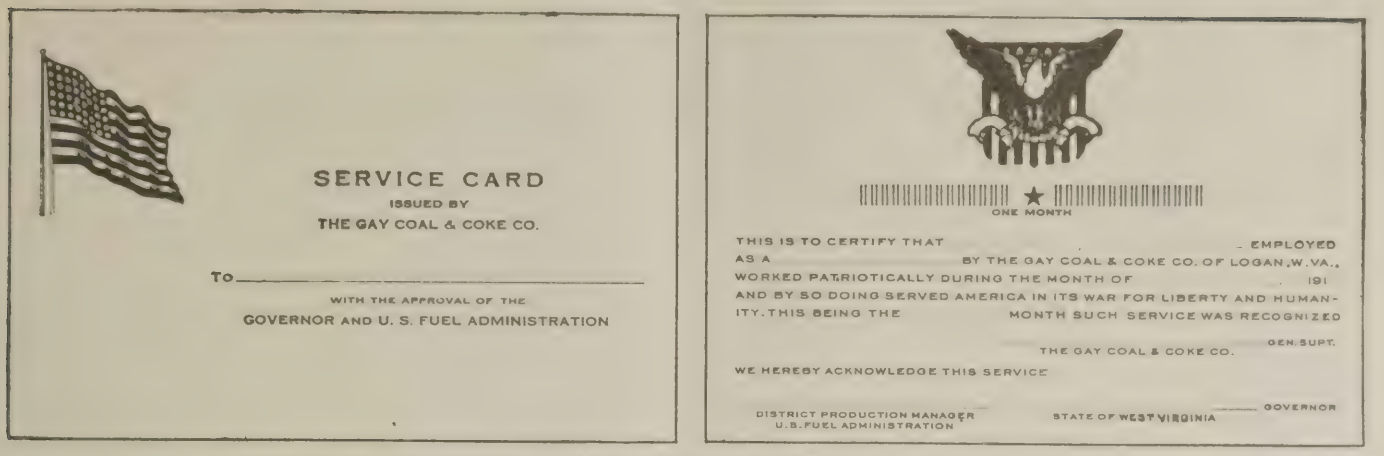
L. C. & N. Co.

Other authorities declare that one ton of coal will manufacture only 27 three-inch shells but, more or less, the figure is startling whether you write it as 880,000 or 594,000, remembering as we must that a shell might well destroy a man who living might take the life of one of our boys "over there." These poster cards are well calculated to keep ever before the mine worker the tremendous importance of the work which lies before him and the part he has in the winning of the war.

All Kinds of Patriotic Work at Gary

The annual inspection of the gardens and yards of the employees of the United States Coal and Coke Co. at Gary, McDowell County, West Virginia, was made July 29, 30 and 31. The judges were Professor W. Paddock, head of the Horticulture Department, Ohio State University, Professor Dee Crane, representing West Virginia University, and Bert E. Sayre, representing the West Virginia Department of Agriculture. The judges found the gardens as a whole very productive. Many of these gardens had been planted under difficult circumstances, some being on ground that had been filled around newly constructed houses.

At one plant the garden of an Italian coal loader was found on an almost perpendicular hillside, the ground having been terraced laboriously as is customary in such cases in Europe. This man had about 25 varieties of vegetables in his garden, and yet he had worked every day at his occupation of coal loading. In another garden they found 600 newly planted grape vines methodically set out and properly staked. Interspersed between the vines were planted tomatoes, cabbage and other vegetables. At some of the plants all the yards had been used for gardens. The judges estimated that the gardens at the plants of the United States Coal and Coke Co. would bring at current market prices between $100,000 and $150,000.



The employees of the United States Coal and Coke Co. have shown their patriotism in every call the government has made upon them: Red Cross work, Liberty Bonds and Y. M. C. A. work; and this inspection shows that they have likewise done their part in raising food supplies.

Reward for Patriotism in West Virginia

The Gay Coal and Coke Co., at Logan, W. Va., is issuing a four-page "Semi-Monthly Bulletin" for its employees. It is a pleasure to quote the remarks on "Service Cards" in its first issue, which appeared Aug. 31, 1918.

"Employees who render patriotic service by working full time each month will be awarded by the company with a service card certifying to that fact. This card will be approved by the general superintendent of the company and signed by Governor Cornwell and by the production manager of the United States Fuel Administration. Cards will be issued each month. Your first month's card will bear one star, the second month two stars and the third month three stars. The service, however, must be rendered in consecutive months; that is, to secure a card with three stars it will be necessary to have worked three months full time in succession.

"If an employee cannot work every day it does not mean that he will be deprived of a card. For instance: Should you desire to lay off a day or two for personal reasons, secure permission from your foreman or boss,

ENVELOPE AND SERVICE CARD ISSUED BY THE GAY COAL AND COKE CO.

who will issue you a written excuse. In doing this you will enable him to find someone to take your place without the production of the mine being curtailed. Should no cars be received and you report for duty and cannot work, it will be assumed, in keeping the record of your service, that you worked a full day. If you are compelled to lose time through reason of any fault not your own (that is to say, through any fault of the company in not furnishing you with work) you will be considered as having worked that day.

"In case of sickness, the company doctor or other practicing physician will furnish an excuse in writing, a copy being retained by the foreman or boss issuing it and a second copy being filed in the payroll office. This system with your own help will enable you to have a perfectly clean record each month. The value of these service cards cannot well be overestimated.

"Should you desire to leave the service of the company and apply to someone else for employment you could show a recommendation of weight and value. Should one of your friends come back from 'Over There' you could show him with pride that while he was doing his part you were doing yours. On the last page of *The Bulletin* issued for the first half of each month will appear the names of those who are entitled to service cards for the preceding month."

Some important directions to be observed after an explosion are as follows: Keep all air compressors working; if they are not working, start them, so that fresh air can be forced into the mine workings. Shut off all electric power entering the mine, unless this power is on a separate circuit entering a shaft or borehole to drive a ventilating fan. Do this in order to prevent any live men or the men who may come in contact with the electric wire from being electrocuted, and to prevent a fire or explosion through the short circuiting of any wires that may have been blown down.—*Rescue and Recovery Operations in Mines.*

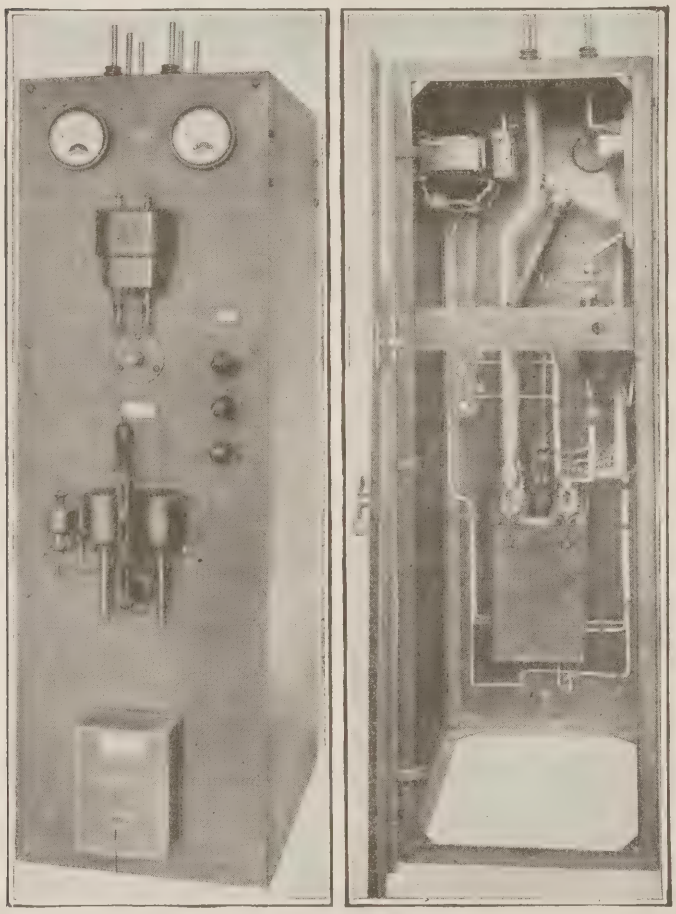
STICK TO YOUR JOB

Written expressly for Coal Age

By RUFUS T. STROHM

You watched your pals as they marched away
To the snare-drum's martial rattle;
Your heart grew sick at the thought that they
Would strive in the heat of battle
While you held off, like a yellow cur,
Apart from the noise and bustle;
But such a thought is a baseless slur—
Stick close to your job, and hustle!

Let others dare where the star-shell's flare
Turns night into daylight glowing;
You're needed here, if the vast affair
Of war is to keep a-going.
The force that wins to the long-sought goal
Depends on the iron muscle
Of those who delve for the nation's coal,
So stay on the job, and hustle!



Shoot down the coal in a black cascade,
For that is the kind of shooting
That pays old Fritz for his every raid,
His lies and his savage looting;
And don't lament that you're left behind,
Denied a part in the tussle,
For winning hangs on the coal that's mined,
So cling to your job, and hustle!

Since coal is the mainspring of the war,
And you are a loyal miner,
Advance the cause we are fighting for,
Than which there is nothing finer;
Forget your dream of a far-off coast,
And death where the wheat-stalks rustle,
And give your help where it counts for most—
Stay right on the job and hustle!

New Apparatus and Equipment

Steel Switching Cabinet

The steel switching cabinet shown in the accompanying illustration is a unit made for single-, quarter- and three-phase circuits in capacities up to 300 amp. at 15,000 volts, and 800 amp. at 600 volts. All current-carrying parts are inclosed, and provision is made for bringing the leads out at top, bottom or sides of the unit. The cabinet consists primarily of instrument transformers, oil circuit breakers and disconnecting switches inclosed in a sheet-steel compartment with instruments, operating levers, etc., mounted on the sheet-steel front.

CLOSED AND OPEN VIEWS OF STEEL SWITCHING CABINET

The main switching apparatus consists of a standard switchboard-type oil circuit breaker operated in the ordinary manner. The oil circuit breaker is mechanically interlocked with the disconnecting switch so that this switch cannot be opened or closed while the oil circuit breaker is closed. The disconnecting switch is operated by means of a special handle or wrench from the front of the panel, and is so interlocked that the rear door cannot be opened while the switch is closed, nor can the switch be closed while the door is open.

This apparatus has been designed for use as distribution and tying in switches, as control switches for induction and synchronous motors, etc. It is usually mounted as a single unit but may be installed in groups if desired. When made with a drip roof the switching cabinet is particularly adapted to use in mines or other damp places. It can be made nearly water, gas and dust proof. It can also be used to control large motors in steel and cement mills, pumping plants, etc., where conditions often exist which cause the switching apparatus to become damaged or to be put out of service by dust, moisture and chains from traveling cranes.

Conveyors Replace Common Labor

Nowhere in the industrial fabric has the disturbance brought on by war conditions been more keenly felt than in the unskilled labor market—among the shovelers, lifters and movers of goods and materials. Perhaps because this type of labor had always been plentiful and relatively cheap there had been, before the war, less application of machinery to such purposes than in almost any other field.

Ore docks, coal docks, grain elevators and some large plants were equipped with complete and well arranged conveyor systems. But unless large quantities of material were handled in a highly organized way, it was the custom to depend on human labor using primitive equipment. Retail coal yards, factory power plants and construction jobs were examples of undertakings where it would long ago have been practical to install mechanical handling of materials, and where human labor was usually exclusively depended upon.

War conditions undermined old methods from two directions. Transportation became uncertain and made it essential to receive material in the largest possible quantities whenever transportation was available and to store it until it could be used. It was no longer possible to depend on shipments arriving at the plant in such regular sequence that coal or other materials could be unloaded from the cars for immediate use.

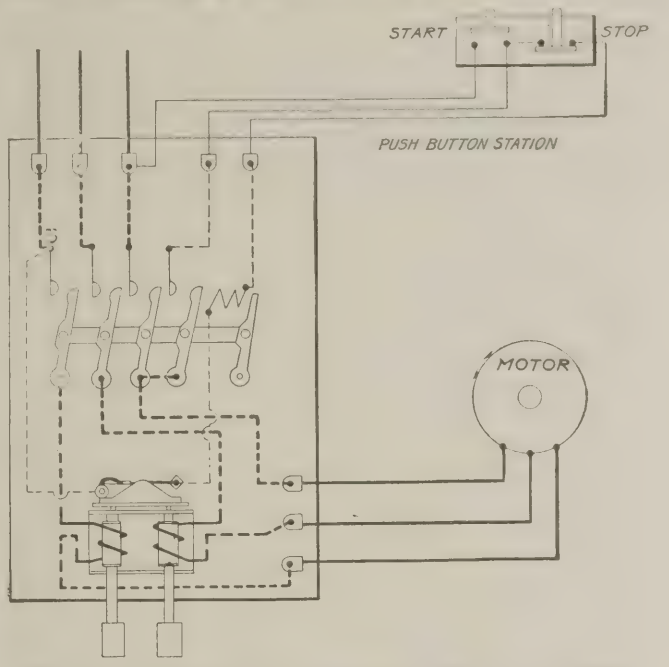
This situation aroused more interest in light, portable material-handling machines than ever had been felt before. It became an established principle with many companies not only to replace labor by machinery whenever the machine could do the work cheaper, but to give preference to the machine if the costs were the same or even slightly higher.

Conditions were ripe for the rapid application of light, portable conveyors to all sorts of handling problems. A grade of engineering skill and manufacturing ability was attracted to their production that had not previously been devoted to them. Light, strong, well-designed portable conveyors, economical of power, easily moved about and set up, made their appearance. These are adapted to handling coal, sand, gravel, ashes, salt chemicals, package goods, brick and stone.

They were designed and built in standardized sections that could be assembled in units of any length to meet varying requirements. This made it practical to carry at factory for prompt shipment a large stock—and held down the investment tied up in such a stock to reasonable proportions.

Such portable belt conveyors elevate as well as move material and so have made it possible to use more fully the storage space available. Without additional cost material can be piled to the top of a warehouse or a coal shed, while on the open ground higher and more compact piling of material is possible. Additional construction of storage buildings can in this way often be avoided.

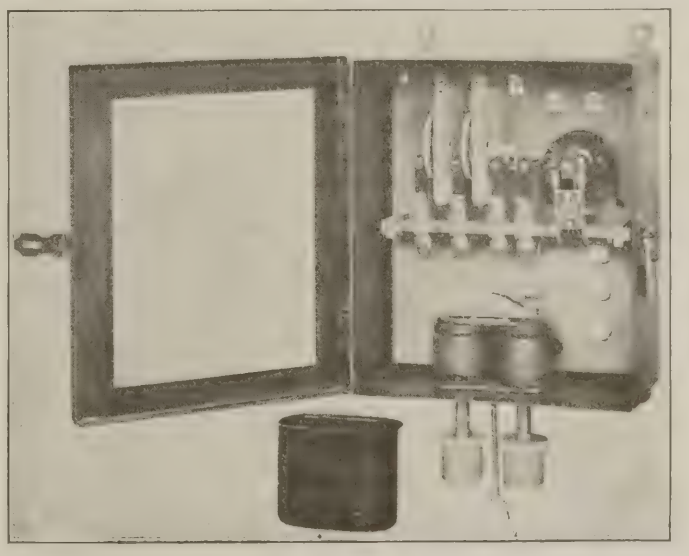
In the service of the Western United Gas and Electric Co. at its plant in Joliet, Ill., two portable belt conveyors made by the Barber-Greene Company, of Aurora, Ill., are operated in series in loading coke into railway cars. These cars are loaded in from two to four hours, according to size and type, with less than half the labor that was previously required to load them in from 7 to 10 hours. The saving in cost is about 50 per cent.



VIEW OF LIGHT CONVEYOR AT WORK

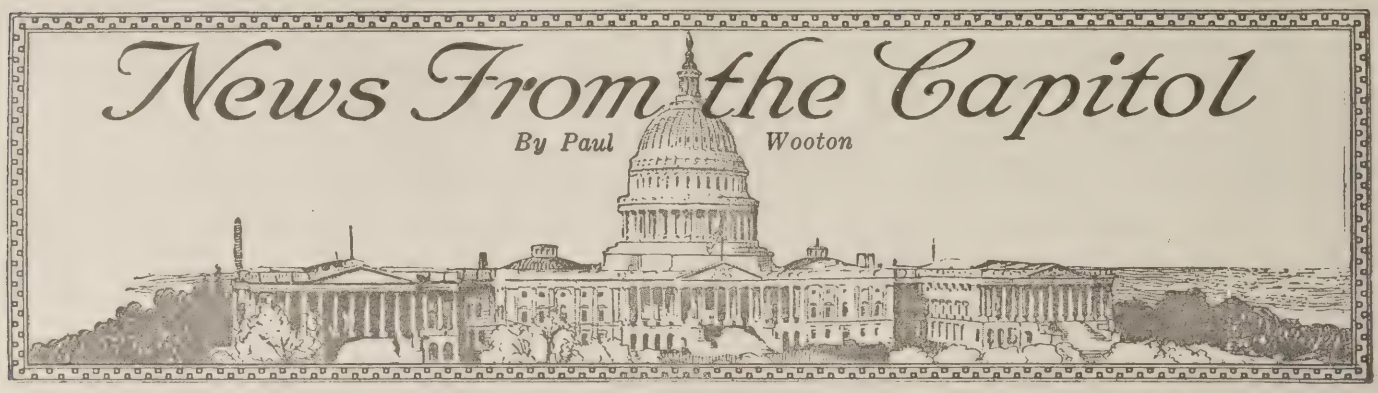
Several types of conveyors have been developed to meet different requirements by the Barber-Greene Company. For elevating at angles under 25 deg. a plain belt is employed. For angles of 30 to 35 deg. a belt equipped with steel flights is provided to prevent the material from slipping down the grade. For chemicals that will corrode metal, conveyors of similar design are provided with wooden frames. The conveyors are made portable by mounting them on a wheeled truck or suspending them from a trolley attached to an overhead steel cable.

A wide variety of applications have been worked out since these machines went into use—many of them unforeseen until they were discovered in practical operation. They unload cars into piles, into storage sheds, into wagons or motor trucks. They load cars from trucks or wagons, storage piles or sheds. Where the carry is long two or more conveyors can be worked in combination—sometimes with a chute between them.



Remote-Control Starters

There has always been a demand for a device for starting small induction motors from remote points by throwing them directly across the line. The General Electric Co. has recently developed and placed upon the market such a starter, known as the CR-7006 remote-control switch, arranged for push-button control. This starter is applicable for use with motors up to and including 5 hp., 110 volts, and 7½ hp., 220, 440 and 550 volts. In addition to its starting function the device provides protection against undervoltage and overload. The device consists of a 25-amp., three-pole contactor with two inverse, time-limit, gravity-reset, overload relays mounted on a slate base totally inclosed in a strong sheet-iron case. A small "start and stop" push-button station is used as a remote-control switch. Completion



WIRING DIAGRAM OF REMOTE-CONTROL STARTER

of the starting circuit, by pressing the "start" button, energizes the coil of the magnetically operated switch, closing the contacts, which throws the motor directly on the line. Interruption of the circuit or a radical decrease in voltage permits the contacts to reopen by gravity, thus stopping the motor, which cannot start again until the "start" button is pressed.

REMOTE-CONTROL SWITCH OPERATED BY PUSH BUTTON

The overload relays can be adjusted for various values ranging from normal up to 50 per cent. above normal. They can also be adjusted over a wide range of time values. The relay trips automatically and resets by gravity. The cover of the inclosing case is furnished with a hasp so that if desired it can be locked in a closed position by a padlock.

New Prices Authorized for Certain Mines

New prices have been authorized for the Montevallo Mining Co., of Alabama, as follows: Run-of-mine, $3.65; prepared sizes, $3.90; slack or screenings, $3.15.

New prices have been authorized for coal produced by the Loony Creek Coal Co. and by the Reliance Coal and Coke Co., each of Kentucky, as follows: Run-of-mine, $2.55; prepared sizes, $2.80; slack or screenings, $2.30.

Owing to the unusual expense required in the stripping operation of the Graff Mining Co. in Westmoreland County, Pennsylvania, the Fuel Administration has allowed a price of $2.95 for run-of-mine, prepared sizes, or screenings. No addition is to be made for the wage agreement.

New Prices for Colorado Gas Coke

New prices for gas coke in Colorado have been established as follows: Run-of-retort, $5.50; run-of-retort, screened, over ¾ in., $6: prepared sizes above ¾ in., $6.50; prepared sizes below ¾ in., $4.50. The price at Colorado Springs may be 50c. in excess of those mentioned.

Stops Issuance of Distributors Licenses

An increase of 200 per cent. in the number of coal and coke distributors during the past seven months has caused the Fuel Administration to suspend the issuance of licenses pending an investigation. Some are of the opinion that advantage is being taken of the purchasing agent's commission and distributors are embarking in the business to contribute neither skill, experience nor anything else of value.

To Study Cargo and Coal Handling Methods at American Ports

New cargo and bunker coal handling machinery or new adaptations of the machinery now being used at the ports is considered by the Port and Harbor Facilities Commission the most likely means of cutting down a ship's "turnover." The active ports of the Old World have developed many of these devices, some of which are of American invention, and it is due to them that the capacity of the port is increased and cargoes handled quickly and cheaply.

"We want to make our ports as efficient as any in the world," says a statement issued by the committee. "We want to benefit by the experience abroad. We want to bring the standard of efficiency for machinery for handling general cargo and bunker coal up to the standard reached by the ore and coal handling machinery of the Great Lakes and elsewhere in the United States which is of American invention and admittedly the most efficient in the world.

"American manufacturers have been invited by the Port and Harbor Facilities Commission to make a careful study of our entire port situation to the end that possible new and ingenious methods of handling cargo and coal may be developed in conjunction with the best arrangement of piers, warehouses and other terminal facilities.

"Improvements, particularly in machinery, are desired now not only to expedite the movements of supplies to our armies in France, but also to have our mercantile marine ready to meet the keen competition that will follow after the war."

Price Fixed on Reclaimed Coke

A price of $5.50 has been authorized for mixed sizes of screened and cleaned beehive or byproduct coke reclaimed at the point of production from accumulated breeze piles. Such business, however, must be conducted under permit.

Production Quotas Now Being Assigned

Actual assignment of production quotas has been begun by the director of production for the Fuel Administration. Eventually each mine in the United States will have a rating and, as Dr. Garfield puts it, "individual responsibility." The enterprise of James S. Amend, the production manager for the Greensburg-Westmoreland district, is credited for making possible thus early the assignment of quotas in that district. When the rating of the mine has been established, the following letter from the director of production is sent to the operator:

After careful investigation it has been decided that your mine can produce at least ——— tons per day, and that tonnage has been allotted to you. It will be necessary for you to produce an average daily tonnage of ——— in order that you may contribute your fair share of the total coal tonnage needed by the United States Government in carrying out its war program.

The total coal requirements are definitely known and this has been allotted to the various producing districts and to each mine in each district. From this you will see that if the total amount is to be produced it is essential that no mine fail to meet that part of the Government requirement allotted to it. You will please make this situation known to your operating officers and to the mine workers in your employ, telling them that the United States Government looks to them in full confidence that they will accept the allotment of ——— tons per day as their fair share and

will cheerfully see to it that at least that amount is produced without fail.

Unless a sufficient tonnage of coal is produced it will be impossible for the United States Government to furnish to General Pershing material in sufficient quantities to enable him to carry on a successful campaign against our enemies with the smallest possible loss of life and labor. I have no doubt that every man and boy in your employ will gladly do his part and will rejoice in having this opportunity to contribute toward winning the great war which is being waged for democracy.

Plans to Increase Coke Production

In response to an appeal from the War Industries Board for more coke, the Fuel Administration is launching a campaign looking to the increase of that important material in the making of steel. Steel requirements are millions of tons above the present output. The limiting factor is pig iron, and in the making of pig iron coke is the essential holding back output.

A hasty survey of the situation shows a great deal of idleness among coke workers. A material increase in coke production can be obtained if the required labor can be secured. Comparatively little attention has been given the matter of idleness among coke workers. If the methods now being used so successfully among coal miners are applied to coke workers, it is believed that a marked increase in coke production will result. James B. Neale, who is in charge of production for the Fuel Administration, is directing the new campaign.

Will Rehabilitate French Coal Mines

Much of the material which will be necessary for rehabilitating the coal mines in the Lens region of France will be supplied by the United States. Plans to this end were almost perfected more than a year ago when the recovery of the coal fields seemed imminent. Officials of the War Industries Board, the Fuel Administration, the Bureau of Mines and the French War Mission already are busy on the problems involved.

More Coal Cars Being Loaded This Year

From Jan. 1, 1918, to Sept. 28 there had been loaded 641,761 cars of coal more than in the same period of 1917, according to the Railroad Administration. A summary of the loading of coal for the week ended Sept. 21 is as follows:

	1918	1917
Total cars bituminous	219,925	182,565
Total cars anthracite	36,859	37,294
Total cars lignite	4,056	3,379
Grand total cars all coal	260,840	223,238

A summary of reports for the week ended September 28, 1918, based on actual reports from most roads, but with the results of some roads estimated, follows:

	1918	1917
Total cars bituminous	226,238	191,185
Total cars anthracite	40,524	42,008
Total cars lignite	4,016	3,647
Grand total cars all coal	270,778	236,840

A drive is being made by the Forest Service, now that crops are out of the way, to stimulate the cutting of wood by farmers. It is pointed out that the heating value of one standard cord of well seasoned hard wood is equal to a ton of anthracite coal.

Summary of Traffic Conditions

Reporting to the Railroad Administration, the Fuel Administration summarizes traffic conditions as follows: "Car supply uniformly good in the East. Some accumulation on Baltimore & Ohio and need of power on Chesapeake & Ohio.

"Tidewater—Vessel supply ample.

"Lake Situation—Good, ample supply of coal at docks and dumping increased.

"Southern Region—Some car shortage in Birmingham district and in southwest Virginia.

"Coke—Car supply good."

Coal and Coke in 1917

The production of bituminous coal in 1917 was 551,790,563 net tons, an increase over 1916 of 49,270,881 tons, or nearly 10 per cent., according to C. E. Lesher, of the United States Geological Survey, Department of the Interior.

The production of Pennsylvania anthracite in 1917 established a new high record of 99,611,811 net tons (88,939,117 gross tons), exceeding that in 1916 by 12,033,318 net tons, or nearly 14 per cent., and surpassing the previous record of 91,524,922 net tons in 1913. With the exception of West Virginia all the large coal-producing states recorded increases, the only decreases having been in West Virginia (0.02 per cent.), Oregon, South Dakota and Georgia.

The production of coke in 1917 was 55,606,828 tons, an increase compared with 1916 of 1,073,243 tons, or 2.0 per cent. The output of byproduct coke increased from 19,069,361 tons in 1916 to 22,439,280 tons in 1917 and represented 40.4 per cent. of the total in 1917 against 35 per cent. of the total in 1916. The production of beehive coke decreased from 35,464,224 tons in 1916 to 33,067,548 tons in 1917. The number of active byproduct ovens increased from 6607 in 1916 to 7298 in 1917, and of beehive ovens from 65,605 to 68,687, but the irregularity of operation of beehive ovens in 1917, due principally to lack of railroad cars, reduced the average production per oven.

The number of men engaged in producing bituminous coal increased from 561,102 in 1916 to 603,143 in 1917, and the number producing anthracite decreased from 159,869 in 1916 to 154,174 in 1917. However, the number of men employed underground in the production of bituminous coal increased from 474,244 in 1916 to 498,185 in 1917, a gain of but 5 per cent. compared with a gain of 20.8 per cent. in surface employees.

In the anthracite regions the number of underground employees decreased 5.8 per cent., but the surface employees increased 2.4 per cent. In both branches of the coal-mining industry there was a relatively large gain in the number of men employed on the surface, which is significant when it is realized that it is the underground worker who actually produces the coal and who is the more skilled workman.

The average number of days worked in both bituminous coal fields and anthracite mines was the highest recorded—243 in the bituminous field and 285 in the anthracite.

A bond slacker is the Kaiser's backer.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The mine workers of the anthracite region were promised on Oct. 5 that an announcement would be made Oct. 15 relative to a change in scale. However, on going to press no such notice had been made. It is understood that there will be an increase, the amount of which will be announced Oct. 17, the date of this issue. The increase will bring the anthracite wage scale closer to the scale of the bituminous region. This gives substantial justice at this time as between the two regions, but it will give the anthracite worker by far the greater earning power, just as soon as the bituminous mines drop back, after the war, to their old-time desultory schedule of operation.

> One of the things that my father used to teach me when I was a boy was that it was not advisable to be honest solely because honesty was the best policy, but that it was advisable to be honest because honesty is right. And so it is with contract obligations, it is advisable to live up to your contracts not so much because you benefit from living up to them, although that has been the result, as it is essential that you should live up to them because living up to them is right.—*Secretary of Labor Wilson in reference to the wage increase asked in anthracite region.*

The anthracite region works steadily now and has done so for years. Everything, except perhaps the introduction of byproduct coal and carbocoal, seems to assure the continuance of steady work in the anthracite region. In fact it is likely to become increasingly steady as the years pass. Consequently the wage scale in the anthracite region, though based on the bituminous region and the short time its men work, will afford higher monthly wages than the wage scale of the bituminous region.

Yet it is likely that few will move into the anthracite mines. The evil apprenticeship rule keeps away the men from other sections. Many of the miners in the anthracite regions are foreigners and of peasant origin. No American wants to work as a laborer for such men, doing all the hard work and carrying off only a modicum of the pay. In fact the situation in the anthracite region is unbearably un-American and so long as the condition continues only immigrants will be found willing to fit themselves into it.

The mine workers in the anthracite region have shown that the increase in wage is not really needed by all of them for the maintenance of comfortable living. Of late it has been hard to get some of them to work steadily. At the plant of the Lytle Coal Co., near Minersville, the record of one month showed a loss of over 400 shifts. Most of these were lost by certain men who were absent from work day after day.

The complaint regarding the low wage is chiefly from the day workers who are not by any means as generously dealt with as the contract miners. The conference which will decide on the scale has been in session since Oct. 3. The union decided to ask for the increase on Aug. 16 and presented their request to Mr. Garfield on Aug. 22.

In Dubois, a leading town in the Clearfield district, a meeting was held Oct. 4 at which brewers and wholesale liquor dealers of the district promised the representatives of the Fuel Administration, there present, that they would not ship liquor into dry areas. The liquor dealers and brewers agreed to sell only to those persons who were known to them. The speakeasy evil is to be broken up. The day before the conference, Oct. 2, the retail liquor dealers made a promise similar to the pledge made by the wholesalers and brewers. The Fuel Administration has determined to try and put restrictions such as these in operation all over the United States and thus cure a loss of production from inebriety which is said to amount to from 5 to 9 per cent. of the whole production.

In the Butler-Mercer field the men have shown their loyalty, not only by an increased production but by undertaking to work full time. F. B. Reimann, production manager for his district, which includes all northwestern Pennsylvania, reports that at a mass meeting of the mine workers of Zenith mines Nos. 1 and 2, under the presidency of William M. Kay, the following resolution was passed:

"In response to President Wilson's appeal to the American miners to do everything in their power to increase the production of coal: We, the mine workers of Zenith mines No. 1 and No. 2 and of the new Victoria mine, in mass meeting assembled this 18th day of September, 1918, near Butler, Penn., do hereby pledge ourselves to work 50 full hours every week until the end of the war, unless prevented by causes beyond our control, and we hereby call on our fellow mine workers in the Butler-Mercer field to coöperate in making the production of this field 100 per cent."

In the Pittsburgh district Richard W. Gardiner, manager of production, is troubled by the fact that several local draft boards are exceeding their authority by placing miners in Class 1, thus causing them to be subject to immediate draft. He has been quite active also in his endeavor to prevent the miners from laying off for midday parades such as are being held on behalf of the Fourth Liberty Loan. These demonstrations of patriotic fervor should, he says, be delayed till 4 o'clock, at least, so that a full day's tonnage may be obtained, for unless we fulfill our duties as citizens we are not entitled to celebrate what we have done.

According to John Moore, the president of the United Mine Workers in Ohio, 100 out of 600 local unions report that the men comprising them bought about $726,000 worth of Third Liberty Bonds and had early in October purchased $432,319 worth of War Savings Stamps.

At Logan, W. Va., medals are being distributed to "industrial soldiers." A. C. Clapperton, general superintendent of the Amherst Coal Co. at Amherstdale, wears one himself and says that 416 of his mine workers will each receive one also. A bronze bar will indicate that the worker has done his full share of work for one month; a silver bar will attest the same for the second month; a bronze bar will be added to show the same service during the third month, and, after the fourth month of faithful service, a silver bar will be added and so on. Thus a worker will be readily recognized as a "steady" if the bronze and silver bars appear in right number and in regular alternation.

During the first month of this arrangement only 4 men in the employ of the Amherst Coal Co. put in less than 38 hours a week. The car supply was regular, so this result was made easy. The company has a storage arrangement, a Brown hoist loading the coal into railroad cars as soon as they arrive. A car can be filled in 22 min. Storage is made easy by reason of a convenient rocky ledge over which the coal can be dumped. As the coal contains little sulphur, and apparently that sulphur not of the kind which starts fires spontaneously, there has been no trouble from the firing of the coal piles.

The medals cost the company only 38c. each but the cost of the bars should be added. The Amherstdale mine workers find in the company a liberal landlord and a generous coal sales agent. Coal is sold the men at $1 a load, the company losing from 50c. to 75c. a ton by each sale. The houses rent for $10 a month though similar houses in Logan would readily bring $25 to $40 a month.

The Low Ash Coal Co. of Crown, Logan County, West Virginia, has a "black diamond" who loads 26 tons of coal every day the mine is operated. Last June the mine worked only 19 days, and this man, John Howard, loaded 525 tons of coal or 27.63 tons per day. On one of these 19 days the superintendent was afraid that he could not load all the cars furnished and Howard straightened himself up and put 50 tons on the cars that day. His earnings

JOHN HOWARD, WHO LOADED 50 TONS IN ONE DAY

are going into Liberty Bonds. John Howard is a "regular fellow," be it known; he drives a Ford.

The Pocahontas district has been asked for 14 per cent. more coal monthly. It is called upon to deliver 2,000,000 tons during the month of October. Such a large tonnage has never before been mined in this field. At Glen Jean, Fayette County, on Sunday, Oct. 6, a large meeting of miners, foremen, superintendents, other mine officials and operators was held under the leadership of James B. Neale, the Director of Coal Production for the United States Fuel Administration. There were 10,000 persons present from all over the New River field. James B. Neale spoke, also P. B. Noyes, the Director of Coal Conservation, Governor John J. Cornwell, Trooper Scott, Sergeant Brown and Lieutenant Nelidow.

In Kentucky operators are complaining that the boards are exempting only those men who are rated as skilled laborers—motormen, machine men, electricians and the like. The operators have made an appeal urging that coal loaders, and men who shoot the coal, are, in a degree, skilled and should be granted deferred classification.

The Kentucky draft boards find that a large proportion of the population would normally be exempt and consequently are disposed to turn a deaf ear to the requests for exemption unless the men seeking such a privilege are more than usually essential and have a reputation for steady work and large production. The associations of companies represented at the meeting which made the protest to Major H. B. Rhodes, of Frankfort, Ky., and the State Draft Advisory Board, were the South Appalachian, the Harlan coal operators, the Tug River operators, the Northeastern Kentucky Association and the Harold coal operators. These companies mine the best coal of Kentucky, much of which is of transport and byproduct-oven quality. It is extremely essential that these producers be not unduly interfered with, as their product is essential for the most vital of war uses.

Spanish influenza has invaded many of the coal fields thus reducing production in the Cumberland-Piedmont districts of Maryland and in Virginia and West Virginia, some mines being wholly closed and some operated only part time. In these sections the production is estimated at 50 per cent. of normal owing to the action of this disease. In Tennessee, Kentucky and Alabama the week's tonnage ranged from 15 to 50 per cent. of normal.

Reports from Altoona were to the effect that the tonnage in the Central Pennsylvania district fell off 70,000 tons or more than 5 per cent. of maximum output. Even at that the production was considerably larger than last year. Virginia has sent Dr. Paul B. Barringer, who was for many years with the University of Virginia to Bluefield, and he will visit all the mines in Virginia adjacent to Bluefield. Governor Cornwell, of West Virginia, has sent a representative to confer with him.

Doctor Barringer found 18 cases at Pocahontas, and reports arrived from the Richlands district saying that at least one-third of the miners were ill with the disease. One death had resulted. Other cases were reported in the neighborhood of Honaker.

Unrest in Canadian Coal Fields

The miners in district No. 18 of the United Mine Workers of America are extremely restless and seem to want a strike regardless of cause. The sliding scale has removed the old complaint about the cost of living, for the wages now rise with the increasing commodity costs. But it is still possible to strike because of an alleged unsafe condition of the mines, and 1300 miners at Fernie, Michel and Coal Creek are doing this; and they propose to get out the rest of the district if they can.

William Sloan, the Minister of Mines, offered to appoint immediately, under Section 73 of the Coal Mines Regulation Act, a commission composed of three members, one chosen by the miners, one by the operators and a third by the lieutenant-governor in council on the recommendation of the Minister of Mines. This commission, if the proposal had been accepted, would have taken evidence at once relative to the mining dangers at Michel and Coal Creek for which a remedy is still to be sought. What recommendations they would have made would have been binding on everyone.

This constituted the first proposal. The second was that the Minister of Mines pledge himself to "introduce at the next session an amendment to the Coal Mines Regulation Act calling for the production of coal in only one shift in every 24 hours throughout the Province of British Columbia, except in case or cases of national emergency." The amendment was to become effective within one year after the conclusion of the war.

The proposal was telegraphed to Fernie and was voted on unfavorably by the representatives in secret ballot. The company was perfectly willing to accept the suggestion submitted, but as the men turned it down and continued on strike the matter continued just where it was.

Thomas Biggs and E. E. Brown, district president and secretary respectively, held a conference on Sept. 21 with the provincial cabinet. They agreed to recommend that the mine workers return to work for 30 days on the single-shift basis, while the questions at issue were decided. Even this failed to satisfy the men, and the strike continued. The Crow's Nest Pass Coal Co. assented to the arrangement, as it has to every other change suggested.

There seems to be nothing of a reactionary character about W. R. Wilson, the general manager. Working conditions have been improved, as the men were good enough to admit. Chemical analyses of the air made by the Burrell indicator show a reduction in the percentage of methane of from 25 to 75 per cent. These Burrell indicators have been introduced as a means of more careful determination of the methane content. The company has agreed not to extract more than 15 per cent. of the coal at first working. The coal dust has not only been sprinkled with water, but also with fine flue dust. Electric safety lamps have been introduced in place of flame safety lamps.

The Province of British Columbia also has been active in meeting the problem. It is preparing to adopt George Rice's recommendation for the appointment of a permanent commission to investigate the "bumps" in the mines.

The miners finally offered to go back to work if the principle of the single-shift were accepted for all mines, if places were found at once for as many as possible on single shift and if places were provided for all within 30 days. They did not want the matter arbitrated. On Sept. 25 they declared that if their offer was not accepted by the following day they would order out the firemen, pumpmen and fanmen, making the possibility of an early return to work impossible.

Mr. Sloan was not prepared to require that all mines be run single shift. He made the suggestion that No. 1 mine, Coal Creek, where most of the bumps have occurred, be given separate treatment. He said it might be closed down or worked 8 hours in every 24 hours.

Director Armstrong Concedes Everything

The Dominion Director of Coal Operations, W. H. Armstrong, finally took up the dispute and used all the wide powers which were given him when the strike was at its height a year ago. The mine workers expected a great deal from him, because when he was appointed he made a wage scale full of concessions. The mine workers like a potentate of this kind who can wind up their disputes by conceding all that they ask. W. H. Armstrong's action was to issue the following document on Sept. 27, 1918:

"A request has been received from miners employed at the mines of the Crow's Nest Pass Coal Co. Ltd., at Coal Creek and Michel, asking the adoption of a single shift in all the mines instead of a double shift as at present. This request is based on the allegation of the men that there is a dangerous condition of the mines due to working double shift.

"The question of the safety of the above mentioned mines is one that comes under the regulations of the Coal Mines Regulation Act of British Columbia and therefore comes within the jurisdiction of the Department of Mines of that province and not under the jurisdiction of the Director of Coal Operations.

"The issue as to whether or not the operation of those mines would be more dangerous on a double shift than on a single shift is one upon which the representatives of the men and the company disagree.

"However, in view of the difference of opinion which has developed I hereby instruct the Crow's Nest Pass Coal Co., Ltd., to install a single-shift system at their mines and will request the Minister of Mines of British Columbia to appoint a Royal Commission as proposed by him to determine the question at issue, the Commission to report without delay when the matter under dispute will again be reviewed.

"It is further understood that the single-shift system does not apply to development places nor to necessary repairs in the mines.

"By virtue of the authority vested in me by order of the Committee of the Privy Council, passed under the provisions of the War Measures Act of Canada, 1914, I hereby direct the foregoing conditions shall be in force and effect at the mines of the Crow's Nest Pass Coal Co., Ltd., until further notice."

But Everything Appears Not To Be Enough

But this decision of W. H. Armstrong was not sufficiently subservient to please the mine workers, who were utterly irresponsive to every appeal and had cast off the leadership of their union officials. Apparently they did not want to have any commission appointed to consider their demands, because they realized that they might not win out when the matter was considered.

On Sept. 30 the Gladstone local turned down the "order," for "order" it was. It could not be regarded as a "proposition," though the press so termed it. It will be noted that the company was ordered to work single shift, whereas the mine workers were not even requested to work. The law does not rest with even-handed strength on all parties in the Crow's Nest district. The mine workers are in an unreasonable mood. They demanded in June not only this single shift, but a 6-hour day. Moreover, they would not consent to three men working in a room, a plan which the company asserted would mean the gaining of 80 per cent. of their demands.

On Oct. 7, however, the Gladstone and Michel mine workers voted in favor of a return to work on the following day, thus ending this long-drawn-out and bitter strike.

Some people regard the bumps as not due to mining, but to natural movements of the earth's strata, the outcome of ill-balanced stresses in the structure of the earth. It is suggested that if the bumps are of that nature a warning might be obtained from a properly equipped seismographic station if installed nearby. It is said that F. Napier Denison, the official seismographer for the Dominion government, at Victoria, B. C., is about to establish such a station.

The region around Edmonton was formerly not unionized. Now that the union has been forced upon the operators the men do not know when they have asked enough. Some time ago they received word of the trouble at Fernie and were the first of all to telegraph their approval of the strike, and for a while it was thought that they meant to start the ball rolling with a strike in sympathy with the Fernie men.

Edmonton Strikes Must Be Fought Out

Though they have not come out on strike in sympathy with the Fernie men, some have been out on their own initiative. The 40 miners working at the Bell mine, Namao, Alta., of the Sturgeon Consolidated Collieries went on strike Sept. 16 asking for an increase in wages of 20c. a ton. Humberstone, Bush, Clover Bar, Twin City, McPeal and Dawson miners were already involved in strikes. The miners at the first of these mines, Humberstone, wanted an increase of 133 per cent.

Pictou County in Nova Scotia has had a bitter coal strike on hand. In case the reader may need some help in visualizing the location of this field, it may be said that this county faces on the north the eastern end of Prince Edward's Island, and the principal towns in the field are New Glasgow and Stellarton. The miners did not want a board of conciliation, and they opposed an increase based solely on the increased cost of living. They made demands and insisted that these demands be complied with.

They declared that this must be done at once. They were quite willing that provision be made that future increases be based on the increase in the cost of living, but the increase sought at this time, they said, must not be limited by any such consideration. No one seemed to have much hope that the trouble would soon be terminated.

Pictou County Mine Workers Go Back to Work

Charles A. Magrath, Canadian Fuel Controller, who, as noted in *Coal Age* on Sept. 26, page 618, has all kinds of powers granted him in Nova Scotia and New Brunswick, successfully turned the trick. He arrived on Sept. 25 and met the operators and operatives and soon offered the mine workers an increase of 20c. an hour, the same scale of wages as was accepted by the Dominion Coal Co.'s workmen in Cape Breton. The offer was retroactive from Sept. 1 and it will hold good for four months—till Jan. 1 of next year.

The miners' claim, that cost of living has been steadily mounting, was the cause of this short-time settlement. It is understood that a committee will study the cost of living and that a further increase in wage will be granted on Jan. 1 if the situation warrants it.

The balloting relative to this proposed settlement—inflicted on the operator and humbly requested of the mine worker after the manner of such settlements—approved of its terms. An overwhelming majority ratified it at Drummond, Acadia and Thorburn.

The miners of eastern British Columbia and parts of Alberta seem to have arrived at a point where nothing but resistance on the part of the operators and the federal officials will produce orderly conditions. Concessions merely provoke to further demands. In Pictou county the status is somewhat different.

Operator's Attitude to the Workingman

AS IT is usually hard to sell and easy to buy, the seller is suave and the buyer is grumpy. Meet the salesman in the evening, when he is a buyer of the board and lodging of "mine host," and he is a perfect bear. Nothing is right, and for nobody is there a good word. You could not imagine the pleasant salesman and the ill-tempered guest as the same man.

The relations between labor and capital resemble those between seller and buyer, but when labor is plentiful the capitalist is apt to greet applicants for work with a snarl, and when labor gets painfully scarce the reception it is accorded by capital is of the nature of a wheedling. Just now the operator is at the wheedling stage. It will not last long, in all probability, but perhaps it will last long enough for him to learn a little about the importance of the workingman as an employee and, impressed with that, he may realize the workingman's power as a voter.

As a matter of fact, to obtain the right attitude of labor to capital should be a matter of continued endeavor. The salesman always keeps the attitude of the client in mind. He knows that the reputation of his house must be above question, not only for fair dealing, but for courteous and even generous conduct. He realizes that the surest way of doing this is by personal acquaintance under especially favorable conditions. How industriously he stages such conditions and carefully watches his opportunity. The operator should try to get a similar standing with labor and should watch in like manner his opportunity for creating the right impression.

It certainly pays. A dozen corporations with a bad reputation for unfairness to labor could be mentioned. They have changed the personnel of their officials, but still the past remains to plague them. The better men have left and the less desirable men have remained, and the longer they stayed the more sour they became. The corporations in question have reformed, but they cannot get workmen from outside to see it; and they have to get along with what men they have.

If they do, by chance, bring in fresh men, it is like putting fresh milk into a bottle of soured cream. They sour also. A bad reputation is extremely hard to live down. It is far harder to bring a reputation up than to ruin a good reputation once formed. A company that has sold its men the bad goods of comfortless working conditions, poor ventilation, slow car service, high store prices, poor homes and unsympathetic management is already out of business. It has lost its trade and it can sell no longer.

By dealing solely with the flotsam and jetsam of society it may go on doing a little business, but it cannot deal with such people in the same manner as it would with the better class of men. It is trading with subnormal men, with the outcasts of other mining camps. A strong arm is necessary, and no one desires to come where such discipline is enforced. A convict camp is undesirable quarters because the rules have to be arbitrary and because the social surroundings are not pleasing. A village where a company has been unkindly has all the character of a convict camp, and continues to have it long after the management has changed for the better. The memories, the harsh judgments, the traditions of the old and evil times still hang around the very hills that hedge the plant.

Let us gather hints from the salesman and plan for good will and mutual understanding. The man who has a hard-luck story to relate about his men is like the man who regales you on the hotel porch with a story that the town you live in has the worst merchants and poorest stores in the state. It is a reflection of his own lack of success or of the poor line of his goods. He should keep his story to himself or leave town. So, likewise, with the operator who is always abusing his men. There is something wrong, of course; there is surely something wrong—with himself or his predecessors. It would be the better part of wisdom for him to say nothing.

Filling the Liberty Loan Quota

IN MINING and agricultural districts it is not difficult to fill the Liberty Loan quota. That is well shown by the fact that Iowa was the first to subscribe the required amount in the Fourth Liberty Loan drive and, in fact, managed to exceed it. Evidently the quota selected is not based on population, but on financial resources. New York City's five boroughs, for instance, are asked for $1,334,082,400. Assuming a population of 5,737,492 persons, which is the 1918 estimate of the Board of Vital Statistics of the Municipal Department of Health, this would mean a rating of $232.52 per person, earner and nonearner alike.

The rest of the United States would have to raise $4,665,917,600. The population of the United States outside of New York City may be put roughly at 100,000,000. Thus in the country outside New York City the per capita asked is $46.66. So the New York City per capita is about five times that of the rest of the country. If the village allotment were separated from the urban allotment, and the per capita of the former calculated, it would be found extremely low. What wonder then that it is easily raised!

If, however, there were no unequal Federal taxes it might, nevertheless, be easy for New York City and other urban centers to take the hurdle gracefully and near the head of the procession, for the urban sections are extremely enthusiastic in the winning of the war, having read extensively about it since the war began and at a time when the village dailies and weeklies treated the local news as more important than the news from the front.

But the cities have not only the larger quotas in the Liberty Loan, but the larger amount of taxation. If New York City is taxed only in like measure as it is asked to lend, it will have to supply $310.03 per capita this year for Federal taxes, whereas the rest of the country will supply only $62.21. Probably the difference is far greater.

No one is complaining, of course, but if the quota is hard to raise in New York City let not the rest of the country raise a clamor and talk confiscation of wealth; and if a village exceeds its quota let it not boast unless every earner in the village has bought a bond and unless the bonds that are bought are as large as each man or woman can hope to pay for in the next few months.

Elaborate charts have been prepared showing what each of us should subscribe if we do our part; but no one can really size up the duty of others without knowing their circumstances. The amount due from each of us is not a dollar less than the utmost we can spare by saving and scrimping day by day. If looking over our expenditures we cannot find a single thing that we have sacrificed, we cannot feel that we have done all that could have been done. If we have not worked at higher pressure since the war began, we have not done our part toward the greater production that the war demands.

Quotas are deceitful things. Every soldier does his utmost, bags as many Germans as he can, and, if he brings home a bigger bag than his file mate, he is back for more the next day nevertheless. The quota of each of us is the utmost that each of us can do. To all of us comes the counsel of this hour of trial: "Be an 'utmost' man."

Character of South Wales Coals

A QUESTION frequently asked by would-be coal exporters is, What is the analysis of the celebrated South Wales coal? People who hesitate to ask for the composite analysis of Illinois coal or the coal from Indiana, despite the relative similarity of the fuels in each of these states, regard it as quite easy to formulate an analysis that will represent closely the coal of South Wales. As a matter of fact, while the coals of the two states mentioned have quite a uniformity of fuel ratio, the coals of South Wales vary immensely.

Perhaps the range in Illinois coal is adequately represented by taking the analyses contained in Bulletins 22 and 85 of the United States Bureau of Mines. The extreme low value for fuel ratio to be obtained from these figures is that of the Shiloh (St. Clair County) coal, No. 8 Mine, No. 6 bed. The ratio is 0.8768. The extreme value is for a Carterville (Williamson County) coal, and is 2.0294. The range in Indiana may similarly be taken from the records to which reference has been made. The Rosedale coal in Parke County has a fuel ratio of 0.9964, whereas a sample of Dugger coal in Sullivan County has a fuel ratio of 1.4875.

Probably few realize that there is this amount of variation within the limit of these states, where uniformity of fuel ratio is the general rule. The higher ratio in Illinois is 2.31 times the lower ratio, while the relation between ratios in Indiana is 1.49. The coal in Indiana is more uniform in ratio than the coal in Illinois, though the variation in physical appearance is far greater, part of the coal in the former state being known as "block" coal and the other, strange to say, being called specifically "bituminous," though surely the block coal is every bit as bitiminous as the other.

It is common to regard the South Wales field as including all the coal area in South Wales and in Monmouthshire, though the latter county is in England. Monmouthshire is, however, populated mostly by Welshmen, and even the English people look upon the shire as a part and parcel of Wales. The report of the Royal Commission on Coal Supplies groups, under the South Wales field, the Forest of Dean and the Bristol and Somerset fields, as well as the South Wales and Monmouthshire field—but that is a purely geological assemblement and in what follows only South Wales and Monmouthshire are considered as forming South Wales, because this particular grouping accords best with popular practice. The coal progresses rapidly in its degree of carbonization as the western end of the field is approached, just as the carbonization of the Appalachian field increases as we approach its eastern edge.

But the Appalachian field is broken by an upheaval and erosion, whereas the Welsh field is almost continuous, the only break being one of about 15 miles between Carmarthenshire and Pembrokeshire. For this reason carbonization in South Wales is even more regularly progressive than in the United States, and fuel ratios of all kinds between the limits may be found. Perhaps these limits may be set between 2.246, the ratio of the Yankee seam, to 24.136, the ratio of the Cwmnant Graigola seam. This is a progression in which the highest term is 10.74 times the lowest. It will be seen that the variation in the degree of carbonization is far higher than in Illinois or Indiana. It will be readily understood, therefore, that if we would talk of South Wales coals in relation, at least, to fuel ratio and heating quality, we must specify with exactitude the location from which the coal comes; and even then we are not quite safe, so variant in fuel ratio is the South Wales coal.

So much for fuel ratio. As for sulphur, the percentage is always low. Figures to hand show that it varies between 0.05 and 2.41 per cent., though the latter figure is not representative as the sulphur percentage somewhat generally is below one, and averages 0.90 per cent. The ash percentage lies betwen 0.99 and 7.75 per cent. This last is an exceptionally high figure for South Wales coal, the average of forty records of samples in the article of F. R. Wadleigh, appearing in *Coal Age*, Feb. 8, 1913, being 2.74 per cent. In every case by ash is meant not ash plus sulphur, but ash alone.

Some of Mr. Wadleigh's authorities have added the ash and sulphur together and then quoted the sulphur separately. A correction has been made wherever the totals indicated the necessity for such revision. It must be remembered that the figures for South Wales are those given by operating concerns and may rather show the quality of the coal they are selling than the quality of the coal in the bed. The sampling is probably not as severe as that done by the United States Government. Nevertheless, if the figures given are really representative of South Wales coal as it arrives at the market, one is not surprised that it has such an excellent status wherever used.

DISCUSSION BY READERS

Wage Adjustment

Letter No. 1—In discussing, editorially, a definite and systematic way to adjust wages and other labor disputes, under the title "After-the-War Arrangements," *Coal Age* assumes a commendable attitude.

The subject of wage adjustment is not new; various schemes have been proposed, but no satisfactory solution has been reached. However, there exists today a better knowledge of the problem and progress has been made, so that we have good reason to believe that the solution is not remote and that a plan will soon be devised that will admit of no reasonable dispute.

Evidences of Remarkable Progress Made in Dealing With Labor Problems

No problem is of greater importance to the world's industries than the relation of employer to employee. In a paper read recently before the American Society of Mechanical Engineers, L. K. Comstock declares that the problem transcends in importance those of the war. In a most convincing fashion he asserts that, while little effort has been expended by either employer or employee to reach a solution for scientifically adjusting labor difficulties, there is evidence that gratifying progress has been made.

Whether belonging to the ranks of employer or employee, one should be able to approach the issue without prejudice or rancor. In the past distrust and vindictiveness have prevailed to an extent that strikes and lockouts have followed with disastrous results to both sides. Some years ago, I recall that a coal operator, replying to a request for a truce, said "I will fight until my toe nails drop off." A decade has now passed, and that man's representatives now sit in peaceful council with the representatives of the same employees, which is certainly evidence of definite progress.

The Passing of the Walking Delegate

Another evidence of progress is the growing scarcity of the walking delegate, who is invariably under the influence of the "long green." Instead, now, right and reason are being more generally recognized as the determining factors when disputes arise that threaten to destroy business or social affairs. Only recently, there appeared in Washington the officials of the United Mine Workers of America, who came to ask Fuel Administrator Garfield for the right to demand an increase in wages. Though the request was denied at the time, later Doctor Garfield took up the matter, in the interests of the hard-coal workers, and started an inquiry to establish the merits of their claim.

While some may regard this as a novel procedure, they will not deny that it is in direct line with the spirit of democracy, and is an endorsement of the sentiment pronounced by Viscount Bryce, in discussing war and progress. Mr. Bryce emphasized the power of development of reason as the guide of life and the chief source of human progress. He contrasted this with the less refined power of selfishness and of passion, which he stated were also elements of human action when social order and right is to be secured only by force.

Equilibrating Wages and Prices of Living Necessities

Referring to the statement in the editorial previously mentioned, that "wages under normal conditions determine prices," it is worthy of note that for years the Department of Labor, at Washington, has maintained an index system, to establish the rise and fall of commodity prices and wages and their relation to the price of gold. Similar indexes have been maintained for many years by the London Economist, London Statist, Bradstreets, Dun, Gibson, and others.

No argument is required to prove the truth that *wages must advance with the cost of living*, so that, as the editorial writer puts it, the "margin between price of product and cost of production will be unchanged by a change in wages." The index numbers arranged to govern the rise and fall of prices and wages and kept by different organizations prove the accuracy of the system, which fact should appeal to the employer and employee with equal force and lead them to adopt some similar method in settlement of their disputes.

The following is quoted from the Bulletin of the Bureau of Labor Statistics, No. 173, referring to the usefulness of index numbers in working out the solution to an intricate problem, such as the one under discussion, the bulletin of the Bureau of Labor Statistics No. 173 says:

> The first step in framing a clear idea of the ultimate use of the results of index numbers is most important since it affords the clue to guide the compilers through the labyrinth of subsequent choices. It is, however, the most frequently omitted. When the end in view is specific and capable of precise statement, the problem of choosing methods is comparatively simple. Straight-forward logic then determines what commodities should be included, what sources of quotations should be drawn from, and how the original data should be worked up to give the most significant results.

Urged by President Wilson as Imperative

The remarks of President Wilson, in addressing the American Federation of Labor, at Buffalo, go to show that in his opinion such a course or method is imperative. The following is quoted from his address:

> Now to stand together means that nobody must interrupt the process of our energy, if the interruption can possibly be avoided without the absolute invasion of freedom. To put it concretely that means this: Nobody has the right to stay the processer of labor until all the methods of conciliation and settlement have been exhausted, and I might as well say that I am not talking to you alone. You sometimes stop the courses of labor but there are others who do the same.

The conclusion is thus forced upon us that a formula for adjusting disturbing differences between employer and employed is being gradually but certainly reached,

and it is to be hoped that this will eliminate acrimonious discussions, which will be replaced by reason and science.

The difficulty of stabilizing wages appears to have been overcome by the United States Bureau of Labor by taking a period such as that from 1900 to 1909, inclusive. Commodity prices are averaged for the ten years of that period; referred to a base of 100. If the average of commodity prices in 3 per cent. higher for 1913, the index number will be plus 3 for that year or 103. A base or rate of wages is similarly established from the prevailing wages for that period.

Statement of Louis K. Comstock Before the American Society of Mechanical Engineers

Quoting Mr. Comstock, further, on this theory, we have the following:

> This plan has the merit of immediate practicability. The means are at hand and the machinery already is in motion for giving it a trial; whereas the alternatives, which have at various times been suggested for regulation of prices by government for preventing commodity price increases by reason of the compensated dollar having a multiple standard of value, are not easy to try because they require legislative action following a vast amount of national education.

It is recognized, of course, that a method or system such as this, to be practical and effective, can only be developed after repeated efforts. There are elements entering the problem that are yet to be considered, such, for example, are the relation of different industries to the life of operatives, and the relation of that industry to the national development.

Other features will develop that can, no doubt, be taken care of as they arise. The application of the principles, in a practical way, however, is of primary importance, and it can be confidently expected that, not only will there be more satisfactory relations of employers to their employees, but the solution of problems relating to the speeding of industry, which is most pressing at the present time, will be greatly facilitated.

Sandy Run, Penn. W. E. Joyce.

Blackdamp on Pitches

Letter No. 1—I have read carefully the inquiry of "Miner", *Coal Age*, Sept. 19, p. 568, and the answer given to his question, of whether it is possible for blackdamp to hang at the face of a chute place pitching 35 degrees.

Having had a similar experience with this so-called "blackdamp" hanging at the face of some chambers that were driven to the rise, like our friend, I too have been puzzled for a while, but came to the same conclusion as explained by the editor, who states that, owing to the mixture having a higher temperature than that of the air on the gangway, it hangs to the face of the pitch.

Applying the Temperature Test

In order, however, to satisfy myself that this was the reason and that the mixture, which would extinguish a light but showed no tendency to gravitate, was of a higher temperature, I took a thermometer into the mine and made a few tests. I found the temperature of the air on the gangway was 34 deg. F., while that of the mixture at the face of the pitch was 55 deg. F. Then I was satisfied that that was the reason it did not gravitate to the level of the road.

Allow me to add that I made a test of the effect of this mixture on the life of a tame canary and found, after exposing the bird to the mixture for three minutes, that it was none the worse for its experience. A short time after I repeated the test with the same bird, this time exposing it for ten minutes, and found that the bird then acted very weak and tired. While the mixture did not seem to bother the men who worked around it and in it all day, they were obliged, however, to use carbide lamps, in order to keep a light.

Later, an incident occurred that proved, beyond any doubt, that if the mixture had the same temperature as the air on the gangway it would fall to the bottom of the chute. Up to this time the district was ventilated by one of the first splits off the main intake and the air was quite cool. To improve the general circulation in the mine, the foreman now ordered the current reversed, which caused this district to be ventilated by the return of two gangways below. The result was that the air passing on the gangway had a much higher temperature than before the change was made. The mixture that previously hung at the face was now found on the floor, while a fresh current of air swept the face. Whether this blackdamp was being generated from the coal or where I do not know, but there was always more or less of it present in this district of the mine.

Plymouth, Penn. Joseph R. Thomas.

Justice to the Miner

Letter No. 4—Kindly afford me space in the columns of *Coal Age* to reply to the query "What Is the Matter With the Miner?" which is the title of an article by A. H. Stow, Pocahontas, W. Va., appearing in the issue of Sept. 19, p. 539.

Mr. Stowe deplores the fact that the miner is neither taking advantage of the present situation to earn the wages that he might, nor doing his full part in increasing the production of coal to meet the present demand. These may be facts so far as the miner of Pocahontas is concerned but they do not obtain in Colorado, at least at any of the mines of The Colorado Fuel & Iron Co.

Conditions in Colorado Same as in West Virginia

The same conditions exist here in respect to the location of mining camps in districts remote from the larger cities and, as stated by Mr. Stow, it is true that the miner does not have the same opportunity for amusement as the larger cities afford. He does, however, in most of the camps operated by this company, have an opportunity to spend his spare moments in profitable reading, or bowling, or playing pool and billiards in the Miners' Club House, operated by the Y. M. C. A.

Whether the living conditions and opportunities for recreation are better in Colorado than in West Virginia, I am unable to say. I do know, however, that our miners have responded nobly to the demands of the war, by working more diligently and producing a larger average daily tonnage than they did prior to the war, or prior to the present high scale of wages.

Let me say that I am inclined to the opinion that, in localities where this is not the case, the miner may not have been properly informed or appealed to by his company. The Colorado Fuel & Iron Co. took steps, early in the war, to keep their employees informed through reading matter given them and mass meetings held. The result is that we have been much gratified at the response our miners have made by working more steadily and producing larger tonnages. There has been no occasion when they have not responded after the situation has been made clear to them.

The company has also kept a record of the percentage of possible shifts worked, and have posted, at each mine, the figures showing the employees what their own record was for the preceding month, as well as the record of every other mine operated by the company. We believe that this plan has created some rivalry and stimulated production. The records for June, 1918, showed that 90.03 per cent. of the possible shifts were worked; for July, 92.71 per cent.; August, 92,78 per cent.; September, 95.46 per cent.

The Colorado Fuel & Iron Company's miners have also responded liberally to all war funds and bond issues.

In my opinion, coal miners are just as patriotic as any class of workmen in the country, and are just as anxious to do their part. However, they must depend to some extent on their employer to keep them informed as to what their duties really are and what is expected of them.

E. H. WEITZEL,
Pueblo, Colo. Manager Colorado Fuel & Iron Co.

Accounting of Materials

Letter No. 1—Observing the request of "Office Manager," *Coal Age*, Aug. 29, p. 417, for suggestions regarding the best methods to be employed in the accounting of mine supplies and materials, I beg to submit a few remarks based on my own experience in the handling of supplies at mines during the past fifteen years.

Now, more than ever before, when the prices of both labor and material are soaring, it is of the utmost importance that the company or owner should know where and for what purposes the money is expended. Labor and material are the chief factors in the operation of mines and as such require the strictest regulation.

First, then, it is necessary to have a good storehouse where all needed supplies and material can be kept on hand ready for immediate use when occasion requires, and where perishable goods and valuable material will be protected from the weather and from theft.

The storehouse and its entire contents should be in charge of a reliable and competent clerk or storekeeper, who must be held responsible for all material received and given out. To enable him to do this properly a stockbook must be provided. I am permitted to offer below a sample page form of stockbook used at our collieries. The form shown here is one of the pages designed for entering material ordered each month, such as track material, piping, shafting, etc. There are other pages similarly ruled, but designed for daily consumption of the numerous smaller items that are constantly being required. These include such articles as nails, bolts, oil, powder, tools, etc.

The daily posting of supplies given out is absolutely essential to the right conduct of a storehouse. The work of caring for and accounting of these various supplies requires a good clerk. Experience shows that when either an inside or outside foreman is charged with this duty, the results are unsatisfactory and the company suffers a loss. A foreman who is pressed with too much clerical work ceases to be a competent foreman and, in many instances, makes a poor clerk besides.

THE "FOLLOW-UP" PLAN A MOST IMPORTANT FEATURE OF ANY ACCOUNTING SYSTEM

The groundwork of any accounting and supply-distribution system is the "follow-up" plan. The person in authority must see that all material is used for the purpose and in the place for which it was ordered. This is specified on the requisition, which must be certified by the mine foreman as needed for the purpose named, and duly authorized by the superintendent or manager, before it can be honored by the storekeeper and the material delivered.

The form of such requisition, as given here, shows the monthly requirement when possible, the quantity on hand, previous orders unfilled, quantity required, kind of material, its use or purpose, approximate value and order number. The requisition bears the date when it is presented and is made out in duplicate, the original being sent to the general manager, as soon as it is filled, and filed in his office, while the copy is retained by the storekeeper, for reference. The same form of requisition is used when the material wanted is to be furnished by the purchasing agent, the office, warehouse or any of the shops or other departments of the company.

Another blank form is used by the storekeeper or other person when delivering goods or material. As

It is made out in triplicate, the storekeeper who delivers the goods to the teamster, and the party who finally receives them keeping their respective forms for reference, while the teamster, after delivery, sends his receipt to the office.

Speaking of "following up" a requisition, it is not only important to see that supplies and material furnished are actually used as intended and not appropriated or carried off by individuals, but the department filling the order should see that material having a higher

market value is not used when cheaper material will give the service required. For instance a foreman may, without thought or knowledge, specify bronze or brass when iron would answer the purpose.

The Pennsylvania Railroad employs inspectors whose business it is to check up all material stocks on hand in its offices, towers, warehouses and section houses and report monthly. While I have no desire to advocate an increase of official duties, it is my belief that the right sort of supply "follow up" will require a similar check-

ing system applied oftener than the customary yearly inventory.

In order to obtain the best results and secure the highest economy in the use of material, the storehouse and, in fact, each department of the company should be considered as a separate and independent business having its own head and organization, and selling its products to the operating department at a sufficient profit to cover its own overhead charges. On the other hand, it should receive and credit the operating department with all unused material and scrap. If supplies of any kind are sold to individuals a fair profit should be realized on such business, and a statement sent to the office, showing kind, quantity, cost and selling price of the articles sold.

While all supplies and material should be issued, as previously stated, on an authorized order or requisition, the rules should be flexible enough to allow of material being secured for any emergency, on the assurance that the order for the same will follow. This is necessary in order to avoid an expensive delay in the operation of the mine when a breakdown has occurred and repairs must be made at once.

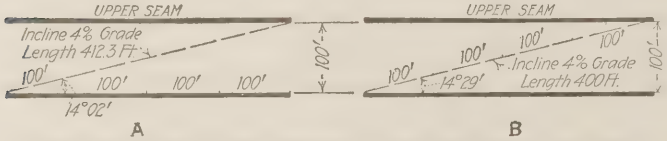
Many mine foremen are averse to writing orders for material needed in the mine, but they should be obliged to abide strictly by the rules, and a statement should be rendered each foreman, showing his material cost and credits for the month. The danger in supply accounting lies mainly in the fact that a foreman desiring to make a good showing will frequently sacrifice the upkeep of equipment in his charge.

Two instances of this came to my notice a short time ago. In the first, the attempt to cut down the operating expenses at one colliery resulted in such a sacrifice of boiler-room equipment that a chemical test of the ash dump, made a little later, showed an unwarrantable loss in the generation of power, and the needed repairs were then quickly made.

In the second case, the habit of the officials to cut requisitions led, on the death of the colliery machinist, to the discovery of a regular storehouse of brass and other supplies hidden beneath the shop floor. I cite these instances, which are not uncommon, to show the importance of pursuing a wise course in the supply of material required. There should neither be "feast" or "famine," but a workable stock sufficient for every call should be available at all times, at every mine.

——— Penn. J. KENVIN.

INQUIRIES OF GENERAL INTEREST



Estimating Percentage of Grade

Recently we have been having an animated but very friendly dispute as to the proper method of estimating the percentage of the grade of an incline. The question under discussion is, What would be the length of a plane between two level seams of coal separated by 100 ft. of rock strata? The plane is to be driven on a 25 per cent. grade.

Using the method that I have been taught to apply in such cases, I find the length of the plane, in this case, to be 412.3 ft. One of the best mine foremen in this valley, however, disputes this result, claiming that the length of the plane should be exactly 400 ft.

Comparing his method of calculation with my own, I find that the difference lies in the fact that he estimates the percentage of grade as being the rise in 100 ft. of pitch distance, while my understanding is that the percentage of grade is based on horizontal measurement. For example, in the present case, the 25 per cent. grade would represent a rise of 25 ft. in 100 ft. of horizontal distance. The question is, Which of these methods is correct?

In order to present the case clearly, I have shown in the accompanying figure my own method at *A* and

ILLUSTRATING TWO WAYS OF ESTIMATING GRADES

that of my friend at *B*. In each of these, the two seams of coal are shown as separated by 100 ft. of strata, and the incline, in each, is indicated by the dotted line. The sketch *A* shows the measurements to be taken in 100-ft. lengths on the horizontal line, while in *B* they are shown as taken on the incline.

In order to find the length of the incline, in the first instance (*A*), it is necessary to find the pitch angle or the angle between the incline and the horizontal. The tangent of this angle is equal to 25 ÷ 100 = 0.25 and the corresponding angle is 14° 02′. The length of the incline is then found by dividing the distance between the two seams (100 ft.) by the sine of this angle; thus, 100 ÷ 0.24249 = 412.3 ft.

Referring now to the second method, shown at *B*, it is clear that if the incline rises 25 ft. in each 100 ft. of pitch distance, there will be as many hundred-foot measurements as the rise per hundred feet is contained in the distance between the seams, or 100 ÷ 25 equals four 100-ft. measurements. The length of the incline, in that case, would be 400 ft. Kindly say which of these two methods should be used. MINING ENGINEER.

Scranton, Penn.

Replying to this correspondent, it can be stated that both of these methods are equally correct and both are in use. The usual practice in slightly pitching seams, however, is to estimate the percentage of grade as the *rise per hundred feet of horizontal distance*. Many engineers, also, prefer to use this method in fairly steep seams, the advantage being that the measurements are all taken in the horizontal plane and can be platted on the map without change.

On the other hand, a very common practice in steeply pitching seams is to make all measurements on the pitch, and in such cases many engineers prefer to estimate percentage of grade as the *rise per hundred feet of pitch distance*.

Of course, it is always necessary, in stating the percentage of grade, to understand clearly whether such percentage is based on horizontal or on pitch distance, since the results obtained are different in each case. That is to say, a 25 per cent. grade, based on horizontal measurement, does not represent the same incline as a 25 per cent. grade based on pitch measurement.

As previously stated, some engineers would prefer one method and others another, both being equally correct. Many misunderstandings and disputes have arisen similar to this one, because the parties do not recognize that the percentage of grade given may have been computed on the horizontal or plat measurement, which we believe the more common practice in coal mining, except where the seam has a high pitch.

We shall be very glad to have engineers and mine surveyors give their own preferences. The discussion will no doubt show the importance of understanding whether a given grade is based on horizontal or on pitch measurement, as otherwise grave errors will frequently result in the interpretation or reading of mine maps. The discussion should show the relative advantages of the two methods.

Calculating a Room Switch

We are opening a new mine and have decided to adopt a track gage of 42 in. The roof and floor conditions are such as not to permit driving entries or turning rooms a greater width than 12 ft. We shall use a car having a length over all of 8 ft. 9 in.

Kindly permit me to ask some of the practical readers of *Coal Age* to inform me what should be the dimensions of a room switch that will give the most satisfaction, under the conditions I have mentioned, and what frog number would give the best results.

————, Tenn. MINE FOREMAN.

This is a good practical question on the solution of which very much of the successful operation of a mine will depend. The theory of calculating the correct dimensions of mine switches has been explained so often in *Coal Age* that we are glad to submit this inquiry to our practical readers for their solution, which we hope to receive,

EXAMINATION QUESTIONS

West Virginia Examination (1918) Mine Foreman and Firebosses

(Selected Questions)

Ques.—How would you determine the quantity of air passing, where the section of the airway is 9 ft. 6 in. wide and 5 ft. 3 in. high?

Ans.—Measure the velocity of the air at that point of the airway, being careful to obtain a fairly approximate average reading for the entire section. Then calculate the sectional area of the airway, thus: 9.5 × 5.25 = 49.875, say 50 sq.ft. Assuming an average velocity, at this point, of say 600 ft. per min., the quantity of air passing is 600 × 50 = 30,000 cu.ft. per minute.

Ques.—In a gaseous mine where 175 persons are employed, would you consider the ventilation sufficient, providing the quantity of air in circulation is equal to 150 cu.ft. per min., per man?

Ans.—The West Virginia mining law (Sec. 26) requires the circulation of 150 cu.ft. of air per min., per man, in mines where there is danger from gas being liberated, and as much more as the district mine inspectors may deem necessary. The circulation must, therefore, conform to these requirements of the law. Conditions may arise, however, between the visits of the district inspector, that would call for the judgment of the mine foreman in regard to the sufficiency of the air in circulation. The foreman must decide these conditions according to his best judgment and experience, basing his decision on the percentage of gas in the air and the quantity of dust carried in suspension in the current, having due regard to the inflammability of the coal and the fineness of the dust.

Ques.—Under what circumstances may a body or an accumulation of gas fail to be removed after the ventilation has been restored?

Ans.—The circulation of air may not reach the body of gas accumulated at the face or in cavities of the roof, and it will then be necessary to erect brattices to cause the air to sweep those places. Again, the velocity of the air may be insufficient to remove the gas, which is frequently the case when methane or marsh gas has accumulated at the face of a pitch or blackdamp at the face of dip workings. In either case, a strong current of air is required to drive out the gas or force it from its lodging place.

Ques.—(a) Would you consider it safe to work with open lights in any portion of a mine liberating explosive gas? (b) What precautions would you take to insure the safety of the workmen? (c) What material should be kept on hand at mines liberating explosive gas? Answer fully.

Ans.—(a) Assuming the conditions in the mine are such as to require the use of safety lamps in one or more sections of the workings, it would not be safe to use open lights in any portion of the mine whatever. In other words, mixed lights should never be used in a mine.

(b) In a mine generating gas in dangerous quantities, safety lamps of an approved type should be used exclusively. These lamps should be the property of the company and inspected, cleaned and filled by competent lamp men, after each shift. All lamps should be numbered to correspond to the check numbers of the men and should be delivered to them in return for their checks, as they enter the mine. No man should be permitted to use or handle a safety lamp in the mine, until he has given evidence that he understands the principle of the safety lamp and its proper use. The fireboss should observe closely the lamps of the men when making his daily rounds, and give them any needed instructions in regard to their proper use.

(c) At all mines liberating explosive gas, first-aid outfits should be kept at convenient points in the mine and on the surface. The outfits should include pulmotors, oxygen tanks and breathing apparatus of approved type. There should also be provided stretchers, blankets and waterproof coverings ready for immediate use.

Ques.—Under what conditions would you recommend and use mixed lights in a mine?

Ans.—Under no conditions should mixed lights be used in any mine.

Ques.—State in detail your opinion of the causes of the explosions that have occurred in this and other states and state what, in your opinion, can be done to prevent these disasters?

Ans.—The chief causes of mine explosions are the following: Reckless use of powder and other bad practices in blasting; disobedience of mine workers to the instructions given them and to the rules and regulations of the mine; lack of supervision on the part of mine officials; disregard of the provisions of the state mining law; the improper handling of or meddling with safety lamps.

To prevent these occurrences, a closer supervision of the mine is required and a strict compliance with the mining laws, together with greater mine discipline and a higher regard for safety on the part of mine officials.

Ques.—When does a fireboss' duty in the mine cease and what are the duties of each miner upon entering his working place?

Ans.—The duties of a fireboss in the employ of a coal company do not cease, as long as he is within reach or call. Should any condition develop requiring his presence, it is the duty of a fireboss to respond promptly to a call for assistance. A miner's first duty on entering his place after absence is to observe its condition, examine the roof and reset any timbers that he finds have been displaced.

COAL AND COKE NEWS

What Happened in September

[The bracketed figures in the text refer to pages in the present volume and should the reader desire further information he can obtain it by reference to the pages indicated.]

Sept. 2—Flood invades Mary Lee mine of Alabama Co. at Lewisburg, Ala., and drowns two men [525].

Sept. 3—William G. McAdoo makes report to President saying, "It is probable that adequate transportation for the fuel requirements of the Nation will be available provided the coal production during the warm weather can be maintained at a point that will fully employ the cars requisitioned. (This report was held for some time before publication.)—Preference list No. 2 of the Priorities Division of the War Industries Board is issued, but is not made public till Sept. 8 [514]—United States Fuel Administration revises prices of coal at mines in Wise County, Texas, and provides for summer reductions from these standard prices—Rocky Mountain Mining Institute holds annual meeting in conjunction with American Institute of Mining Engineers; to last till Sept. 6 [633-641].—United States Fuel Administration reduces price of byproduct coke 30c. a ton throughout the United States except in the states of Alabama and Washington [513].

Sept. 4—United States Fuel Administration grants companies the right to charge reasonable switching charges where these have been paid to the shipping railroad for the diversion of coal wherever such diversion has been ordered by the Fuel Administration to relieve a shortage of fuel—Believing that the labor employed in the reclaiming of the good material in breeze dumps at beehive coke plants could be better employed in the work of manufacturing coke, such reclamation of breeze is prohibited by the United States Fuel Administration—United States Fuel Administration forbids any producer in the high-volatile coal-producing districts of the Thacker and Kenova regions of West Virginia and Kentucky and along the Kanawha & Michigan, the Kanawha & West Virginia and the Coal & Coke (West of Dundon) railways and their short-line connections; also in the eastern Kentucky fields along the Chesapeake & Ohio and Sandy Valley and Elkhorn railroads and their short-line connections; also in the Logan and Kanawha districts west of St. Albans, W. Va., along the Chesapeake & Ohio Ry. and short-line connections; also in Virginia along the Louisville & Nashville R.R. in Kentucky along the same road and the Cincinnati, New Orleans & Pacific Ry. and their short-line connections; in Tennessee along the line of the Cumberland Valley Division of the Louisville & Nashville R.R. and along the Middlesborough R.R. to sell, ship or distribute their coal to dealers and consumers for use or consumption in the lower peninsula of Michigan except after a permit has been given [513, 648]—United States Fuel Administration forbids any producer in the coal-producing districts of Ohio and in the coal-producing districts located on the Ohio River division of the Baltimore & Ohio R.R. in Mason County, West Virginia, to sell, ship or distribute coal to points in the lower peninsular of Michigan located on or east of the line of the Grand Rapids & Indiana R.R. and its branches except when granted a permit [513, 648]—United States Fuel Administration grants permission to any Illinois producer to ship to that portion of the State of Wisconsin on and north of a line coincident with the Green Bay & Western R.R. from Kewaunee, Wis., to Amherst Junction and thence coincident with the Minneapolis, St. Paul & Sault Ste Marie R.R. through Abbotsford and Chippewa Falls to Minneapolis, Minn. [513, 648].

Sept. 5—Annual meeting of New York State Retail Coal Dealer's Association.

Sept. 6—Conferring with his railroad chiefs of the Eastern region, William G. McAdoo declared: "There is no chance of another great railroad tie-up such as was experienced last winter, and there is no danger of a fuel débâcle so far as the railroads' part in preventing one is concerned. The roads will be able to handle all the coal that the miners can extract [556]—Judge Edwin B. Parker, the priorities commissioner of the War Industries Board, formulates lists of the priority of works needing new permits or licenses [514].

Sept. 7—Arrangement made by United States Fuel Administration by which the Consolidated Coke Co. of Pittsburgh pays $80,000 to the Steel Company of Canada, of Hamilton, Ont., and to the Thomas Iron Co., of Hokendauqua, Penn., for poor coke delivered to them [557].

Sept. 8—Bernard M. Baruch, chairman of the War Industries Board, lists in Class I for preferential treatment under the new selective-service legislation, plants producing coal, those engaged principally in manufacturing mining tools or equipment, those engaged principally in producing metallurgic coke and byproducts including toluol—Motor runners in four mines of the Delaware & Hudson Co. go on strike [558].

Sept. 9—National Coal Association points out the falsity of William G. McAdoo's statements relative to the ability of the railroads to handle all the coal offered to them [556]—The West Virginia and Kentucky Coal Co., on Smoot Creek, Letcher County, Kentucky, ships its first consignment of coal [714].

Sept. 10—By the fall of a cage in the Protection Island shaft at Nanaimo, B. C., 16 miners lost their lives [617].

Sept. 11—W. J. Murray, chairman of the executive committee of the Victor-American Fuel Co. and a well-known coal expert, dies at La Jolla, Cal. [643].

Sept. 12—Tipple of the Ella Mine of the United Coal Corporation falls on tracks of the Pittsburgh & Lake Erie R.R., carrying down three men who, nevertheless, escape uninjured [618]—Logan Coal Co., of Philadelphia, Penn., is fined $25,000 and money is given to Pennsylvania chapter of the American Red Cross. It is charged with selling coal as smithing coal that was to be used for other purposes, so as to get the higher price. It is required to make equitable return of money to all parties that had been overcharged.

Sept. 14—The United States Fuel Administration announces a revision of the regulations governing the storage of coal by consumers of different classes [602].

Sept. 15—Big production meeting of West Virginia operators held at White Sulphur Springs, W. Va. [605].

Sept. 16—Big strike occurs in the southern anthracite field, the miners demanding the United States Fuel Administration to decide, at once, on the increase of wages to be provided [607]—Annual congress of National Safety Council at St. Louis meets; to last till Sept. 20 [502-503].

Sept. 17—Four collieries of the Delaware & Hudson Co., Grassy Island shaft, Grassy Island slope, the Olyphant and Eddy Creek collieries, return to work [650].

Sept. 18—Senator Myers, of Montana, introduces a bill prohibiting the sale of intoxicating liquor within 5 miles of coal mines for 60 days after Oct. 1.

Sept. 19—Southern anthracite strike practically comes an an end [607]—Meeting of operators, officials of insurance companies, mine inspectors and officials of the Harrisburg headquarters of the Department of Mines convenes in Harrisburg for readjustment of insurance rates particularly for anthracite mines [662].

Sept. 21—The mine workers of District No. 1 of the anthracite region, representing 70 local unions, protest against the declaration that they are not patriotic and promise to coöperate with United States Fuel Administration [650]—Plant of Hazard Coal Co., Hazard, Ky., is destroyed by fire [663]—Gladstone and Michel locals vote not to return to work till single shift is reëstablished—Union leaders in District 18 suggest that an arrangement be made establishing the single shift for 30 days during which time the single shift might be discussed.

Sept. 23—Explosion at the mine of the Franklin Coal and Coke Co., Royalton, Ill., kills 23 men [714].

Sept. 24—Elbert H. Gary, chairman of the board of directors of the United States Steel Corporation, declares in favor of the 8-hour day [650].

Sept. 25—Mine workers at Fernie declare that they will call out firemen, pumpmen and fanmen if their demand for a single shift is not conceded without reservation and a promise made to give all men work within 30 days—C. A. Magrath, fuel controller of Canada, met Pictou County, Nova Scotia, mine workers and operators and suggested a 20c. per hour increase in wage to the former, retroactive and good till Jan. 1.

Sept. 27—Dr. H. A. Garfield denies that he or the Federal Fuel Administrator for New York has issued an order that coal be not used for heating before Nov. 1—Committee on mechanical labor-saving devices in mining appointed — Pictou County, Nova Scotia, strike comes to an end—W. H. Armstrong orders that the Crow's Nest Pass Coal Co. work single shift and proposes that a Royal Commission review the dangers in the mines of the company and report with recommendations.

Sept. 28—The Fourth Liberty Loan campaign for $6,000,000,000 starts.

Sept. 30—Gladstone local in Fernie, B. C., turns down proposition conceding the single shift but providing for the appointment of Royal Commission to ascertain just what attitude should be taken toward the practice of running a mine more than one shift in 24 hours.

Harrisburg, Penn.

Officials of the State Department of Mines are making an effort to learn the number of abandoned mines or workings in both the anthracite and bituminous fields which have been reopened or which it is planned to put back into operation this winter. The number is believed to be greatest in the soft coal field, and there have been reports received here of mines which have been idle for so long a time that weeds and brush grown up about the openings have to be cut away to enable examinations to be made. Some of these are to be started again. In the anthracite field there have been some surveys made to determine how soon certain veins can be reached. If all the plans that have been heard at the Capitol materialize, there will be a large increase in the production of coal next year.

The rapid progress of the Spanish influenza epidemic in the coal regions has had a noticeable effect on coal output, and it is feared that unless the epidemic is checked shortly the output for October will be cut to a greater extent than realized. The military authorities of the State are coöperating with the State Health Department to prevent a further spread of the disease and to more adequately handle the cases now reported.

Fifty-eight deaths in one day was the record for the little mining town of Minersville, in the Schuylkill region, and other mining towns are reporting many deaths. The epidemic has caused a number of collieries to close down entirely. The State Department of Health has ordered all saloons, moving picture houses, churches, etc., to close until the epidemic is over.

Uniontown, Penn.

A drop of 27,000 tons of coal over the output of the preceding record-breaking week is shown in the official fuel production figures for the week ending Oct. 5. The showing was admittedly disappointing, despite the fact that curtailment of power service hampered the output and that an alleged flourishing business in the sale of liquor through the region affected the individual efficiency of the men. The coal shipments for the week were 227,263 tons and the coke shipments 427,449 tons.

Effect of the Spanish influenza epidemic which has hit several plants in the region is causing some concern, the most serious trouble so far being reported at the Continental No. 2 plant of the Frick company,

where drastic steps quickly got the disease under control but only after quite a few cases had been reported.

Especially interesting in this connection just now will be the effect of prohibition in the coke region as a result of the order closing the saloons throughout the state to prevent the spread of the influenza epidemic. Operators and producers for months have been vigorously demanding prohibition, and the results of the closing of the saloons in the county are being followed with more than usual interest. While the sale of liquor has not been entirely eliminated in the region as a result of the order, officials feel that the saloon closing order will have a noticeable effect in the production.

Charleston, W. Va.

Power shortage, late placements and a dwindling car supply as the week progressed figured largely in limiting production in the Fairmont district last week. On the first day of the month the supply—1420 cars—was considered rather a good one. Of this number 1118 cars had been placed at 7:00 o'clock in the morning, but on the same day many mines were operated with difficulty owing to their inability to secure enough power. On the 2d the supply dwindled to 1230 cars. On the same day an order came directing all box cars on all sidings to be shipped west for the shipment of grain, the significance of the order being that it meant that team and truck loaders, for the time being at least, would be no longer supplied even with box cars for the loading of coal. It is estimated that 22 mines in the region will be affected, and that production will be curtailed to the extent of 200 cars of coal a day. Car shortage was at its worst, however, on the last day of the week, when there were but 612 cars supplied, only 387 of them being placed at the usual hour for beginning the day's work. Wrecks and the influenza were said to have upset transportation conditions on the Baltimore & Ohio R. R. Production in the Pocahontas and Tug River District is the second best since last March. Production for the week mentioned reached a total of 469,732. A special drive is being made in the Tug River and Pocahontas districts to reach 2,000,000 tons during October, and gains are being made day by day. The coal will probably be reached unless Spanish influenza affects the man power of the district.

The shipment of coal from the Guyan field is steadily on the increase, the car supply in the district having made that possible. The movement of coal to the lakes from this district will be continued throughout October. Tidewater tonnage is very heavy now and is increasing constantly.

Production in the Kanawha District is now at the rate of 40,000 tons a week more than it was at the close of August. Production during the last week of September had almost reached the high-water mark for the year, but a loss was sustained last week, the total output being only 204,438 tons as compared with 217,000 tons for the week previous, a decrease of 13,000 tons, produced in 6065 working hours. Losses from labor shortage amounted in hours to 794 and production loss from car shortage to 466. Car service for all the mines in the Kanawha region was all that could be desired, but cars were late in being placed.

Production has shown a decrease during the last week in both the New River and Winding Gulf districts, but this week there is said to have been an improvement. Operators contend there are certain neutralizing influences at work in the district. However, coal men are confident that production for October will average well above that for September.

Birmingham, Ala.

Disappointment is noted over the figures for the week ending Sept. 28, when only 383,067 tons of coal were produced in Alabama, against 383,142 tons for the week ending Sept. 21. Coal production in the state during the entire month of September amounted to only 1,544,769 tons.

Explanations continue to point to faulty railroad car service, unsteady labor and natural causes. However, coal mining in the district has been active during the last week, and the hope is again advanced that the official figures for the week ending Oct. 5 will show an increase of at least 17,500 tons over the production of the previous week. There is being made an appeal for renewed efforts on the part of all mine workers and operators to swell the coal production totals, in an effort to make up a portion of the shortage of output. A weekly production of 425,000 tons or more is the goal now being sought.

Within three months coal will be produced at the new mines of the Republic Iron and Steel Co. at Risco, in the extreme western portion of Jefferson County. A large coal washer is being installed at the mines, and the Republic company is spending $500,000 on improvements. Daily production of the new mines, when full operation is begun, is expected to total in the neighborhood of 1200 to 1500 tons.

It is also announced that by January, 1919, fuel production at the mines of the Railway Fuel Production Co. at Parrish will total over 1000 tons of coal daily. Increased production of coal at Getmore, in the lower part of Jefferson County, is also looked for in a short period of time.

Employees are being assured that they will be cared for when their names are reached in the selective service call list. The Alabama Coal Operators' Association has received information from the Production Committee of the National Fuel Administration that pick miners are regarded as being engaged in an essential industry. This information is being given wide publicity throughout the district.

After many promises of service, transportation of coal on the Warrior River will begin Nov. 1, according to a statement made in Mobile by Henry DeBardeleben, Federal Manager of Warrior River traffic. Regular barge service will be inaugurated between Mobile and New Orleans, and Mobile and Cordova, on the Warrior, on that date. Six self-propelled barges will comprise the initial fleet. Other barges will be put on after November 1, as the traffic increases.

Coke production in the Birmingham District continues to be found somewhat short, both in quantity and quality. Attention is being given this commodity, however, with hope of marked improvement by gradual degrees.

Victoria, B. C.

British Columbia's production of coal for the month of August totaled 240,055 tons, which is an increase of 13,467 over July, and the highest tonnage produced in any month so far this year. Vancouver Island takes the lead in comparison with the output of other Provincial collieries, having 145,266 tons to its credit. The Crow's Nest Pass mines are next with 78,971 tons, while the Nicola Princeton District shipped 15,818 tons.

Of the Island companies the Canadian Collieries, Ltd., have the best showing with 71,791 tons, the Canadian Western Fuel Co. following close with 61,200 tons. The balance is accounted for by the smaller collieries as follows: Pacific Coast Coal Mines, South Wellington, 6858 tons; Nanoose Collieries, 2631 tons; Granby Consolidated Mining and Smelting Co. (Cassidy's), 2383 tons; British Columbia Coal Co. (Jingle Pot), 400 tons.

In the Crow's Nest Pass District the Crow's Nest Pass Coal Co. produced 66,457 tons from the two collieries operated, as follows: Coal Creek Colliery, 44,366 tons; Michel Colliery, 22,091 tons; Corbin Coal and Coke Co., 12,514 tons.

The Middlesboro Collieries were the biggest producers in the Nicola Princeton District with a tonnage of 8529, the remainder coming from the smaller collieries.

The new mines being opened on the Island are beginning to count in the monthly production, these recently opened up at South Wellington and Cassidy's having an output of 5530 tons for the month, while it also is to be noted that the Jingle Pot, for months sealed by order of the Chief Inspector of Mines because of fire, is again on the shipping list. But the most remarkable gain is that of the Harewood mine of the Canadian Western Fuel Co., which was recently reopened and last month produced 21,695 tons.

At the other new mine, which is being opened by the Canadian Western Fuel Co. on the farm near Nanaimo, rapid advances are being made. Two shafts are being sunk to tap the Wellington Seam, and one of these struck the coal a few days ago, exposing a seam about 9 ft. in thickness. The other is expected to reach the same seam some time during the present month.

The total production of the coal mines of British Columbia so far this year is 1,822,031 tons. For the same period last year it was 1,535,998 tons. Therefore there has been a gain of 286,033 tons.

PENNSYLVANIA

Anthracite

Mahanoy Plane—The Stanton, Lawrence and Bear Ridge collieries at this place, twice abandoned as worked out, are now producing hundreds of tons of coal daily under Madeira Hill & Co.'s direction.

Mauch Chunk—Hacklebernie, the first anthracite mine in the world opened after the discovery of the hard-coal at Summit Hill in 1794, and closed years ago by the Lehigh Coal and Navigation Co., will shortly be opened by the Mount Pisgah Coal Co., of this place.

Hazleton—The Morea colliery of the New Boston Coal Co., southwest of Hazleton, has been electrified throughout and the use of steam and mules discontinued. Many thousands of dollars were spent in making the change, and no time was lost in producing coal, all the work being done Sundays and at night.

The Hollywood colliery of Pardee Brothers & Co. at Hazleton, abandoned 30 years ago, has been reopened. The operation furnishes employment to about 200 mine workers.

Wilkes-Barre—Damage in excess of $50,000 was caused in the town of Plains on Oct. 9 when a cave-in of coal veins in the Conlon mines let down the earth between a block of houses fronting on Main and Maffett Sts. One wall of the new Plains high school was shattered. Miners had been warned, and there was no loss of life.

Larksville—The Delaware & Hudson Coal Co. has taken steps to aid the men in keeping down their monthly expenses by reason of the increased carfare from Plymouth to the collieries in this district. The officials have placed a small mine locomotive with a string of cars at the disposal of the men. An effort is being made to have several passenger coaches placed.

Ashley—Scarcity of timber for use in and about the mines is giving the coal companies much concern at this time. Though the operators here have a considerable stock on hand, yet they fear they will have difficulty replenishing their stock when cold weather sets in. It is for this reason many of the collieries are buying heavily of timber and using all possible means to secure an ample supply. The Lehigh & Wilkes-Barre Coal Co. has installed a complete milling outfit and is rapidly taking all the available timber from its property, especially on the mountains in the Wilkes-Barre district.

Mahanoy City—One of the largest sales of coal lands that has occurred in the southern anthracite fields for some time was consummated by the delivery recently by the heirs of the late John Farnum to the Lehigh Coal and Navigation Co., of a deed for the Farnum interest in a tract of land long known as the Farnum and McGinnis tract containing 202 acres situate in the boroughs of Mechanicsville and Point Carbon, the townships of Norwegian and East Norwegian and the City of Pottsville and embracing much of Lawton's Hill within its lines. The tract contains rich coal deposits which will in a short time be worked by the Lehigh Coal & Navigation Co. The price paid for the land was $1200 per acre for a fee simple title. Where only the coal reserve was purchased the price was $700 per acre.

WEST VIRGINIA

Logan—The Gay Coal and Coke Co., by opening entry No. 21 to Coal Branch, will be able to give the loaders more cars. A steam locomotive has been purchased by this company in order to insure the loaders a better supply of cars.

Charleston—Having purchased nearly 2000 acres of coal land on Campbell's Creek, Kanawha County, D. Lewis, who has extensive operations in the county, will proceed in the near future to develop the tract acquired by him. It is said that Mr. Lewis paid an average price of $10 an acre for the coal property, which was acquired from Josephine D. Taylor, of New York.

Huntington—The Amherst Coal Co., operating in Logan County, has installed facilities for storing from 8000 to 10,000 tons of coal at a time when cars sufficient to load the coal are not available. The company uses a steam hoist for loading coal into the cars and the company has found it possible to load a railroad car in 22 minutes.

Fairmont—In connection with the recent organization of the Dawson-Connellsville Coal Co., it is the purpose of the new company to double the capacity of the plant acquired by the company together with a 100-acre tract of Sewickley or Mapletown coal located just below Monongah, on the east side of the West Fork River. The company acquired a mine producing 500 tons daily and proposes to increase the capacity of 1000 tons per day. The mine is a drift opening and is drained naturally.

OHIO

Piney Fork—The Piney Fork Coal Co., with headquarters in Columbus, had its gigantic steam shovel at the stripping operation near here buried by a slide, and the operation was idle for about two weeks. It will soon be in operation.

Zanesville—Six miners living near Zanesville and employed in surrounding mines have been placed under arrest by United States authorities on the charge of stirring up disaffection among the miners of that section. The arrest was made by U. S. Deputy marshals and government secret service operatives. The men will be held on the charge of sedition.

KENTUCKY

Jackson—Baker Brothers have purchased coal land on Frozen Creek and plan early developments.

Willard—The Black Raven Coal Co. will install electrical machinery, increasing daily output to 1000 tons.

Madisonville—C. B. Curtis, president of the new Curtis Coal Co., is having some trouble in getting a switch into the company's new property at Madisonville, and has taken the matter up with the officials of the Louisville & Nashville R.R. Co. in order to get action.

Hazard—The Daniel Boone Coal Co. is nearing completion of its new mining camp at Heiner, in the Hazard field, and the third mine of the group will be started about Dec. 1. The company will have a modern camp, with much better features than commonly found in the district. The operations are on a part of the Maynard Coal Co.'s interests.

INDIANA

Vincennes—The Pike Coal Co. mine, near Petersburg, Ind., was destroyed by fire, said to have been of incendiary origin, early on Oct. 7. The loss is estimated at $125,000. The mine had recently been remodeled, the tipple enlarged and the capacity increased to 3000 tons per day. Officers of the company said an effort would be made to rebuild at once.

ILLINOIS

Royalton—Mine rescue teams from Duquoin, Dewaine, Benton and Herrin recovered 14 bodies on Oct 13 from the north mine of the Franklin Coal and Coke Co. The men, with seven others whose bodies were recovered earlier, were killed by an explosion a week before. It will probably be two months before the mine can be operated again.

Danville—The Hartshorn mining interests in Danville, Ill., and Ohio districts have been sold for approximately $2,000,000, the purchasers being Chicago, New York and London capitalists, headed by George C. Moore. The properties consist of the Beech Flat Coal Co., of Ohio, and the Mission Mining Co., Two Rivers Coal Co., Carbon Hill Coal Co. and Hartshorn Coal Co., all of the Danville district. Mr. Moore is well known in Chicago financial districts as one of the receivers for the Chicago & Milwaukee Electric Railway Co., recently reorganized.

Foreign News

Lens, France—British troops on entering Lens found that the coal mines in the city had been entirely destroyed.

Vancouver, B. C.—During the past few weeks it has been reported that the dealers intended again raising the retail price of coal. This resulted in considerable public agitation which has culminated in the announcement from the former that it is not proposed to advance charges. Instead, they explain, and to offset the increased overhead expenses of handling coal, they have decided to stop the screening of coal in Vancouver. The coal hitherto has received screenings both at the mines and at the dealers' bunkers, the latter operation costing, it is figured, about 20c. a ton. Incidentally the merchants assert that the criticism which has been levelled at them is unfair inasmuch as the mine operators have taken much the greater proportion of recent increases in coal prices. They further state that the same coal as that sold on the lower British Columbia mainland brings from $1.50 to $2 a ton more in Seattle, Wash., while the only extra charge the dealers of the latter city have to contend with is an additional towage fee of 15c. a ton.

Personals

C. C. Anderson, of Boise City, Idaho, has been named as state fuel administrator to succeed Frank E. Gooding, who resigned to become a candidate for state senator.

A. L. Rattray, formerly city clerk at Nanaimo, B. C., has accepted the position of accountant with the Granby Consolidated Mining, Smelting and Power Co., at its new colliery at Cassidy's near Nanaimo, B. C.

Lloyd Dock, division engineer for the Rochester and Pittsburgh Coal and Iron Co. at Punxsutawney, Penn., has been made chief engineer of the Coal Run Mining Co. and Tide Coal Mining Co. at Indiana, Penn.

J. T. Morris, superintendent of the Stotesbury, W. Va., operation of the E. E. White Coal Co., has resigned to accept the position of general manager of the Pemberton Coal and Coke Co., with headquarters at Affinity, W. Va.

Sheldon Smiley, chief engineer for the Rochester and Pittsburgh Coal and Iron Co. at Indiana, Penn., has resigned that position to take charge of the Pittsburgh, Penn., office of the Wood Engineering and Manufacturing Co., of Chicago, Ill.

James Renney, overman for the past two years at the Reserve mine, operated by the Canadian Western Fuel Co. at Nanaimo, B. C., has resigned his position and gone into business, having taken over the interests of the MacFarlane Wharf Co., Nanaimo, B. C.

James A. Bier has resigned as chief engineer of the Coal Run Mining Co. and the Tide Coal Mining Co., of Indiana, Penn., to become superintendent of the Horatio mines of the Anita Coal Mining Co. at Punxsutawney, Penn.

Francis John has been appointed overman at the Reserve mine of the Canadian Western Fuel Co., Nanaimo, B. C., to succeed James Renney, resigned, as mentioned elsewhere in these columns. Mr. John was tipple boss at the Harewood mines of the Canadian Western Fuel Co.

Obituary

Steve Harding, division engineer for the Jefferson and Clearfield Coal and Iron Co. at Punxsutawney, Penn., died Saturday, Oct. 5, from pneumonia, superinduced by Spanish influenza. Mr. Harding was engineer for several mines in the infected district and probably caught the disease while at work. He was taken to his home in Clarion, Penn., for burial.

Mine Car. M. S. Runsvold, Bisbee, Ariz., 1,276,468. Aug. 20, 1918. Filed Sept. 7, 1917. Serial No. 190,211.

Mining Machine. E. C. Morgan, Morgan Park, Ill., 1,276,249. Aug. 20, 1918. Filed Aug. 15, 1910. Serial No. 577,134.

System of Mining Coal. E. O. Toole, Gary, W. Va., 1,276,952. Aug. 27, 1918. Filed Mar. 16, 1914. Serial No. 824,979.

Mining Drill. J. A. Kaye, Sault Ste. Marie, Ontario, Can., 1,277,220. Aug. 27, 1918. Filed June, 15, 1918. Serial No. 240,152.

Fuel Transfer Mechanism for Stokers. N. E. Gee, Altoona, Penn., 1,276,642. Aug. 20, 1918. Filed Dec. 29, 1913. Serial No. 809,349.

Mining Apparatus. C. J. E. Waxborn, assignor to Jeffrey Manufacturing Co., Columbus, Ohio, 1,276,141. Aug. 20, 1918. Filed Oct. 11, 1912. Serial No. 725,323.

Safety Gate for Mine Shafts. W. H. Finley, assignor Fairmont Mining Machinery Co., Fairmont, W. Va., 1,276,199. Aug. 20, 1918. Filed Feb. 19, 1918. Serial No. 218,054.

Process of Treating Coal. C. H. Smith, assignor to International Coal Products Corporation, Richmond, Va., 1,276,427. Aug. 20, 1918. Filed Jan. 20, 1916. Serial No. 73,106.

Burning Pulverized Fuel. V. Z. Caracristi, assignor Locomotive Pulverized Fuel Co., a corporation of Delaware, 1,274,384. Aug. 6, 1918. Filed Nov. 5, 1913. Serial No. 799,269.

Briquet and Method of Making Same. C. H. Smith, assignor to International Coal Products Corporation, Richmond, Va., 1,276,429. Aug. 20, 1918. Filed Nov. 15, 1916. Serial No. 131,434.

Ignition Tape for Miners' Safety Lamps. F. Fear, A. E. Naldrett and W. C. Nicodemus, assignors to Fred Fear Match Co., Bloomsburg, Penn., 1,275,543. Aug. 13, 1918. Filed Oct. 22, 1915. Serial No. 57,248.

Publications Received

Saving Coal in Boiler Plants. By Henry Kreisinger, Department of the Interior, Bureau of Mines. Technical Paper 205. Illustrated, 24 pp., 6 x 9 inches.

Thirty-first Annual Report of the Bureau of Mines, Mining and Mine Inspection of the State of Missouri. For the year ending, Dec. 31, 1917. Unillustrated; pp. 101; 6 x 9 inches.

Monthly Statement of Coal-Mine Fatalities in the United States, June, 1918. Compiled by Albert H. Fay, Department of the Interior, Bureau of Mines. Unillustrated, 27 pp., 6 x 9 inches.

Trade Catalogs

The Jeffrey Pit-Car Loader. Jeffrey Manufacturing Co., Columbus, Ohio. Bulletin 246. Pp. 8, 6 x 9 in., illustrated. Describes a light, easily portable loading conveyor which performs the most arduous work the loader has to do, resulting in a considerable saving of muscular energy and man power. The use of the loader decreases the cost of obtaining coal.

Industrial News

Centertown, Ohio—The authorized capital of the Centertown Coal Co. has been increased from $160,000 to $250,000.

Jackson, Ky.—The River Side Coal Co. has filed notice of an increase in its capitalization from $10,000 to $30,000 to provide for expansion.

Mechanicsville, N. Y.—William D. Tweedy, 56 Mabbitt St. is considering plans for the reconstruction of a number of coal pockets at his plant.

Russell, Ohio—The No. 6 Coal Co. has been chartered with a capital of $25,000 by D. A. Robinson, J. W. Burnett, B. J. Patch, H. W. Parker and H. A. McAuley.

Hazard, Ky.—The Hazard Coal Co. is having plans prepared for the reconstruction of its power plant recently destroyed by fire, with loss estimated at $5000.

Kilday, Ky.—The J. L. Smith Coal Co., capital $75,000, has been incorporated by J. L. Smith, George F. Noel and J. W. Farmer, and expects to develop coal properties.

Henderson, Ky.—The Charles T. W. Argue Coal Co., Henderson, capital $25,000, has been organized and incorporated by Charles T. W. Argue, W. H. Winstead and F. H. Harrison.

Lexington, Ky.—The Swift Coal and Lumber Co. is said to have acquired additional property in the vicinity of its local holdings, and is planning for early development work.

Houston, Tex.—The Texas Oil, Gas and Mineral Products Co. has been incorporated with a capital of $1,000,000 to develop coal, kaolin and silica deposits in Grimes County. W. C. Munn, Houston, is president.

Centertown, Ky.—The Centertown Coal Co., has filed amended articles increasing its capital stock from $160,000 to a quarter of a million in order to take care of contemplated improvements to increase production.

Chavies, Ky.—The Coneva Coal Co., at Chavies, one of the fast developing eastern Kentucky concerns, has filed amended articles of incorporation in which the capital is increased from $70,000 to $120,000.

Andover, Mass.—The M. T. Stevens & Sons Co. has awarded a contract to the New England Concrete Construction Co., 201 Devonshire St., Boston, for the construction of a new coal pocket at its plant, about 45 x 125 ft.

Chattanooga, Tenn.—The Chattanooga Iron and Coal Corporation is said to be having plans prepared for the immediate reconstruction of the portion of its plant recently damaged by fire, with a loss estimated at $20,000.

Hartland, W. Va.—The Clay County Fuel Co. has filed articles of incorporation with a capital of $100,000 to develop coal properties in Clay County. A. J. Peck, S. A. Moore and A. A. Lilly, all of Charleston, are the incorporators.

Fairmont, W. Va.—The Dawson-Connellsville Collieries Co. has been incorporated with a capital of $120,000 to operate

coal properties in the vicinity of Fairmont. G. G. Wedding, Carl Riggs and W. M. Kennedy are the principal incorporators.

Birmingham, Ala.—The Big Four Coal Co. has been formed with W. M. Holt, J. A. Carr and W. C. Davis as incorporators. The capital stock is $5000, and the company will engage in coal mining operations in this district.

Madisonville, Ky.—The Curtis Coal Co., which recently filed articles of incorporation with a capital of $50,000, is planning for the early development of coal properties in Hopkins County. Ray L. Curtis, of Madisonville, is president.

Washington, D. C.—The United States Government, Bureau of Yards and Docks, has awarded a contract to the Piel Construction Co., Baltimore, Md., for the construction of a new fuel depot at the Government station at Curtis Bay, Md.

Fairmont, W. Va.—The Diamond Coal Co. has been incorporated with a capital of $200,000 to engage in the development of coal properties in the Fairmont district. Warder Cresson, A. P. Brady and H. E. Engle are the principal incorporators.

Barbourville, Ky.—The Ideal Horse Creek Coal Co., recently organized, is planning to inaugurate operations at an early date on the development of approximately 100 acres of coal lands in the Crawfish district of Kentucky. G. D. Bengey is president.

Lansford, Penn.—The Lehigh Coal and Navigation Co. has awarded a contract to Charles H. Schlegel, Mt. Penn, for the construction of 20 new 2½-story, brick miners' residences. Calvin Young, 249 Jameson Place, Reading, is the architect.

Birmingham, Ala.—The Carbon Hill Consolidated Coal Co., of Carbon Hill, Walker County, has been incorporated with capital of $5000. The company was formed by S. R. Fowler and others, and will engage in mining operations in the vicinity of Carbon Hill.

South Bethlehem, Penn.—The Philadelphia & Reading Railroad Co. is taking bids for the construction of a new coaling station and pits in connection with other improvements at its yards at Saucon Creek. The new station will be of reinforced-concrete and steel.

Buckhorn, Ky.—The Buckhorn Coal and Lumber Co., capital $150,000, has filed amendment to its charter in which the capital stock is increased from $150,000 to $250,000 in order to develop properties and make contemplated improvements to increase production.

Memphis, Tenn.—The Memphis Gas and Electric Co. is planning to commence work at an early date on the construction of a new local coal and coke plant, to include a battery of 27 coke ovens, a number of concrete buildings, scrubber house and auxiliary structures.

New Waterford, Ohio.—The Canton Coal Co. has commenced work on the sinking of a new shaft at its local properties to provide for increased operations. Plans have also been prepared for the construction of a new power house at the plant for operation. J. E. Morgret is general manager.

Charleston, W. Va.—The Columbia Coal Co. has been incorporated with a capital of $90,000 to engage in the operation of coal mines in the Charleston field. C. H. Hetzel, Charleston; Charles A. Smith, Chillicothe, Ohio, and Herbert Hannigan, Lexington, Ohio, are the incorporators.

Clay, W. Va.—The Jones-Winifrede Coal Co., whose land is located at Hartland, in the Clay County field, has changed hands, E. E. George and other business men of Philippi having acquired the plant. H. C. Jones, of Logan, was one of those largely interested in the Clay County operation.

Charleston, W. Va.—The Burning Creek Coal Co., of Kermit, W. Va., has been chartered to operate mines in Mingo County. The capital stock is $10,000. Incorporators are: B. R. Bias, C. G. Bias and J. G. Nesbitt, of Williamson; G. R. C. Wiles, of Charleston, and Harry J. Jones, of Kermit.

Chicago, Ill.—The Chicago Pneumatic Tool Co. announces the appointment of A. G. La Pierre as traffic manager and F. O. Southbrook, as manager of the order and production department. The headquarters will be in the home office of the company, Fisher Building, Chicago.

Huntington, W. Va.—The Winifrede Railroad Co., which is a coal-carrying road operated by the Winifrede Coal Co., has been authorized to increase its freight rates from 15c. to 35c. per ton, according to announcement made by A. H. Land, district representative of the Fuel Administration.

Muskogee, Okla.—The Johnson & King Coal Co., Barnes Building, is planning for the immediate development of approximately 400 acres of coal lands at Clarksville, Ark., to have a daily capacity of about 250 tons. New mining machinery and equipment will be installed. Earl H. Johnson is president and manager.

Lynch, Ky.—The United States Coal and Coke Co., Carnegie Building, Pittsburgh, Penn., will build a 1-story (45 x 60) 132 ft. reinforced concrete bin, 40 ft. high, 20 ft. above ground, 45 ft. wide at a cost of about $100,000. Work will be done by day labor under the supervision of H. N. Eavenson, of Gary, W. Va.

Charleston, W. Va.—The Royalty Coal Co., of Morgantown, W. Va., has been incorporated with a capital stock of $50,000 to operate coal mines in Monongahela County. The incorporators are: Glen Hunter, Morris Clovis, Howard Swisher and Don K. Marchard, of Morgantown, and Jesse E. Moore, of Mooresville.

Charleston, W. Va.—The Equitable Byproducts Co., of Pittsburgh, Penn., has been incorporated with a capital stock of $90,000 to manufacture coke and other coal byproducts within the state of Pennsylvania. R. T. Rossell, Frank J. Young, E. C. McHugh, L. T. Sanders and F. L. Soles, all of Pittsburgh, are the incorporators.

Straven, Ala.—The Montevallo-Straven Coal Co., recently incorporated, has perfected its organization and is planning to commence work at once on the development of about 400 acres of coal properties in the Straven district with an initial capacity of 100 tons, to be increased ultimately to about 400 tons. F. E. Dunlap is president.

Charleston, W. Va.—The Big Six Coal Co., which has been successfully operated on Campbell's Creek, Kanawha County, has changed hands. H. T. Smarr and associates having acquired the holdings of the company from C. W. McNulty and others. Mr. Smarr will act as general manager of the mines acquired by him in the deal.

Columbus, Ohio—The G. C. Silcott Coal Co. has been incorporated with a capital of $25,000 by George C. Silcott, Mary A. Summers, Eva M. Silcott, R. M. Snetzer and D. H. Armstrong. The company succeeds the Silcott Coal Co., and will have larger offices on the ninth floor of the Brunson building. It will do a general jobbing business.

Radnor, W. Va.—The Burk Coal Co., Huntington, W. Va., has been organized to operate holdings in the Radnor district. The company controls the Radnor Coal Co. and the Laurel Creek Coal Co., and is considering plans for the construction of a new tipple and the installation of mining machinery for extensive development. John L. Corcoran is president.

Willard, Ky.—In connection with the extensive improvements planned by the Black Raven Coal Co., a large quantity of new mining machinery including coal-cutting apparatus, electrical equipment, screens, and other equipment will be installed. It is planned to have an ultimate output of approximately 1000 tons of coal daily. W. H. Norris is general manager.

Girdler, Ky.—The Steele & Alder Coal Co., recently incorporated with a capital of $18,000, has arranged plans for the immediate development of approximately 150 acres of coal properties in the vicinity of Girdler, to have an initial capacity of about 30 tons daily. New equipment for operation will be installed. W. B. Steele and Rex E. Steele, both of Pounding Mill, Va. are president and vice president respectively.

Chehalis, Wash.—Twenty-five of the city's most prominent business men held a conference recently for the purpose of interesting capital in the development of a plant for the crushing of coal which is abundant in adjacent fields and using it in powdered form at local industrial institutions. N. B. Coffman, A. C. St. John ad W. A. Shoell are prominent in the movement, as well as President A. Campbell, of the Superior Coal Co.

New York, N. Y.—Among recent contributors to the Coal Trade Liberty Loan Committee quota for the purchase of Liberty Bonds are J. E. Berwind, $150,000; Porto Rico Coal Co., $100,000; New Central Coal Co., $25,000; Weber, McLaughlin Co., $15,000; Gavin Rowe, $10,000; Scranton & Lehigh Coal Co., $117,000; Tuttle's Son & Co., $50,000; Bacon Coal Co., $30,000; Delaware, Lackawanna & Western Coal Co. (additional), $1,000,000; and Wilputte Coke Oven Corporation, $53,050.

Charleston, W. Va.—The Clay County Fuel Co., Kanawha National Bank Building, recently incorporated with a capital of $100,000, is planning to commence work at once on the development of approximately 600 acres of coal properties in the vicinity of Hartland. It is proposed to have an initial capacity of about 100 tons daily. William T. George, Philippi, W. Va., is president; A. A. Lilly, A. J. Peck, and S. A. Moore, all of Charleston, are first vice-president, second vice-president and secretary-treasurer, respectively.

Charleston, W. Va.—The Capital issues Committee has approved an issue of $150,000 of 7 per cent, sinking fund gold notes of the Eagle Byproducts Co., the proceeds of which will be used by the company to provide for extensive improvements and additions at its mines in the Paint Creek district, to increase the present capacity. It is understood that the coal produced by the company is in great demand for byproduct purposes, and the company is understood to be planning to increase the output ultimately to approximately 2000 tons daily.

Denver, Colo.—Arrangements are being rapidly completely by the Delaware holding company of the Western Pacific R. R. of California to legally assume ownership and control of the Utah Fuel Co., of Utah. This is a new and big asset for the stockholders, it having been recently set aside for them by the Denver Federal Court in part payment of their $38,000,000 court-affirmed debt against the Denver & Rio Grande R. R. The Utah Fuel Co. owns 26,000 acres of coal lands, which are estimated to contain 170,000,000 tons of coal. Some 800 coke ovens are now at work on the property.

Cleveland, Ohio—The Elliott Electric Co. has removed from 322-328 Champlain Ave. to 813-815 Superior Ave., N. W., where it occupies the entire five floors and basement. The first floor is occupied by the retail store and supply department office. The second floor is devoted to the general office and the machinery department office. The repair shop for the repairing of motors is located on the fourth floor. The remaining floors and basement are utilized to accommodate the large stock of motors and electrical supplies. The retail store is being remodeled, and when completed will be the largest in Cleveland.

Toledo, Ohio—The movement of coal to the upper lake regions from the Toledo docks is going ahead actively. The vessel movement is generally good and those in charge of the lake trade believe that the quota for the Northwest will be reached before the close of navigation. The Hocking Valley docks during the week ending Oct. 5 handled 188,000 tons as compared with 200,000 tons the previous week, making a total of 3,876,000 tons since the season opened. The Toledo & Ohio Central docks during the same week loaded 92,000 tons as compared with 85,000 tons the previous week, making a total of 1,699,000 tons for the season.

New York, N. Y.—The Anthracite Committee of the United States Fuel Administration has announced the 1918-1919 coal allotments for 1650 communities in the State of New York. The total tonnage in domestic sizes for the state is 15,855,300 tons, which is a 12 per cent. increase over the previous year's distribution figures. New York City gets 8,005,975 tons this year, or 872,567 tons more than during 1916-1917. Up the state there are 239 places which get no anthracite; 1345 towns that receive tonnages ranging up to 15,000 tons; 20 communities get over 15,000 tons; 18 places receive over 25,000 tons; 16 over 50,000 tons and 11 cities receive over 100,000 tons each. Rochester receives 599,865 tons; Buffalo, 599,015 tons; Syracuse, 380,212 tons, and Albany 296,058 tons.

Kansas City, Mo.—The investigation into retail coal dealing in Kansas City, conducted by Gregg & Co., of St. Louis, at the instance of the local dealers, has had incidental benefits, in addition to its usefulness in negotiations with the Fuel Administration. One of these beneficial features is the disclosure of inefficient business methods to some of the dealers. In some cases, for instance, the accountants discovered that dealers were making quite inadequate allowances for overhead; in other cases, the owners of the business were not allowing themselves any salaries. Two or three dealers were making no charge to their coal business, for rent of ground owned by themselves, though such rental charges appeared concerning ground which they leased for their coal purposes. In several instances coal dealers were carrying their property on their books at an antiquated value. There were numerous other such factors disclosed, which had prevented the dealer from figuring accurately and honestly on his costs of doing business.

MARKET DEPARTMENT

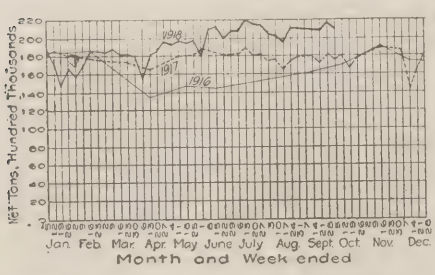
Weekly Review

Soft Coal Output Well Above Weekly Requirements—Anthracite Production Shows Slight Decrease—Labor Shortage and Poor Car Supply in Bituminous Regions—Influenza Epidemic Affects Hard Coal Output—Zoning Restricts Movement of Illinois Coal

REACTING to the drive for greater tonnages now being made by the Production Division of the Federal Fuel Administration, the bituminous mines during the week ended Oct. 5 shipped 12,585,000 net tons of coal. Though this output is a decrease of 462,000 net tons as compared with production the week preceding, the total not only exceeds the weekly requirements of the country by 4 per cent., but helps to make up 3.2 per cent. of the existing soft coal shortage. Anthracite production during the same week totalled 2,052,000 net tons, a decrease of 19,000 net tons as compared with output the week ended Sept. 28.

Labor shortage and poor car supply, the two bugaboos of the soft-coal operator, are again noticeably to the fore in the bituminous regions. The Fairmont district of West Virginia is one of the sections that by a scarcity of cars has been heavily handicapped in its efforts to meet production quotas. As an aside, it may be particularly appropriate to recall that the Railroad Administration not so long since emphatically stated that all mines would receive a 100 per cent. car allotment based on new ratings, and that cars would be moved to and from the mines with maximum speed and efficiency. So much for promises! Other soft coal producing sections, not so unfortunate as far as cars are concerned, complain of a shortage in man power and are troubled by labor that is restive and too prone to holiday-taking. As contrasted with other years, however, the mine workers have responded well to the demands made upon them.

In the anthracite region production is being seriously curtailed by the influenza epidemic. The disease has already necessitated the closing down of several large collieries, and hardly an operation but has a number of its employees on the sick list. It is estimated that daily production is being reduced from 25,000 to 35,000 tons from this cause, and all possible efforts are being made to prevent the further spread of the disease.



The most carping critic must now admit that the Fuel Administration has amply justified its reason for being. In control of all production and distribution facilities, the Administration has brought to fruition the many plans which it formulated early in the year for safeguarding the nation's fuel supply. In the face of apparently insurmountable obstacles and scathing sarcasm from many quarters, Dr. Garfield and his assistants have steadily labored until chaos has given way to order; and it is gratifying to record that New England and a number of other important industrial centers report ample reserve stocks of fuel against the uncertainties of winter mining and shipping conditions.

There is one phase of the distribution system, however, which seems to demand consideration. The mines in the Standard and Mt. Olive fields of Illinois are confronted with a serious predicament. Consumers who receive their coal supply from these fields have stocked up with fuel to such an extent that the mines in these districts now have no market for their product. At the same time parts of Iowa, Nebraska, the western part of Missouri and certain northern sections would gladly purchase Standard or Mt. Olive coal, but unfortunately zone restrictions prevent the movement of Illinois coal to these localities. It would appear as if a readjustment of the zoning regulations insofar as they apply to Illinois coal would prove of advantage not only to the mines affected, but would also enable certain sections of the Middle West to obtain a much-needed coal supply.

Only the premature closing of the Lake season by severe weather will prevent the Northwest from receiving its allotment of 28,000,000 net tons of bituminous coal by way of the Great Lakes. October, according to the Fuel Administration's schedule, is only a 3,500,000-ton month, yet in the period from Oct. 1 to Oct. 7 a total of 1,006,954 net tons of soft coal, not including vessel fuel, was loaded at the lower lake ports. At this rate the entire deficit for the season to date would be wiped out by Nov. 1.

WEEKLY COAL PRODUCTION

The output of bituminous coal during the week ended Oct. 5 decreased 462,000 net tons, or 3.6 per cent. compared with the week preceding, but exceeded production during the week of Oct. 5, 1917 by 1,774,000 net tons, or approximately 16 per cent. Estimates placed production (including lignite and coal made into coke) at 12,585,000 net tons as compared with 13,047,000 net tons during the week ended Sept. 28, and as against 10,811,000 net tons during the corresponding week of 1918. The average production per working day during the current week is estimated at 2,097,000 net tons, 78,000 net tons lower than the daily average during week of Sept. 28, but 295,000 net tons in excess of the daily average of the same week last year. The production during the week of Oct. 5 while considerably lower than the week preceding, exceeded the weekly requirements by 4 per cent. and the weekly requirements to make up the past deficit by 3.2 per cent.

Production of anthracite during the week ended Oct. 5 is estimated at 2,052,000 net tons, a slight decrease compared to the week preceding and the same tonnage as produced during the corresponding week of last year. Daily average is estimated at 342,000 net tons as compared with 338,000 net tons for the coal year to date, and as against 331,000 net tons during the same period of 1917. The total production for the coal year to date is estimated at 53,703,000 net tons, an increase of approximately 2 per cent. over last year.

Shipments of bituminous coal to New England during the week ended Oct. 5 were extremely heavy and exceeded the coal received by New England during the preceding week by 137,339 net tons, or approximately 30 per cent. Preliminary estimates place shipments during the week at 588,105 net tons, of which amount 180,576 net tons was received by rail through the gateways and the balance of 407,529 net tons comprised water shipments. The rail receipts exceeded the previous week's tonnage by 3 per cent. while the increase in tidewater shipments amounted to 47 per cent. all harbors reporting considerable improvement. Rail receipts during the current week, however, fell 15 per cent. below the weekly average of the coal year to date, while tidewater shipments exceeded the weekly average by 18 per cent.

Increased shipments from Baltimore during the week ended Oct. 5 caused total shipments from tidewater harbors to exceed the performance of the week preceding by 36,365 net tons. Shipments from all harbors during the week amounted to 953,158 net tons, of which total New York and Philadelphia shipped 452,091 net tons, Baltimore 117,509 net tons and Hampton Roads 382,748 net tons. Shipments from New York and Philadelphia exceeded the shipments from the same ports during the week ended Sept. 28, while shipments from Hampton Roads fell slightly. Shipments from all ports except Hampton Roads during the current week exceeded the weekly average for the coal year to date, while Hampton Roads fell behind 7 per cent.

Production of beehive coke coal during the week ended Oct. 5 is estimated at 572,000 net tons, a decrease compared with the week preceding of 38,000 net tons, or 6.3 per cent. The average production per working day is estimated at 95,000 net tons as compared with 102,000 net tons during the week ended Sept. 28. The operators of the Connellsville, Greensburg and Latrobe

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended Sept. 14	Sept. 21	Sept. 28	Oct. 5
Bituminous shipments, 123 roads	223,131	223,631	230,376	222,704
Anthracite shipments, 9 roads	40,699	36,859	40,524	38,550

districts of Pennsylvania report production of beehive coke during the week ended Oct. 5 at 376,433 net tons and the operation of their plants at 75.5 per cent. of their full time, as compared with 76.4 per cent. during the week preceding. Shortage of yard labor increased slightly during the week.

Conditions in the byproduct industry changed but little during the week ended Oct. 5 as against the preceding week. The operators in the United States of byproduct ovens report production during the week at 585,216 net tons and the full time operation of their ovens at 91.9 per cent. as compared with 92.2 per cent. during the week preceding; and of total losses of their full time of 8.1 per cent., 1.3 per cent. is attributed to lack of coal, 1.3 per cent. to labor shortage, 4.8 per cent. to repairs to plants and 0.7 per cent. to all other causes.

Material improvement occurred during the week in Kentucky and West Virginia. In the former state the operators attributed the improvement to repaired plants while no reason was given by operators for improvement in the latter state. A decrease in production occurred in Maryland, Minnesota, New York and Tennessee. Shortage of labor limited production in Maryland and New York, and repaired plants in Tennessee, while the operators in Minnesota attributed their limited production to other causes.

BUSINESS OPINIONS

The Iron Age—Pig iron was produced in September at 113,942 tons a day, the highest rate in the history of the industry, representing a gain of 4600 tons a day over that of August. The September total was 3,418,270 tons, against 3,389,585 tons in August. Yet 14 furnaces blew out last month and seven blew in, making a net loss of seven. The total in blast Oct. 1 was 365. Ferromanganese and spiegeleisen production went above 66,000 tons last month, or about 12,000 tons more than the best previous record. The manganese situation is easing beyond expectation.

Dry Goods Economist—Dry goods business at retail is above normal in many centers, despite the handicaps caused by the spread of influenza and the fact that merchants everywhere are striving to boom the Liberty Loan, in some cases devoting their entire advertising space to the drive. The Government's cotton crop estimate as revised this week indicates a total yield of 11,818,000 bales, a gain of 681,000 bales over the last previous estimate. The increase is attributed entirely to favorable weather in the cotton belt. Prices of raw cotton continue to recede slowly.

American Wool and Cotton Reporter—Wool is arriving all the time at the Boston market from South America and South Africa, and is being put through the Government "machine" as rapidly as possible. Facilities for transporting wool from the wharf to its destination are not very good. Many mills have run out of civilian orders. Others would like to get wool for civilian purposes but are unable to do so because they are not on Government work. Some mills are running with only 60 per cent. of their operatives on account of the influenza epidemic. There has been perhaps a little more buying of cotton on the part of the mills since the decline in prices, but this has been slight.

Bradstreet's — Cumulatively, favorable war news has stimulated the bond market, raised the levels of peace stocks, and begotten false peace sentiment, against which the President has issued a caution. Peace talk, too, has had some effect on trade, which reflects some hesitation, and the pace of industry has slackened, but some responsibility for this is credited to the country-wide epidemic of influenza, which has hampered industry, resulted in the promulgation of health regulations, the closing of some theaters and schools, and finally in restricted buying by the ultimate consumer. The Liberty Loan campaign also has diverted attention from trading, and pleas for peace emanating from the central European belligerents have brought on a more cautious attitude among buyers.

Atlantic Seaboard

BOSTON

Receipts both all-rail and by water still further reduced. Several modern colliers withdrawn from coastwise service. Nothing but light shipments in prospect. Hampton Roads detention less severe, due partly to fewer arrivals. Bulk of Pocahontas output still moving for line and byproduct use. Meanwhile, long lists are issued laying embargoes against plants served both all-rail and from tidewater distributing points. Condition works hardship on regular shippers. Increased shipments overseas in evidence. Baltimore loadings diminish. South Amboy embargoed for a time and only a light tonnage dumped over the Philadelphia piers. Anthracite receipts, both domestic and steam sizes, also diminish. Storrow anthracite comes forward irregularly.

Bituminous—Shipments generally have shown a notable falling off the past fortnight. All-rail receipts, as compared with a month ago, are on the average 20 per cent less, or approximately 150 cars less daily at the five gateways. For the first eight days of October the average number of cars passing was but little over 600 per day, railroad fuel included. Movement of the latter has somewhat increased, so that the reduction in commercial receipts all-rail is greater than 20 per cent. Not only have embargoes been liberally applied against New England consignees, but the latter of their own motion are shutting off deliveries on contracts that were entered into early in the season. The scarcity of labor to unload cars, the difficulty of adding to stocks already piled high, and further the knowledge that coal is now relatively easy to get are all factors in the current situation. New England has practically a four months' reserve, and now that current requirements can be had the all-rail buyers in particular are disposed to look upon fuel needs the coming winter as a problem already solved. Certainly, if we reach Nov. 15 without shipments being cut down too radically this complacent attitude will be amply justified.

The recent withdrawal of several large modern colliers has shown the trade how quickly it is possible for a reaction to set in. It has long been anticipated that for volume shipments abroad it would be necessary to use still more of our fast self-trimming steamers for overseas work, replacing them so far as possible with old type of slow-going boats that would have small chance of escape in submarine zones on the other side. It is understood that shipments must now begin to increase very fast to meet urgent needs in France, Italy and other allied countries, but not until lately was it thought prudent to deprive New England of the coal such a move would mean.

It is a time, however, when deliveries can be diminished with entire safety, although from the standpoint of New England and the flow of coal to tidewater, especially at Hampton Roads, will have to be followed more closely than a few weeks ago was thought would be necessary. The fact that the very largest consumers, the railroads and other utilities, have less in reserve than the average of the industries, will make it very important to see that there is no protracted breaking down in loading at the Virginia terminals. The extent to which receipts here fall off the next month will be interesting to observe.

Dispatch has improved at Hampton Roads. Where a week ago it was taking four to eight days to load bottoms, the average detention is now down to two days, and in some cases less. One day at Lamberts Point the proportion of coal available to boats waiting was about 40,000 to 90,000 tons, a better showing than had been the case for several weeks. The situation will probably show further improvement as there are fewer arrivals. The withdrawal of so many colliers from the coastwise service will mean a considerable reduction in the number of bottoms to load, from week to week. Byproducts requirements will of course continue heavy, and the large tonnage of Pocahontas and other coals moving west, along the line, and for other purposes will mean a large decrease in the tonnage handled over the piers.

While these factors will operate to reduce shipments here the fuel authorities are busy drawing up lists of consignees to whom further shipments should be discontinued. Not only does this apply against coal routed all-rail, but similar lists filed with shippers and forwarders who have both coal and facilities for deliveries inland. In several cases the result has been a distinct hardship to the agencies concerned. There are instances where shippers having their coal forwarded via the New York piers in regular course were not only obliged to move the coal later via Baltimore but were forced to stand heavy requisitions against it in favor of the New England Fuel Administrator, for distribution as the latter elected. The shipper had contracts outstanding with New England consignees who from time to time have been persuaded to take on coal shipped by the New England Fuel Administrator up to a point where the latter decided no further coal should go forward. For the same reason the fuel authorities cease to have coal at Baltimore or elsewhere requisitioned in their favor. The result is that the regular shipper now has his coal on his hands. His customers with whom he has contracts are not permitted to take coal from him, and as to the ultimate disposition of such cargoes as have arrived or are in transit the New England Fuel Administrator is without helpful advice. In other words, the shipper has his coal withheld from him while there is a ready market, but after fuel is no longer in urgent request and arbitrary stock limits are clamped on he is told he may have his coal for such distribution as may be acceptable to the Fuel Administration. When it is urged in some quarters that the game has been played with great skill, the average shipper is in position to answer, "Yes, but you had all the trumps."

Baltimore loadings have sloped off for New England, but there as elsewhere there is in evidence an increased volume of coal for naval and oversea use. The movement to South Amboy was so heavy a week or so ago that further shipments were embargoed to relieve congestion. The same thing was true of the Philadelphia piers, where the recent withdrawal of Reading barges to load at Port Reading rather than at Port Richmond has made a distinct difference. The port of Philadelphia will from now out show a notable falling off in coal clearances.

Anthracite—There is a further sag in the receipts of domestic sizes. In this respect the 50 cars daily of "Storrow anthracite" seem not to mean any increase in deliveries. Apparently this "free" coal is being used mostly to make up arrears of "independent" shippers, usually at the expense of retailers who depend upon the companies who have proved the more reliable sources of supply. The volume of steam sizes has fallen off very largely, due doubtless to the easy situation with regard to bituminous.

The "50 cars daily" of Storrow anthracite come forward more or less irregularly, and are subject to the same discount in actual shipments that has been true of similar arrangements for bituminous. It is hard to get accurate data, for up to the present writing no statement has been given out.

NEW YORK

Anthracite situation active, but domestic sizes are scarce and in heavy demand. Dumpings decrease owing to New Jersey explosion. Dealers must deliver more egg and pea to take place of stove and chestnut. Shipments to New England to be hurried. Bituminous situation easy, with commercial coals in good shape. Railroads continue to take fuel.

Anthracite—The situation continues active, with domestic sizes scarce and the demand heavy. Dealers report that there has been no let-up in the call for fuel and that the outlook is one of continual activity throughout the winter.

Shipments here fail to show an increase consistent with the demand. On the contrary the dumpings for the week closing Oct. 11 show a heavy decrease as compared with the previous week, not altogether the failure of shippers, but because of the disastrous TNT explosions at Morgan, N. J., on Oct. 5, not far from the coal piers and which interrupted work at South Amboy for two days because the workers could not be reassembled. During the period of seven days there were 5154 cars of anthracite dumped at the various piers, a falling off of 1403 cars from the previous week. The local trade as well as the nearby New England trade were seriously affected by the lack of shipments, but hopes to be able to make it up by increased tonnages which must be sent here if the allotment is to be maintained.

Acting upon the advice of Fuel Administrator Storrow of New England, the Anthracite Committee has requested producers and distributors to see to it that various communities in Massachusetts that receive the larger part of their fuel by water shall receive it by Dec. 1 and that weekly reports be sent to the committee by the shippers showing what progress has been made in that direction.

New efforts to conserve fuel are being announced almost daily by State Fuel Administrator Cooke. Dealers have been instructed to restrict sales to those living outside of communities who either have standing or cut wood available for fuel purposes. Mr. Cooke has also announced that in view of the demands of the War Department for stove and chestnut coal for use in camps and cantonments retailers will have to supply their customers with larger proportions of egg and pea coal.

Dealers continue to receive a larger supply of broken than usual to take the place

of egg and stove. The supply of the sizes below pea steadily increases and there has been some cutting of prices by individuals. The companies are taking advantage of the situation to send some to the storage yards.

Current quotations, per gross ton, f.o.b. tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$6.75	$7.50	Buck	$5.10	$5.90
Egg	6.65	7.40	Rice	4.65	5.10
Stove	6.90	7.65	Barley	4.15	4.30
Chestnut	7.00	7.75	Boiler	4.60	
Pea	5.50	6.25			

Bituminous—The bituminous situation is easy, with plenty of commercial coal here to meet all current needs. Receipts have been below the average but there has been no anxiety on that account.

At the local piers there were 5507 cars of bituminous dumped during the week ending Oct. 11 as compared with 6666 cars the previous week, a decrease of 1159 cars. Much of this shortage was, however, due to the discontinuance of operations at the South Amboy piers on Oct. 5 and 6, because of the New Jersey explosions.

For the week ending Sept. 28 there was a considerable decrease of shipments of bituminous coal to New England from this harbor, Government statistics showing a falling off of 14.8 per cent. as compared with the preceding week. However, shipments to all points increased 4 per cent. over the previous week.

Some results of the application of the Government "lightless" night order have been announced. One of the electric light companies operating in Brooklyn reports having saved 6300 tons of coal as the result of the 184 lightless nights since the order went into effect.

The railroads continue to take coal for their needs, but according to some shippers are not paying the bills promptly. Considerable inconvenience has been caused by the action of the railroads on account of the seizure of the coal, consumers who were in urgent need of fuel having been made to hustle in the open market for coal.

Locally the situation is all that can be desired. There is plenty of commercial coals to meet all necessary needs but no surplus for outside calls. Bunker fuel is comparatively easy with enough to take care of demands.

Current quotations, based on Government prices at the mines, net ton, f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite activity shows no abatement. Dealers deliver short orders. Efforts to move egg and pea. Tonnage below expectations. Full quota assured, but epidemic causes decrease. Good preparation. Steam coals begin to regain strength. No demand for culm. Bituminous in good supply. Coal well distributed. Big plants still embargoed.

Anthracite.—The cool weather brought unusual demands upon the dealers, but by following the suggestions of the local fuel administration considerable headway was made in supplying homes that had no coal. With the increasing severity of the influenza epidemic homes in which there was sickness were given preference, and in many cases where dealers had short supplies the delivery of fractions of tons was resorted to for the first time in many months. This week finds the market unusually short of stove and chestnut, and where any stocks exist they are invariably egg and pea coal. The public shows little tendency to take any but the preferred sizes. In order to change this situation as much as possible Mr. Lewis has just furnished every dealer with a placard calling the attention of the public to the shortage of stove and nut and stating that they are being consigned to the army cantonments, etc. The public is appealed to to use as a substitute a mixture of 60 per cent. egg and 40 per cent. pea. A list of instructions as to how to burn this combination in any heating apparatus is also supplied, and the dealers are expected to induce their customers to change their orders to move these two laggard sizes at this time. Those who call at the dealers' yards are impressed with the official appeal and realize the seriousness of the situation, but as most of the buyers beg for their coal over the telephone the dealers are having much trouble with this class. For this reason it is hoped the fuel administration will use the daily press to help educate the public as to conditions.

The largest shipping company which was compelled to neglect this market last month is consigning much more coal here now. As a whole the tonnage coming into Philadelphia so far this month has been disappointing. The heavy consignments promised to the suburban dealers, who were to have an increase of 10 per cent. immediately, are also much below expectations.

There is an increasing confidence expressed at the offices of the different shippers that the Philadelphia dealers will receive their full quota based on the 1916-17 estimate, plus the increase allowed by the anthracite distribution committee. Naturally the dealers are all growing anxious and impatient and like the householders want to see the coal. From all we can learn we are satisfied that after Nov. 1 the receipts will be heavy, and that by that time the dealers will be more concerned about getting the coal out of their yards than into them. In fact the labor question is growing so serious that by the time severe weather arrives we expect to see much coal bought at the yards, with the consumer arranging for the delivery as best he can. More coal is stored in the cellars than ever before, but the large class of one-ton buyers for the small homes, who always wait until coal is needed, are sure to have trouble in being supplied.

We have made it a point recently to inspect coal as to its preparation as received from various shippers. From personal observation we are of the belief now, when scarcely a dealer would be critical, that coal is coming to market in better shape than in normal times. It is quite true that the larger companies are particularly careful.

The closing of the churches, schools, theatres, etc., on account of the influenza epidemic has been the means of saving much fuel this week, as the weather has been so cool that heating of such buildings would have been necessary.

There is a noticeable bracing in the steam coal market. As a matter of fact the break of a week or ten days since was only felt by the larger shippers. These concerns actually ran into storage yards a considerable tonnage of the sizes below buckwheat. While the market even now cannot be said to have regained its former vitality, still there is a quick market for all of the buckwheat coal that is coming out and almost as much can be said of rice coal. With the sizes smaller than rice there is still a considerable tendency to slackness, but it is thought from now on this will gradually wear away until an active demand is in evidence for every size, with the possible exception of culm. This latter material has not shown any tendency yet to become in active demand. Even with the biggest shippers there is only a stray car called for, mostly in the way of a test by some concern which has not yet tried it. The exemption ruling as to buckwheat has again been placed by the fuel authorities, and it is doubtful whether it will be lifted now until the season is well advanced toward spring.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—There is a growing feeling that the bituminous situation is being mastered. At any rate every plant seems now to be getting along without a great deal of difficulty in procuring supplies and most of them are even able to accumulate a little stock, which is the condition being striven for by the distribution committee. Practically all of the big users which had succeeded in getting stocks of 60 days or more in advance are still being embargoed until they reach a 30-day minimum, when they will again be allowed to receive coal.

BALTIMORE

Influenza demoralizes all lines of business. Soft coal continues easy but of poor grade. No relief, despite urgent call, in regard to anthracite.

Bituminous—There is hardly a coal office in Baltimore that has not been hit by the influenza epidemic. All lines of business are more or less demoralized in a city that for days showed from 1500 to 2500 new cases of the disease a day, and a death list of around 100 daily from influenza and pneumonia. The supply of soft coal continues easy here. The main run continues in box-cars, and despite the big meeting in western Maryland recently in the interest of cleaner coal from that section, as well as from West Virginia and western Pennsylvania, in only one line of movement, coal for loading for eastern shore of Maryland points, was any improvement in grade to be noted. The poor run of soft coal is shown in the fact that the fuel administration here has been unable to get even a fair grade of bituminous for the domestic trade, which had been generally advised to push a high class lump soft coal as a substitute for the anthracite that has not arrived.

Anthracite—Baltimore is still in the throes of disappointment as to any possibility of adequate hard coal supply. There is apparently little hope of immediate improvement, and all the appeals of the city to Washington, backed by facts to show that thousands of homes here are entirely out of coal and have no prospect of getting even a little before real winter comes, have fallen on deaf ears, as far as results go. The fuel administrator of Maryland and the chairman of the city committee spent some time in Philadelphia this week in an effort to rustle up a little coal, having been informed that some mining connections with headquarters there were unable to understand why Baltimore was so desperately short when New York is reported fairly well supplied, at least in some boroughs. Philadelphia has enough to meet early requirements, and Washington dealers in some cases have actually been asking that shipments be held up a time as they could not handle all the coal coming through. The statement, therefore, that Baltimore is estimated to have between 30,000 and 40,000 homes entirely without coal, with more than 200,000 tons of undelivered orders on the books and a big tonnage asking recognition here, is hard of understanding. Many of the yards here were without a pound of coal last week, and some dealers had received no coal for a week or more, and then only small amounts.

Lake Markets

PITTSBURGH

Car supplies sufficient, production being limited by labor performance. Low sulphur specifications.

After attending a conference in Washington of the fuel production managers, R. W. Gardiner, production manager for the Pittsburgh district, states that there has been a sufficient car supply for two months past and that the matter of coal production is one of getting the miners to work harder. Fully 20 per cent. of the men employed in the coal industry have enlisted or been drafted, and those who are left must work harder. Much difficulty has been encountered in getting men to work full time, and to work immediately after pay day.

Production of the Pittsburgh district continues on the increase, with car shortages reported only occasionally, but with labor shortage in evidence almost everywhere. Lake shipments are fairly heavy and with the rerouting of vessels to the "fast docks" recently decided upon the full complement of lake shipments may be reached, but only by continuing the movement to the end of the navigation season. Essential industries are well supplied, but there is still no opportunity to stock.

A movement has started among coal operators to increase the limit on low sulphur coal from 0.05 to 0.06 per cent., and this meets with opposition of the steel producers as they have difficulty in meeting the low sulphur requirements in certain government contracts.

Coal jobbers are doing scarcely any business, as consumers who would be allowed coal are generally taken care of by the Fuel Administration; and the zone system greatly restricts the opportunity of jobbers to act. The market remains quotable at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, with 15c. brokerage allowed to be charged in addition by recognized brokers.

Recently the local fuel administrator called upon the local distribution manager for 450 carloads of coal weekly additional for retail dealers. As the coal could not be found except by taking it from lake shipments, the matter was put up to the Washington authorities, and as a result of an investigation by a field representa-

tive permission has been given to divert 200 carloads weekly. It is expected that this will take care of the matter temporarily, with the larger supply in prospect when the lake seasons ends.

BUFFALO

Bituminous growing easier. Anthracite not so plenty. Authorities claim that it is sufficient. October more favorable than September.

Bituminous — The trade goes on much the same, though the complaint of shortage is mostly from consumers who have suddenly been deprived of their supply by priority orders. As soon as any concern which has been receiving coal regularly finds it sent to someone else, he sends out complaints to all who are in authority and usually succeeds in getting shipments again. It would seem that a more even distribution would save a large amount of turmoil and complaint. As the output is steadily reported as a good percentage over last year, it would seem to need a very severe winter to produce a famine.

Reports from Canada are conflicting. If a consumer or a town is short it seems to be the practice to claim that the shortage is general, but a well-known dealer of Montreal now in Buffalo says that the situation is easy in his territory. A month or more ago he complained of shortage. At the same time all districts will take all the coal they can get. Recent trips through the state eastward and northward find a pretty good supply in the yards of consumers.

Bituminous jobbers are not generally increasing their business. A few are doing pretty well, while most of them are merely waiting for old conditions to return. There must be a surplus of coal before the middleman is active, and that may be far away. There is complaint that the authorities have made vague promises to help them, but are allowing the trade to fall into the hands of the zone distributors.

Prices, as prescribed by the Fuel Administration, remain at $4.65 for thin vein Allegheny, all sizes, $4.45 for Pittsburgh lump, $4.20 for Pittsburgh mine-run and slack, all veins, $5.85 for smithing and smokeless, $5.60 to $6.10 for cannel, all per net ton, f.o.b. Buffalo.

Anthracite—The complaint of increased shortage through the city continues. In all instances where requests were for coal to be sent to families having the influenza the supply was sent promptly. So it is hard to say whether the city really is badly off or not, though practically every dealer will say so. It will take actual cold weather to determine that.

The list of cargoes loaded to the lake trade shows a number of ports which commonly receive only a single cargo a season, in which case there is usually no freight rate, the coal being bought here by the consignee. The amount for the week is large—122,200 tons—of which 35,800 tons cleared for Duluth and Superior, 31,300 tons for Milwaukee, 16,000 tons for Fort William, 10,100 tons for Chicago, 7200 tons for Ashland, 6400 tons for Escanaba, 6000 tons for Port Arthur, 3200 tons for Racine, 3000 tons for Sheboygan, 1800 tons for Kenosha and 450 tons for Saugatuck.

Freight rates continue at $1 to Racine and Kenosha, 60-65c. to Chicago, 55c. to Milwaukee, 50c. to Sheboygan, 48c. to Duluth, Ashland, Fort Williams and Port Arthur.

CLEVELAND

Withdrawal of all Baltimore & Ohio cars from Ohio coal mines and their transfer for use from the Fairmont field of West Virginia to tidewater is the outstanding feature of the coal situation here. Other roads are seeking to plug up the hole, but the loss in tonnage, especially to the lakes, will be distinctly felt. Labor continues the limiting factor, generally. Coal for domestic purposes has been a trifle more free.

Bituminous—Official notice that the Baltimore & Ohio R.R. would supply no coal cars to Ohio mines in the last half of the week ended Oct. 12 put a decided damper upon the industry. The lake trade is the greatest sufferer, though car supply on the other lines has been increased as much as possible to fill the gap. But even with this loss, car supply is less a limiting factor than labor. Industrial consumers are getting a trifle less coal than they were a week ago, while the domestic trade is benefiting. As against 15 to 20 per cent. of its needs, the retail trade is getting 30 to 40. for the time being.

Anthracite—Occasionally a small lot of anthracite filters through the blockade the zoning system has been put into effect, but receipts for the domestic trade may be said to be negligible. Complaint still is heard from upper lake dock operators to the effect that their quota of anthracite is far from filled.

Lake Trade—Only some unforeseen contingency, such as an early closing of the lake season by a premature winter, can keep the Northwest from getting its desired 28,000,000 tons of bituminous via the Great Lakes, is the consensus of opinion of the better-informed lake coal shippers. October, for example, is only a 3,500,000-ton month according to the Federal Fuel Administration's schedule, yet in the period of Oct. 1-7 a total of 1,006,954 tons of bituminous, not including vessel fuel, was loaded at lower lake ports. At this rate the entire deficit for the season to date would be wiped out by Nov. 1. Operators further point out that no shipments at all are scheduled for December, while in December, 1917, the lake fleet took up more than 660,000 tons. Oct. 9 proved to be the biggest coal-loading day of this season, when a total of 4401 cars, or 219,500 tons was loaded. Diversion of coal cargoes at the head of the lakes from slow to fast dock continues, and complaints of operators against this precedure are decidedly softened.

DETROIT

Efforts to supply the needs of domestic consumers hold the attention of dealers. Speeding of anthracite is promised. Lake trade continues heavy.

Bituminous—Detroit's supply of bituminous suitable for household use is not being increased to the extent that dealers expected it would be from the recent change in regulations governing zone shipments. The explanation is offered by jobbers that domestic lump and other prepared sizes, owing to priority orders, are finding their way into the lake trade.

The change in zone shipping withholds from Detroit and the entire lower peninsula of Michigan the product of mines in Ohio, West Virginia and Kentucky, except when delivery is made for the use of domestic consumers, gas companies, railroads and byproduct plants. This regulation cuts off shipments from the southern fields to industrial and manufacturing plants, and incidentally deprives Detroit jobbers of a large proportion of their trade by taking away their source of supply.

The manufacturing and industrial plants are authorized to provide for their coal requirements by obtaining coal from mines in Indiana and Illinois. Coal from those districts is regarded by many of the local consumers of steam coal as being of an inferior quality. Jobbers report also they are experiencing difficulty in getting coal from Illinois, and that some of the operators in that district appear unable to take care of the new business.

Anthracite—From J. B. Morrow, of the distribution division of the Federal Fuel Administration, Detroit has received assurance that anthracite shipments will be increased at once and that between 80,000 and 90,000 tons will be delivered within the next 30 days. Mr. Morrow also announces Detroit will receive the full 601,000 tons allotted to the city for the coal year. The light shipments so far received are explained as due to the desire to give precedence to movement of coal over the lake routes during the navigation season. The anthracite shipments promised for the month, according to the state fuel administrator, will practically all be required in filling orders already booked from owners of baseburners.

Lake Trade—Lake shipments of bituminous coal are continuing in good volume at an average a little above 1,000,000 tons a week. Vessel capacity for handling the coal is being supplied promptly.

COLUMBUS

With an increased demand for screenings, the coal trade in Ohio is in better shape than a week ago. There is not an oversupply of screenings and mine-run on the market. Lake and domestic tonnage is selling well.

Recent modifications of the embargo against shipping anything except lump coal into Michigan have had the effect of relieving the fine coal situation in Ohio. For several weeks there was an oversupply of screenings, and limits on storage to Ohio consumers were lifted. But the latest modification is to include all of southeastern Michigan in the territory to which screenings can be shipped. As a result there is no oversupply available and the steam market is again about normal. Manufacturing plants are still in the market for a considerable tonnage of fine coal. Public service concerns are well supplied and public institutions are also looked after. Indications point to a steady steam trade for the immediate future.

The domestic trade is also rather active. Dealers are taking time by the forelock, so to speak, and are stocking up for the first cold snap. Retail stocks are fairly large. Some of the dealers are enlarging their storage space in order to be in a better position when the low temperatures arrive. Orders are not plentiful, as fully 75 per cent. of the domestic coal required in central Ohio has been stored by the householder. Retail prices are firm at the levels which have prevailed for some time. Pocahontas is not to be had and there is only a small amount of anthracite available. Pomeroy Bend and the Hocking Valley are supplying the greater part of the domestic tonnage.

Production is slightly increased in most of the Ohio fields, although there is considerable car shortage reported. The lack of cars is most noticeable on the Toledo & Ohio Central and Kanawha & Michigan. Motive power is scarce, and that is the principal reason for failure of empties to arrive at the mines. The Hocking Valley Ry. is now receiving locomotives ordered almost a year ago, and some of the U. S. A. locomotives are diverted to other lines. In eastern Ohio there is still a marked labor shortage which is curtailing the output. Generally speaking, the output is estimated at about 75 per cent. during the past week.

The lake trade is being pushed as rapidly as possible. The vessel movement is active and little time is lost at either end of the journey. Indications point to a complete filling of the requirements of the Northwest before the closing of navigation.

CINCINNATI

Strong demand in all departments. Supply as good as at any recent time, and increasing consumption for heating is noted.

With some raw and cold weather as a further stimulus to consumption in this vicinity, there has been no opportunity for a let-up in the demand for fuel lately, especially in view of the well-advertised conviction of some high authorities that there is not going to be enough coal to go around when the severe weather arrives. With this belief firmly impressed upon the public in general, including the numerous manufacturing concerns which have been unable to secure rating as essential industries, entitling them to a regular supply of fuel under a priority order, it is natural that demand should continue from all quarters at a high rate. Efforts are still being made by manufacturers who have not received priority rating to secure such rating from the authorities at Washington, but there are extremely few instances where such efforts have been successful. The result has been that arrangements for the storage of a larger supply of coal than ever before are being made by these manufacturers, in order to enable them to tide over anticipated periods of shortage without the necessity of suspending operations. Retailers are in the market for about all the coal they can secure, as the cooler weather has produced the usual crop of one-ton orders, and the average dealer is still occupied in making deliveries on orders booked some time ago for fall and winter delivery. The danger of a domestic shortage locally is rapidly diminishing as these deliveries are made, and is not now considered serious.

LOUISVILLE

Domestic coal in better supply, demand little weaker. New regulations allowing stocking of screenings by industrial consumers are aiding situation materially. Operations on much better basis of production.

Lump coal is coming in from the mines in much better quantities than it has, and some of the retailers are again stocking a little surplus of western Kentucky lump, as the demand is not so keen as it has been. All deliveries of eastern Kentucky domestic sizes are being cleaned up as rapidly as received at the present time. The steam demand is generally good, but hasn't been up to production under old regulations.

Wiley B. Bryan, Federal Fuel Administrator for Kentucky, during the week announced that effective at once, the order of Aug. 26, limiting the amount of eastern Kentucky coal stored by public utilities, has been modified as follows: "All restrictions covering the storage of slack and screenings from the eastern Kentucky fields have been withdrawn. This does not apply to the storage of mine-run or prepared sizes of coal from eastern Kentucky, restrictions on which will prevail as cited in the order of Aug. 26. All restrictions are removed covering the storage of coal by industrial or other consumers of all grades of coal mined in western Kentucky." The order of Aug. 26 limited the amount of storage of eastern Kentucky coal by public utilities to a 30-day supply; by preferred industries to 20 days, and non-preferred industries to 15 days. The order permitted the use of only

screenings or mine-run from western Kentucky for current necessities as a condition of retaining reserve stocks of eastern Kentucky coal.

Under the new regulations the operators will be enabled to dispose of all screenings with dispatch. Under the old regulations many of the eastern Kentucky producers had about quit loading out lump coal, as they had no market for screenings. Many had had considerable trouble in disposing of screenings, and preferred shiping nothing but mine-run, which could not be utilized to advantage by retailers unless they had screening facilities.

BIRMINGHAM

Coal trade in this district continues firm. Steam is fairly easy, while domestic demand does not seem to have lost any strength. Production still badly off. Car supply ample in most cases to move all coal mined without delay or interruptions.

The local market, so far as steam grades go, is comparatively easy, some reports indicating a slightly stiffer demand than last week. The production and requirements are perhaps nearer a parity now than before at any time this year. The call for domestic grades has slackened little, if any, and receipts are still inadequate to fill orders in the hands of dealers. Yards have been unable to make any progress in accumulating stock piles for the late buyers who, for one reason or another, are not laying in their winter fuel.

The Alabama field hung up another low-production record for the week ending Sept. 28, only 383,067 net tons being mined for this period. Spanish influenza is invading the mining camps now, and if allowed to spread will seriously cripple operations. It is prevalent in the Walker County field and is already hampering the output in that section. Labor is showing little inclination to speed up, and much time is being lost by mine workers without excuses worthy of consideration. Mines report an adequate car supply in most all instances and there has been no loss of time waiting on loading equipment.

Mines on the Warrior River without rail connection are now being afforded some relief by the wooden barges being used temporarily in moving their coal to the Mobile and New Orleans markets. The steel barges are expected to be in commission in the early part of November and ample service on the river will enable a much larger production from these operations on the river or connected by short rail lines.

Coke

CONNELLSVILLE

Large increase in pig iron output attributed partly to improvement in coke quality, much complaint remaining. Coke production practically unchanged.

The report of pig-iron production in September showed even a larger gain over August than was expected, the rate being about 41,900,000 tons a year, for the whole country, against a rate of only 40,300,000 tons in August. While the progress of the season, bringing lower atmospheric humidity, is credited with part of the improvement, a considerable part is probably attributable to the supply of coke of better quality, a matter to which the Fuel Administration has been giving close attention since the end of August. There are practically no reports of coke shortage, but complaint as to quality is still prevalent.

Production of coke in the Connellsville region shows no great change, but has been decreasing slightly the past few weeks, all in favor of more coal being shipped out of the region, however, as the total of coal coked at home and coal shipped to byproduct ovens has increased almost every week. If more coal from other districts can be found to supply to byproduct ovens it will be possible to resume operations at some beehive ovens in the region recently closed.

Screening operations at old dumps have decreased since the recent reduction in the price limit, but several operations are still actively engaged and there is a fair-sized output of this material, which always finds a ready market as household fuel. The market remains quotable at the set limits: Furnace, $6; foundry, 72-hour selected, $7; screened, over ¾-in., $7.30; clean screenings from old dumps, over ½-in., $5.50, all per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Oct. 5 at 330,160 tons, a decrease of 5035 tons.

Buffalo—The trade continues strong, the local by-product plants experiencing considerable difficulty in keeping up their output, on account of the influenza epidemic and the street railway strike. Still there is no complaint from the consumers and the requirement is met somehow. Government prices prevail and govern the by-product output also, on the basis of $7 per net ton for foundry and $6 for foundry at the beehive ovens. Fuel coke is active, jobbers selling all they can get at government prices from $4.84 up.

Middle Western

GENERAL REVIEW

Production keeps up and territory finds it difficult to absorb large tonnage. Screenings and steam sizes weak. Railroad administration practically does away with reconsignment of cars.

For the last three weeks or a month there have been no changes to speak of in the Middle West coal market. Production keeps up under very favorable conditions, and the territory is having a difficult time absorbing the large tonnage produced. Screenings and all steam sizes are weak, and will probably continue so for some time. There is a fair demand for the carefully prepared domestic coals, but it is not as strong as it was during July.

The recent ruling of the Fuel Administration, taking 100 cars per day from the Mississippi Valley, and giving them to the West Virginia and eastern coal fields, is going to be felt, and will eventually strengthen the market. Just how much effect this rule will have on the market will depend entirely upon how long Illinois and Indiana are to be deprived of coal cars for the benefit of the eastern producers. To date, however, the coal carrying equipment forwarded east has had no noticeable effect on either the market or the producers.

A factor which has tended to keep the market weak is a ruling by the Railroad Administration which practically does away with reconsigning. This has caused the coal jobber to buy more cautiously. Instead of purchasing a string of cars to be shipped to a given reconsigning point, and taking a chance on disposing of the coal which is in transit, the jobber now is forced to sell his coal before it is shipped. The result is that the tonnage shipped for the account of various jobbers is falling off to a substantial degree.

Developments of the zone question have turned out as expected, and at the present time Illinois coal will be allowed to move to points within the "summer zone" until further notice. The eventual result will no doubt be that the summer zone will remain for all winter, and probably be enlarged as well. The authorities have taken this step, because in spite of large purchases on the part of a number of railroads the market keeps weak.

CHICAGO

Little interest shown in coal. Domestic coals firm, but retailers do not seem to be adding to their storage piles. Anthracite situation getting worse.

There has been no great strengthening in the Chicago market since last week. On the whole, purchasing agents are little interested in coal. One of the large purchasers has withdrawn from the market, but to counterbalance this a big public utility corporation, with plants in the Northwest, has entered the market, and has purchased practically all the screenings available in the southern Illinois district. Domestic coals of the better grade are firm, but there is no noticeable tendency on the part of the retailers to add to their storage piles. The anthracite situation gets worse from day to day, rather than improves.

MILWAUKEE

Mild weather heading off an impending clamor for coal. Complaint of over-deliveries at the expense of small consumers. Labor scarcity hampers shipments.

Mild, Indian summer weather throughout this section of the Middle West serves to allay to some extent the anxiety of consumers as to fuel supplies for the coming winter, but a storm is bound to break when the freezing period finds thousands of bins bare of coal. To offset the plea of dealers that shortage of help is hampering deliveries, the charge is made that 22 homes on a leading residential street contain an aggregate of 710 tons of coal, while many poor cottagers, who have had their orders in for months, have not received a pound. The matter is to be investigated. The fuel administration office is urging dealers to make deliveries in small lots and authorizes them to suggest any changes in present rules which will facilitate such action. Every effort will be made to avert suffering when real cold weather sets in. Lack of yard help is hindering shipments to interior points. One dock which normally loads 1000 cars per month has been unable to send out more than about 400 cars.

The county authorities have received bids on 500 tons of mine-run steam coal for two public institutions, but no award will be made until samples are given a test.

Cargo receipts for October thus far aggregate 33,271 tons of anthracite and 112,403 tons of bituminous, making the latest revision of the season's receipts 494,709 tons of hard and 2,880,089 tons of soft coal.

ST. LOUIS

The local condition is beginning to get serious on account of no market for Standard and Mt. Olive domestic and steam sizes. Carterville more plentiful and certain large dealers have shut off Carterville shipments on account of domestic demand going to pieces. Country demand easy. Equipment more plentiful and transportation good.

The local situation is one that is receiving serious thought from the operating interests. The last week or two newspaper reports stated that there was going to be a plentiful supply of coal, and a larger tonnage than was anticipated has been put in, which has caused the general public, as well as steam users, to hold up their deliveries, with the result that the retail business is practically at a standstill. Little coal is moving to the retail yards other than that for storage. Steam users who are anticipating putting in storage have stopped, with the result that everything has almost come to a standstill and coal is piling up at the mines in the Standard and Mt. Olive districts. In the course of the next week there may be idle days because of no available market.

In the face of this there is a demand for coal from certain points in Iowa, Nebraska and the north, but on account of zone restrictions these places can receive no Illinois coal. The same pertains to some points in the western part of Missouri, where this coal could move.

The local regulation on the distribution of coal is just as drastic with this surplus as if there was a shortage of 50 per cent. and these restrictions and regulations only have a tendency to demoralize the producing end when they interfere with the distribution end.

The country business on Standard and Mt. Olive coal is pretty well shot to pieces, and there is not much in sight unless the severest kind of weather comes along ahead of time. The mines in the Standard field are plugging along now with plenty of equipment because there is no demand for coal, and transportation has shown considerable improvement. Two-thirds of the field would be idle if the railroad tonnage were withdrawn at this time.

The domestic demand from the Mt. Olive field is better than that from the Standard to outside points, chiefly to Chicago and the north, and some little tonnage from this field is moving to Michigan. There are some reports of a tonnage moving into Canada.

Conditions in the Carterville and Duquoin field have changed little. The car supply is short, but better than it has been. The domestic orders in this field are gradually being caught up with at many mines, although there is far from being a surplus of coal; and this is not likely to occur in this field this winter.

The railroad tonnage continues heavy. As a matter of fact it may be greater now than for some time past because domestic conditions are easier. The tonnage of this coal into St. Louis has been better for the last few weeks than for many months past, and many of the larger retailers have asked the operators to hold up shipments.

New restrictions on retail trade are going into effect, such as the placarding of every car of coal, designating the grade of coal it contains, the licensing of weightmasters, and the stamping of all scale tickets with the grade of coal.

Prevailing market per net ton f.o.b. mines is:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump..	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg..	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut.	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1.....	3.05@3.20	3.05@3.20	.....
No. 2.....	3.05@3.20	3.05@3.20	.....
No. 3.....	3.05@3.20	3.05@3.20	.....
Mine Run..	2.35@2.50	2.35@2.50	2.20@2.30
Screenings..	2.17@2.32	2.17@2.32	1.50@1.60

Special preparation on Carterville is 10 cents extra. Williamson & Franklin Co. rate is $1.10. Other fields 95 cents.

COAL AGE

Volume 14 New York, October 24, 1918 Number 17

Spanish Influenza

By Floyd W. Parsons

WE MUST have the necessary fuel to carry on our tremendous war effort. Perhaps the most serious menace at the present moment is the prevalence of the epidemic known as Spanish influenza, which is now sweeping the country. This disease is causing a reduction in the output of coal in nearly all of our important fields, but in central Pennsylvania the losses in production are greatest, averaging more than 100,000 tons per week. Many mines have been completely closed down, and in other collieries the output has been curtailed 50 per cent.

The strictest kind of preventive measures must be put into effect immediately, or we will be obliged to record industrial losses that will be of as great consequence as a major defeat on the battlefield. The remedy for the scourge lies in the hands of each individual. We can render no greater patriotic service now than to exercise a degree of caution and care surpassing anything we have ever done before.

The present disease is no more Spanish than it is Russian, Swedish or Dutch. It is a byproduct of the war and is undoubtedly due to a scarcity of proper food and a lack of warmth. People who are hungry and cold cannot well resist the inroads of the organism that is the cause of this disease. The present influenza germ is serious because it has become strong and healthy in the under-nourished bodies of the underfed people of Europe.

I am not a doctor and cannot speak with the authority of one versed in medicine. However, *Coal Age* is earnest in its desire to help remove the menace, and high authorities versed in diseases of this kind have furnished us with valuable information. Following are a few suggestions, concerning ways to avoid influenza:

Take one-half teaspoonful of bicarbonate of soda in a glass of cool water on arising in the morning. Spray the nose and throat with a standard spray solution such as is easily obtainable from any physician or at any drug store. Drink plenty of pure water one hour before or two hours after meals. In one or more of the glasses it will not hurt to put one-half teaspoonful of bicarbonate of soda or the juice of an orange or lemon. By all means keep the system in good shape and wholly avoid constipation.

People of low physical resistance due to lack of sleep, or to any kind of excess, present the best medium for the spread of the contagion. Liquors and intoxicants should be avoided because of the reduced physical resistance caused by them. Take exercise in the open air. Walk to the mines if possible and sleep in airy rooms. Remove wet and damp clothing at the earliest moment. Do not expectorate in the mines, for the germ will grow and become dangerous in a dark and damp surrounding. Wash hands before eating and have luncheon buckets and pails washed in scalding water once each day.

Miners should not congregate together in the mines and should stay away from men who are sneezing or suffering with colds. Keep your feet warm; wet feet demand prompt attention.

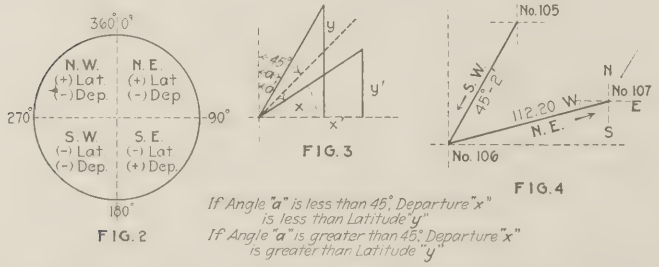
On the first signs of a chill, headache and bone ache, hurry home, and take a hot bath—as hot as you can stand—also a dose of castor oil. Drink hot drinks, preferably hot lemonade, and go to bed. Insist on being placed in a room by yourself and allow only the person nursing you in the room. Keep the windows open but let the room be heated. It has been demonstrated that heat, whether as fire, sunlight or high-temperature water, will destroy the organism.

To avoid pneumonia, which sometimes follows influenza, stay in bed until you are entirely well, and then do not expose yourself outdoors for two or three days after leaving your bed. Ninety per cent. of the pneumonia cases are contracted from arising too soon or from not going to bed immediately after the first chill.

Above all, don't worry. Do your level best to avoid contagion, and remember that by keeping well you are serving not only yourself but your country in its day of dire need.

IDEAS AND SUGGESTIONS

Methods of Tabulating and Computing Latitude and Departure Notes



BY O. H. HAMPSCH
Washington, D. C.

A well-defined method of tabulating and computing latitude and departure notes will be found of considerable value in plotting mine maps and ascertaining the distance between known or given stations. In Fig. 1 is shown a method of keeping notes that may be used in a record book, together with all computations for a ready reference.

The thirteen columns tabulated as shown form a complete record of each station, giving distance, bearing, angle, location, latitude and departure, which should be recorded from some base line or monument as a zero departure if possible. It will be of much convenience in record if the actual computations and figures

1	2	3	4	5	6	7	8	9	10	11	12	13
FROM STA	TO STA	HOR. ∠S TO RT	BEARING	DIST	+ N. LAT.	− S. LAT	+ E. DEP	− W. DEP	TOTAL LAT	TOTAL DEP	REMARKS	STA.
105	106		S16°24'W						−12.163	−243.121	Intersection 4th Entry	106
106	107	42°-1'	N58°25'E	112.20	58.792		95.594		+46.629	+147.527	In 4th left Entry	107

FIG. 1

FIGS. 1 TO 4. METHODS OF TABULATING AND COMPUTING LATITUDE AND DEPARTURE NOTES

can be made on the opposite side of the book—that is, with the record of stations on the left-hand side and computations and figures on right-hand side of the book. This will make it easy for reference to any particular station.

Figs. 2 and 3 are sketches which can be referred to by the computer when in doubt as to the relative sign of the latitude or departure for each quadrant (Fig. 2), and whether the latitude or departure is of the greater value (Fig. 3). Fig. 4 shows a simple sketch the computer may make to indicate the relative position of one station to the other and the direction or bearing each angle makes in reference to the other.

Any method of turning angles may be used, duplication, angles to the right or by quadrants, all of which of course give the same bearing and result. I have used the method of turning all angles to the right from the backsight to the foresight, and column 3, Fig. 1, may be changed from "horizontal angles to the right" to any method that may be used in any particular case.

Is It the Miner or the System?

The average human being is not loath to saddle the brunt of a situation upon an object or person most likely to bear it without retaliation. Following this general rule, the blame for the coal shortage has been thrust upon the miner, "digger," "loader," or whatever many have chosen to call him. He has been made the goat.

Is the miner, however, actually to blame for the coal shortage, or is it the system under which he labors in the average mine? Many mines, it is true, have no system at all, merely being operated according to tradition or supposition.

Despite the fact that many of the mine workers are foreign-born, an injustice is done many of them by baldly stating that they are unpatriotic; that they are un-Americanized. These men are just as human as the operator who employs them, and they will respond readily to the right kind of treatment. The average foreign-born mine worker has been forced down rather than up the social scale.

Suppose you, gentle reader, were a miner toiling in the bowels of the earth, breathing dust and continually risking your life. Could you perform your work if you were sworn at by every boss or sub-boss or other flunky in the mine? If you complained because of the lack of track or timbers or what-not, and somebody told you, "Aw, go to hell and get some," would you feel that you were a good American?

WHY MANY MINERS BECOME DISGRUNTLED

Suppose you loaded a carful of clean coal and then had it stolen by some thief who changed the checks. Would you feel like a good American if somebody laughed at your efforts to explain your troubles? And, if they promised to straighten it out and never did, would you feel like putting in a full day's work every day?

Suppose you told the office that you would need a certain amount of timber and track, so that you could start work early the following morning; and then found when you got to your place that there was nothing to help you make your place safe or rails on which to push the cars. Then suppose you wasted half a day chasing the mine foreman so he could get you fixed up. Wouldn't all of this talk about increased production strike you as being extremely ludicrous?

This condition does not exist in every mine, but it does exist in more mines than any of us have any idea of. Many of our large mines have a sympathetic and progressive management, but there are an appalling number of little fellows who get out a large tonnage as best they can; and by little fellows I do not mean wagon mines. I mean companies whose production runs 100,000 or 200,000 tons a year.

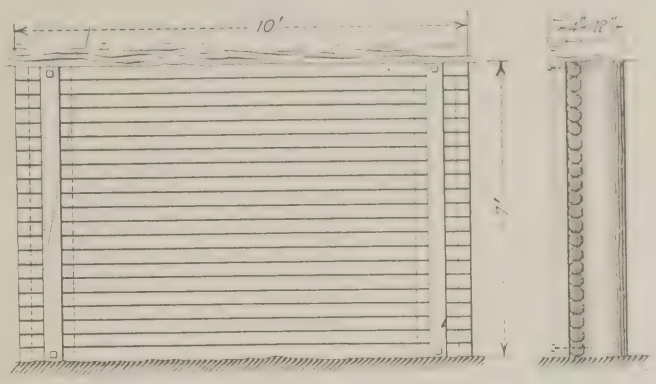
Most of these latter mines have a superintendent and a mine foreman, but these men cannot work efficiently for they have to do all of the "bossing," all of the clerical

work, and look after supplies, purchases, repairs and anything else under the sun. They must listen to the complaints of the daymen, the miners and the higher officials. An angel would give up in despair. As a consequence, they do just as you and I would do, just slide along as best they can and hit the high spots and miss the low spots; and the cleaning out of the "low spots" oftentimes determines the success of a mine or its failure.

Why not let the mine superintendent be a real superintendent? Why make an office boy, a clerk or a rancorous pessimist out of him? Why not fix it so that he can make his mine foreman be a real mine foreman for once in his life? He wants to be efficient and helpful to the miners, but he is so weighed down with his own woes that he justly feels that no one else has a right to unburden himself to him.

Give your foreman enough good helpers to carry out his orders, and then give him the authority to see that they are obeyed. You can hold him responsible, solely responsible, and he will be glad of it; for then he will have a chance to produce results. No man grows quite so fast as the man who is given a chance and is then held responsible for results. All superintendents are held responsible for the production and all foremen are held responsible for the conditions underground, but do they have the right kind of a chance?

The answer is bound to be a negative one, and just so surely is the shortage in desired production to a very large measure directly due to the lack of harmony which is brought about by the overworking and harassing of your first assistants.



It will cost you more money for a while, but for a very short while. In the end you will get greater production; and greater production is needed to back up our boys over there who are battling for humanity's sake, who are battling so that your family and my family will have a decent world to live in.

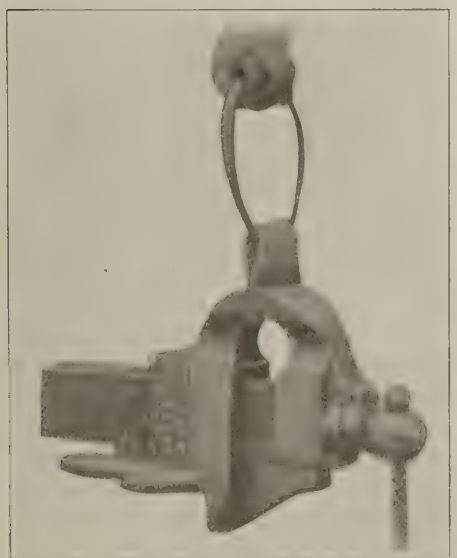
Spikeless Batteries

By Joseph Lawrence
Sugarloaf, Penn.

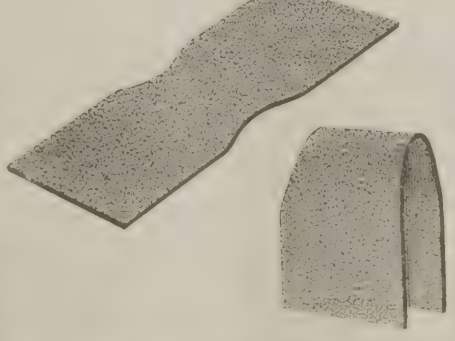
In building batteries in the mines it is customary to construct them of two props to which poles extending transversely are nailed. The props are about 7 ft. long and 12 in. in diameter while the poles are approximately 10 ft. long and 4 in. thick. These poles, 21 in number, are usually fastened to the props at either end with one 60d nail or spike.

The number of spikes used is thus 42 and as each

HOW THE USE OF SPIKES WAS OBVIATED



costs about ½ cent the entire cost for nails is 21 cents. Not only is this expense high but spikes of this size are becoming difficult to obtain.

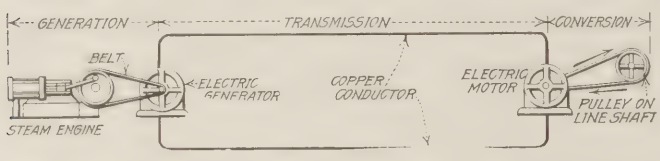


In order to obviate the necessity of using spikes at all I have followed the practice shown in the accompanying illustration. In this construction two extra poles of suitable length are placed parallel with the props and outside of the transverse poles. These outer pieces are held in place by a 12-in. rag spike or drift bolt at either end. These pierce the top and bottom transverse poles and hold them and all the others firmly.

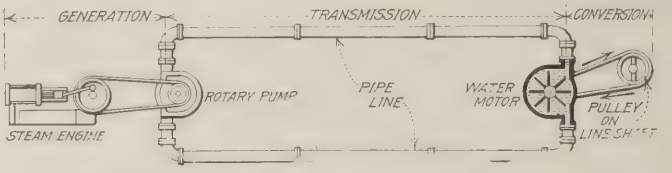
Carrying a Heavy Vise

Two practical suggestions for carrying heavy vises are shown in Figs. 1 and 3. The carrier shown in Fig. 1 consists of a large iron ring on which a piece of rubber tubing is slipped to prevent the ring from cutting into the hand. A piece of leather belting is cut as shown in Fig. 2, folded over the ring and clamped in the vise jaws.

In Fig. 3 a wooden bar of suitable diameter and length is clamped in the vise jaws for carrying purposes. In this last application both hands can be used on very heavy vises. It is simple devices like these that make hard tasks easy.



FIGS. 1 TO 3. TWO SIMPLE SUGGESTIONS FOR CARRYING A HEAVY VISE



Fundamental Relations Between Direct- and Alternating-Current Circuits

By TERRELL CROFT
University City, St. Louis, Mo.

SYNOPSIS — *The theory of electricity is here dealt with. This theory is extremely interesting but requires a somewhat vivid imagination for its comprehension. Fundamental electrical units are also defined, as well as such terms as conductivity and resistivity.*

THE electron theory states that all matter is made up of molecules, of which there are millions of different kinds. Molecules are made up of atoms, of which there are but 92 different varieties; that is, there are but 92 elements now known. All atoms are composed of electrons, which are minute particles of negative electricity held normally in place in each atom by a positively charged something which has been named the "nucleus." The electrons thus interlocked in the atoms are, it is believed, constantly revolving at great speeds in regular circular orbits around the positive nuclei. In this they may be said to resemble the eight satellites which rotate about the planet Saturn. In a normal atom the amount of negative electricity

FIGS. 1 AND 2. AN ELECTRIC (LEFT) AND A HYDRAULIC CIRCUIT (RIGHT) FOR THE TRANSMISSION OF ENERGY

of the electrons is exactly neutralized by an equal amount of opposite or positive electricity of the nucleus. Thus a normal atom exhibits no external sign of electrification. The different kinds of atoms (the elements) differ only in the number of and the arrangement of the electrons and in the magnitude of the positive nuclei which compose them. The lighter elements have few electrons; the heavier elements many. A normal atom of any given element always has the same number of electrons and a positive nucleus of the same magnitude. Hydrogen, it is believed, consists of one electron and a corresponding positive nucleus. Uranium, the heaviest element, has probably 92 electrons and a correspondingly greater positive nucleus.

Thus everything about us, all matter, is composed of electricity. The electrons can, under certain circumstances, be forced from the atoms. The positive nuclei, so it is believed, cannot be moved from the atoms. Electrical phenomena occur when some of this electricity (electrons) is moved or when the electrical balance which normally obtains within the atoms is disturbed.

Electrons are exceedingly small. It is estimated that each has a diameter of about a five million, millionth of a centimeter $\left(\frac{1}{5{,}000{,}000{,}000{,}000}\text{ cm.}\right)$, or about a thirteen million, millionth of an inch $\left(\frac{1}{12{,}700{,}000{,}000{,}000}\text{ in.}\right)$ An electron weighs about one-forty-six billion, billion, billionth of an ounce

$$\left(\frac{1}{46{,}100{,}000{,}000{,}000{,}000{,}000{,}000{,}000{,}000}\text{ oz.}\right)$$

or about a seventeen hundredth $\left(\frac{1}{1700}\right)$ as much as does an atom of hydrogen.

It is evident that there is in the universe a certain definite amount of electricity. Electricity can neither be created nor destroyed. It can, however, be forced to move and thus transmit power or produce electrical phenomena. Electrical energy (not electricity) can be generated by forcing electrons to move through certain paths where it is desired that they should move.

An electromotive force (e.m.f.) is the name given to that tendency or force which makes electrons move or tends to do so. Thus, if an e.m.f. is impressed across the two ends of a wire, it will force the electrons of the atoms to move from atom to atom in the direction of the e.m.f. around in the wire, assuming, of course, that a closed conducting path is provided. A lightning flash is a movement of electrons through the atmosphere caused by an e.m.f. or voltage existing between the clouds and the earth.

An electric current consists of a movement or flow of electrons. Thus that which we call an "electric current" is merely a shifting of these electrons from atom to atom. If an electric current flows in a wire or in anything else, there is, then, a flow of electrons in that wire or thing. The coulomb is the unit of quantity of electricity and is somewhat analogous to our unit of quantity of water—the gallon. A coulomb of electricity comprises approximately five million, million, million (5,000,000,000,000,000,000) electrons.

The ampere is the unit of rate of flow of electricity and is analogous to "gallons per minute" in hydraulics. The ampere represents a rate of flow of one coulomb—that is, five million, million, million electrons—per second. It has been internationally agreed (recommended by the Chicago International Electrical Congress of 1893 and legalized by act of Congress 1894) that the ampere is "that unvarying current, which, when passed through a solution of nitrate of silver in water in accordance with standard specifications, deposits silver at the rate of 0.001118 gram per second."

Resistance is the name given to that opposition which

is offered by the materials to the movement of the electrons—that is, to the flow of an electric current—in them. The electrons of some materials, the metals for example, can be moved from atom to atom within the material with relative ease—that is, by the application of a small e.m.f. The materials in which the electrons can be easily moved from atom to atom are called "conductors." On the other hand, it is difficult to move the electrons from the atoms of other materials, such as air, glass, mica and porcelain. Such materials are called "insulators." However, there is no perfect conductor and no perfect insulator. All materials offer some opposition to the establishment of a current and there is no material in which a current cannot be established provided the impelling e.m.f. is sufficiently great. Witness again the lightning flash.

The ohm is the name given to the unit of electrical resistance. It affords a measure whereby the degree of opposition of the different materials to the establishment of an electric current in them may be measured. Practically speaking, the international ohm "is represented by the resistance offered to an unvarying electric current by a column of mercury at the temperature of melting ice, 106.3 centimeters long and having a cross-sectional area of 1 square millimeter."

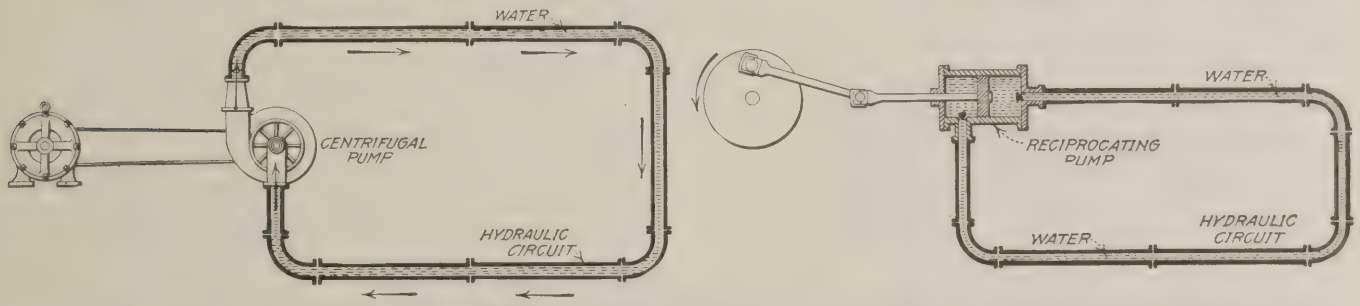
A piece of No. 14 B. & S. gage copper wire of the size ordinarily used for branch wiring in lighting circuits 380 ft. long has a resistance of 1 ohm. A piece of No. 10 B. & S. gage copper wire 1000 ft. long has a resistance of almost precisely 1 ohm.

The volt is the unit of e.m.f.; that is, it is the unit whereby the tendency to establish electric currents may be measured. By international agreement, 1 volt is that e.m.f. which will establish a current of 1 amp. through a resistance of 1 ohm.

Electric Current Is Like a Hydraulic Flow

The general analogy between hydraulic and electric circuits should be appreciated. An electric circuit (Fig. 1) comprises conducting wires which are composed of readily moved electrons. These wires are arranged in air or in some other insulating material which tends to prevent the egress of electrons from the wire. Hence when a voltage developed by a generator, or by some other means, is impressed across the ends of the wire the electrons are forced to move around in the wire and through the conducting members connected to it. By the utilization of properly designed devices these moving electrons may be made to do work—to transmit electrical energy. Note that the copper transmission wire resembles a hole through the air through which the electrons can be moved with relative ease. Air is an insulator, so electrons can be moved through it only with the greatest difficulty.

Similarly, the hydraulic circuit of Fig. 2 comprises a pipe line full of water. The pressure developed by the pump will cause the water in the circuit to move and thus turn the water motor. Just as the electric circuit is full of electrons or electricity, the hydraulic circuit is full of water. Electricity may be thought of as resembling a non-compressible, weightless fluid which permeates all space.



Ohm's law states the relation between current, resistance and e.m.f. It is merely a restatement, as applied to electric circuits, of the general law which governs all physical phenomena: The result produced is directly proportional to the effort and inversely proportional to the opposition. In an electric circuit the current established is the result. The e.m.f. which establishes it is the effort and the opposition is represented by the resistance. Thus it may be written for an electric circuit:

$$I = \frac{E}{R} \quad \text{(amperes)} \tag{1}$$

$$R = \frac{E}{I} \quad \text{(ohms)} \tag{2}$$

$$E = I \times R \quad \text{(volts)} \tag{3}$$

Here I = current in amperes which flows in the circuit or in the portion of the circuit under consideration; R = the resistance of the circuit or the portion of the circuit under consideration in ohms; E = the e.m.f. in volts across the circuit or the portion of the circuit under consideration.

FIGS. 3 AND 4. HYDRAULIC ANALOGY TO DIRECT-CURRENT (LEFT) AND TO ALTERNATING-CURRENT (RIGHT) GENERATOR AND CIRCUIT

Ohm's law may be applied to an entire circuit or to a portion of a circuit. When applied to an entire circuit the amperes in the entire circuit equals the volts across the entire circuit divided by the resistance of the entire circuit. When applied to a portion of the circuit the current in that portion of the circuit equals the voltage across that portion divided by the resistance of that portion.

Electric currents may be divided into two general classes: (1) direct currents and (2) alternating currents. A direct current is one which flows always in the same direction. A direct electric current is analogous to the hydraulic current which would be produced in a pipe circuit (Fig. 3) by a centrifugal pump which causes the fluid to flow always the same way. An alternating current is one the direction of which is reversed at regular intervals. An alternating electric current is analogous to an alternating fluid current which would be circulated in a hydraulic circuit (Fig. 4) by a reciprocating pulsator.

Further classifications of direct currents are: (1)

Continuous currents—which are steady, non-pulsating direct currents, (2) constant currents—which continue to flow for some time in the same direction and with unvarying intensity and (3) pulsating currents—which are regularly varying continuous currents.

The electrical resistance of a conductor is determined by various factors. Thus the resistance of any conductor will vary with: (a) The material of the conductor, (b) directly as the length of the conductor, (c) inversely as the area of the conductor and (d) the temperature of the conductor. That is, the properties of a conductor, which determine the opposition which it offers to the flow of an electric current (electrons)

TABLE I. PROPERTIES DETERMINING FLOW OF CURRENT IN HYDRAULIC AND ELECTRIC CIRCUITS

	Of Water Current Through a Pipe	Of Electric Current Through a Wire
1	Diameter of pipe	Diameter of wire
2	Length of pipe	Length of wire
3	Material of pipe or its internal smoothness	Material and temperature of wire

through it, are (see Table I) somewhat analogous to those which determine the flow of fluid currents in hydraulic circuits.

The circular mil (circ.mil) (Fig. 5) is the area of a circle $\frac{1}{1000}$ in. in diameter. The areas of electric conductors are usually measured in circ.mils. The

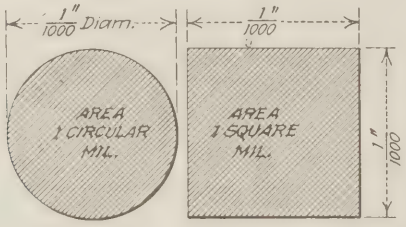


FIG. 5. SQUARE MIL AND CIRCULAR MIL

area of any circle can be expressed in circ.mils by squaring its diameter expressed in thousandths of an inch.

Thus, since $\frac{3}{8}$ in. = 0.375 in., the area of a circle $\frac{3}{8}$ in. in diameter would be 375 × 375 = 140,625 circ.mils. The area of a circle 0.005 in. in diameter would be 5 × 5 = 25 circ. mils.

The square mil (sq.mil) (Fig. 5) is the area of a square having sides $\frac{1}{1000}$ in. long. Areas of rectangular conductors are sometimes measured in square mils. Areas in square mils are obtained by multiplying

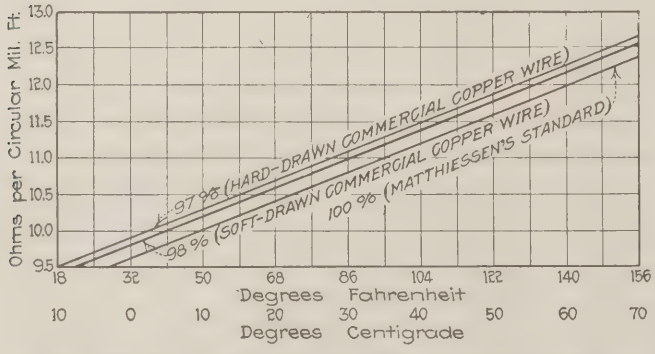

FIG. 6. GRAPHS SHOWING THE RESISTANCE PER CIRCULAR MIL-FOOT OF COPPER OF DIFFERENT CONDUCTIVITIES AT DIFFERENT TEMPERATURES

It is usual to specify that soft-drawn copper shall have 98 per cent. conductivity and hard-drawn copper 97 per cent. Hence, commercial copper wire has about these conductivities

together the length and breadth of the rectangle expressed in thousandths of an inch.

Thus, the area of a rectangle ½ in. wide and 2 in. long would be 500 × 2000 = 1,000,000 square mils.

To reduce square mils or square inches to circular mils or the reverse the following equations may be used: Square mils = circ.mils times 0.7854; circ.mils = square mils divided by 0.7854; circ.mils = square inches divided by 0.0000007854; sq.in. = circ.mils times 0.0000007854.

The circular mil-foot (circ.mil-ft.) is the unit conductor. A wire having a sectional area of 1 circ.mil and a length of 1 ft. is a circular mil-foot of conductor.

Resistivity is specific resistance which may be expressed in ohms per unit volume; for example, re-

TABLE II. APPROXIMATE RESISTIVITIES—SPECIFIC AND RELATIVE—OF CONDUCTORS*

Conductor	Resistivity = p (Resistance of 1 Circ. Mil-Ft. in Ohms) 0 Deg. C. or 32 Deg. F.	23.8 Deg. C. or 75 Deg. F.	Relative Conductivity (As Compared with Copper)	Relative Resistivity (As Compared with Copper)
Silver, pure annealed	8.831	9.674	108.60	0.925

Gray cast iron	684.000	.....	.....	.....

* International Textbook Co.'s "Electrical Engineer's Handbook." See Croft's "American Electricians' Handbook" for more complete table.

sistivity may be expressed in ohms per centimeter cube or ohms per inch cube. However, it is usually most convenient, in practical work, to express and deal with resistivities in ohms per circ.mil-ft. (Refer to Table II). For practical purposes the resistivity of commercial copper wire (Fig. 6) at ordinary temperatures may be taken as 11 ohms per circ.mil-ft.

Conservation of First-Aid Supplies

A great many of the mines keep a supply of first-aid material on each level of the mine, such as triangular bandages, compresses, roller bandages, adhesive tape, iodine, etc. These supplies are placed on the different levels for the sole purpose of rendering first-aid to the injured. They are usually kept under lock and key, but in many instances the locks are broken and the supplies are taken out and used for various purposes.

The triangular bandages are often used to wrap broken hose or for "sweat rags," the adhesive tape to wrap broken hammer handles or the bottom of carbide lamps. This is a gross injustice to the company, which spends thousands of dollars annually for first-aid material. We can leave the company out of it entirely and say it is a gross injustice to the man himself. He cannot tell when he is going to need some of those supplies for a personal injury, and the bandage which should be on his head or arm may be on his air hose.

A hose cut with a rock may be repaired on top and made as good as new, but an arm cut with a rock and not given proper first-aid treatment is often lost. Let us get together and conserve the first-aid supplies and use them for the purpose for which they were intended. They are hard to get now, because Uncle Sam needs them for the boys "over there."—*Anode.*

Increasing Coal Mine Efficiency—II

BY CHARLES E. STUART
United States Fuel Administration, Washington, D. C.

SYNOPSIS—*In a general way, cutting machines are quite similar in their power requirements to locomotives. The proper means and speeds for driving mine fans as well as properly maintained air courses sometimes result in enormous economies in power. Fluctuating loads on the mine generating station or substation should be avoided as far as possible. This is often much more nearly possible than many operators believe.*

III—An Analysis of Performance of Cutting Machines

THE general considerations which govern the utilization of a mine locomotive, in order that maximum efficiency may be obtained, apply in a similar manner to the cutting machine. There are, broadly speaking, the same elements of avoidable and unavoidable loss of time. There is also the need of so developing the mine that the cutting machine can be used at its rated capacity. Bad power conditions and inefficient handling are factors to the same degree, as in the case of the locomotive, and there is the same loss in productive effort.

The ideal method of working a cutting machine is to give one machine a section containing sufficient places to enable the machine runners to cut each place every other day, letting the loaders clean up in the same manner. If this be done, the machine runners usually stay on one entry and go into the rooms consecutively instead of running all over the mine to cut a place here and another there, thus consuming more time in tramming than in cutting.

In some of the large mines in Pennsylvania and Illinois these ideal cutting conditions are very nearly attained. In one case with which I am familiar, the depth of the undercut has been proportioned to the width of the room and the height of the coal, in order to give just enough coal for the loaders to clean up in one or two full days. This enables the maximum effort to be put forth by the loader and machine runner.

Table II shows a record taken through a period of 31 days, using the Sullivan shortwall continuous cutter. During this time 317 places were cut, or an average of 10.22 places per day. Column 12, headed "Time Lost Waiting for Places," shows that 73 hours 10 minutes were lost. The runner's report shows that probably 75 per cent. of this delay could have been avoided.

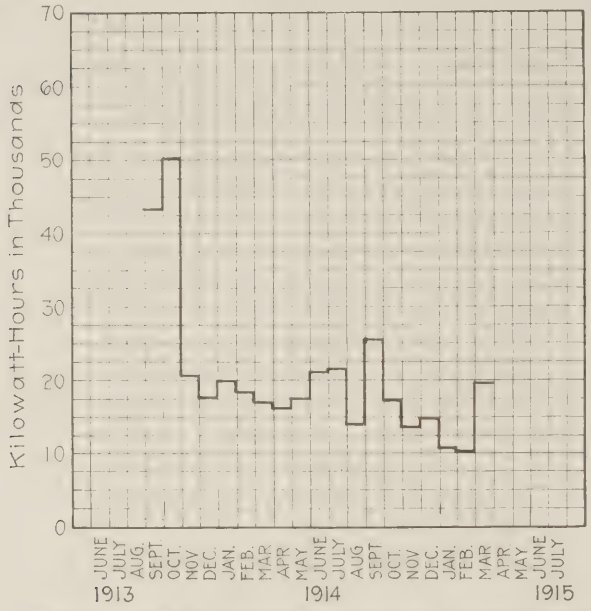

FIG. 7. POWER CONSUMPTION OF A MINE FAN

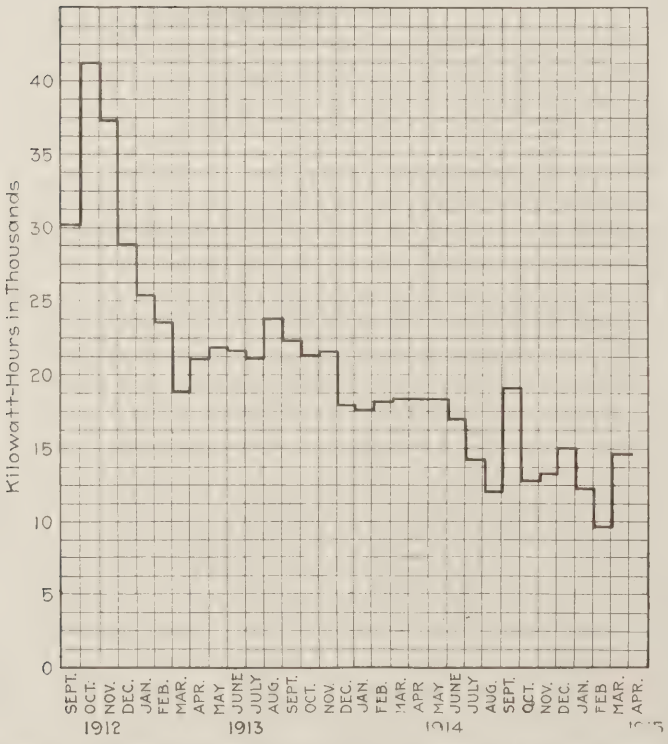

FIG. 8. POWER CONSUMPTION OF A MINE FAN, SHOWING RESULT OF VENTILATION IMPROVEMENTS

These delays were designated as arising from such causes as "blocked by motor," "no more places cleaned up," "off the track," etc. Since the average time consumed in cutting a place was a little less than 30 minutes, it is probable that 100 additional places could have been cut if these delays had not occurred, making a total of 417 places, or an average of about 13 places per day. The average noted in Table II is above the usual. There are cases where runners have cut from 17 to 22 places in 10 hours, these being, however, record runs.

Table III represents tests of power consumption of Sullivan room-and-pillar machines, with a 6-ft. 6-in. and 10-ft. 4-in. cutter-bars. It also gives the comparative economies of machines. There is no information contained in these tables which would not be of interest and value as determined at every property using a cutting machine. These tests and supplementary observations develop the following facts: The first cost of the machines is practically the same. Repairs on the longer bar machines are less than those on the shorter machines; they are heavier throughout and have fewer parts relatively. Experienced men can cut as many

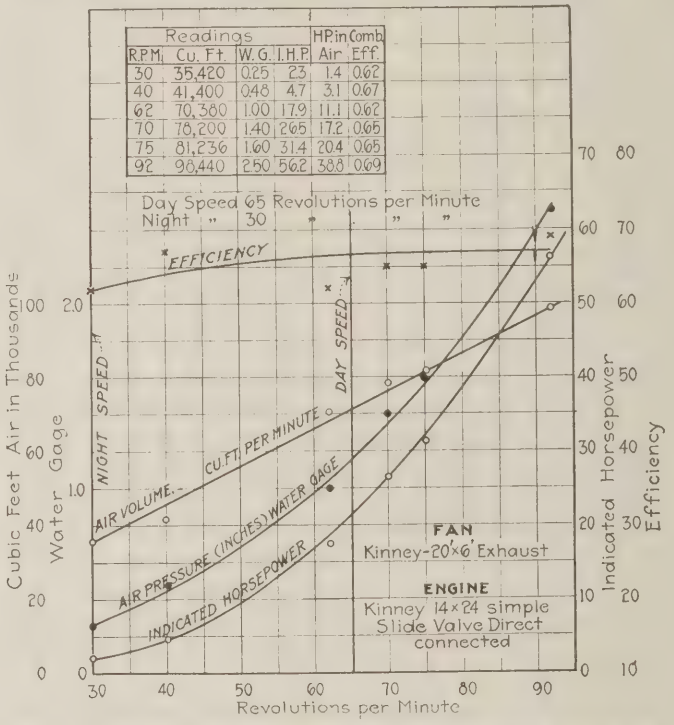

FIG. 9. POWER REQUIRED BY STEAM-DRIVEN MINE FAN

places with the long bar machines as with the short bar machines if voltage is maintained. Loaders after the long bar machines use less powder per ton of coal, as the same total amount of powder is used per place.

IV—Power Demand and Consumption of Mine Fans

Figs. 6, 7 and 8 show the results of alterations made with the object of reducing power consumption and power demand of mine fans. These alterations were preceded by investigations and tests which developed the following facts: (1) The fans were handling an amount of air in excess of the requirements of the mine; (2) large proportions of this air failed to reach the working faces, due to leakage, defective stoppings, brattices and similar reasons; (3) the air pressure, as shown by the water gage, was unduly high, owing to the air current being carried in too few splits.

These conditions were corrected by carrying to the faces the full amount of air required for good ventilation and by reducing the speed of the air current. Stoppings were repaired, and stone was substituted for timber in their construction. The speed of the air

COMPARATIVE ECONOMY IN COAL OF SAME THICKNESS:

Average width of place (wide and narrow), 16 ft.
Average depth of cut 6 ft. 6 in. bar, 5.61 ft. of 10 ft. 4 in. bar, 9.24 ft.
Number of square feet undercut per place with 6 ft. 6 in. bar, 89.8 sq.ft.; with 10 ft. 4 in. bar, 147.8 sq.ft.

Power per place @ 1½c. per kw. hr. with 6 ft. 6 in. bar, $\frac{22.8 \times 89.8 \times 1.5c.}{1000}$ = 3.1c.; with 10 ft. 4 in. bar = $\frac{25.1 \times 147.0 \times 1.5c.}{1000}$ = 5.6c.

Labor per place	100.0	
Total cost per place, labor and power	103.1	110.0
Total cost per square foot undercut' labor and power	1.15c.	115.6c.
Saving by 10 ft. 4 in. bars	31 per cent.	0.79c.
For rooms with two tracks, 36 ft. wide		
Number square feet undercut (same depths as above)	202.0 sq.ft.	332.6 sq.ft.
Power per place @ 1½c. per kw.-hr.	$\frac{22.8 \times 202 \times 1.5c.}{1000}$ = 6.9c.	$\frac{25.1 \times 332.6 \times 1.5c.}{1000}$ = 12.5c.
Labor per place	125.0	128.0
Total cost per place, labor and power	131.9c.	140.5c.
Total cost per sq.ft. undercut	0.65c.	0.42c.
Saving by 10 ft. 4 in. bars	35.4 per cent	

First cost of machines is practically the same; repairs on longer bar machine will be less than on shorter machine, as it is heavier throughout, and has fewer parts, relatively; experienced men can cut as many places with longer bars as with shorter ones, if voltage is maintained, and, in addition to above, loaders use less powder per car, as same total amount of powder is used per place.

current was reduced by: (a) Institution of added splits; (b) cleaning up falls of slate in the courses and tunnels; (c) by the use of additional air courses where possible.

The fans are now run at the speed required to obtain the quantity of air needed under corrected conditions. At night, on Sundays and holidays, half the amount of air is handled. In order to give the full amount of air for the remaining periods, two-speed motors were installed. In one case a change was made from steam to electric drive. Records show that while the steam drive was in use, the power consumption amounted to the equivalent of 4¼ kw.-hr. for every ton of coal mined. A constant-speed motor, when installed, cut the consumption of power for each ton of coal to 2½ kw.-hr., making a 70 per cent. saving by installing this one-speed motor. After about four months' service, a two-speed motor was installed and the fan was run at full speed during the operative period of the day, and at half speed at other times. The amount of power for each ton of coal then dropped to 6 kw.-hr., securing a 310 per cent. saving over the one-speed motor and a 600 per cent. saving over the steam drive.

I might emphasize that these data were compiled at a property which first used power manufactured at its own central station. Later it purchased power. The cost of these and other elaborate investigations, the results of which have made this property famous throughout the country for its efficient methods, represents a negligible fraction of the economies produced.

Figs. 9 and 10 show tests made on engine-driven mine fans in the Pocahontas coal fields. There is developed together with other information the horsepower required at different speeds and for different air volumes. These curves should be carefully considered in conjunction with Figs. 6, 7 and 8. The latter, as previously stated, show what may be done by proper investigation and adjustment.

V—Analysis of Power Demand and Consumption in Relationship to Capacity and Production

The demand on the generating plant of a coal mine or on the substation in cases where power is purchased is of a sharply fluctuating character. Fig. 11 shows the reading of a graphic meter taken at a 200-kw. substation. The extreme peaks are the result of short bad grades. The mine locomotive, when encountering these grades, momentarily

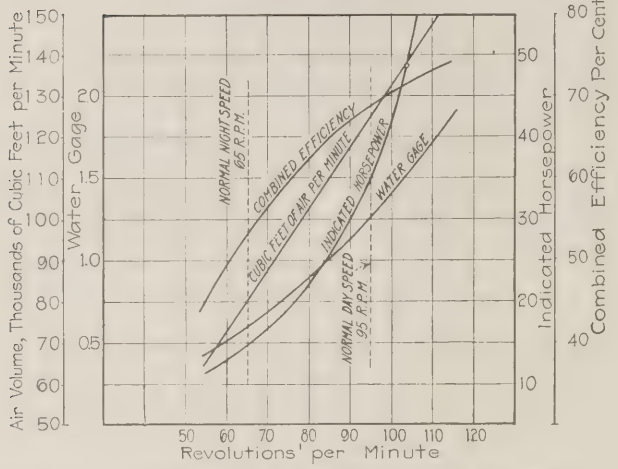

FIG. 10. CURVES OF A STEAM-DRIVEN MINE FAN

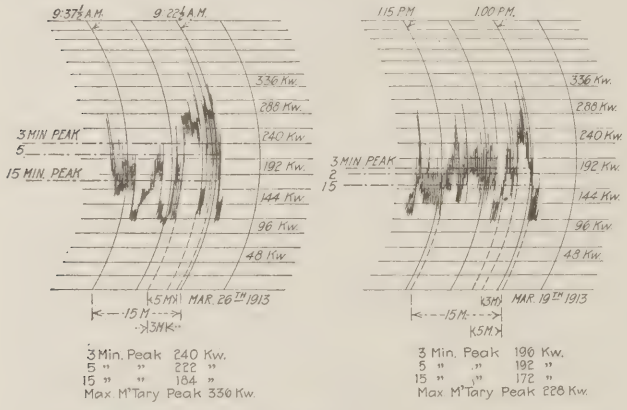

FIG. 11. DEMAND CURVES ON A 200-KW. PLANT

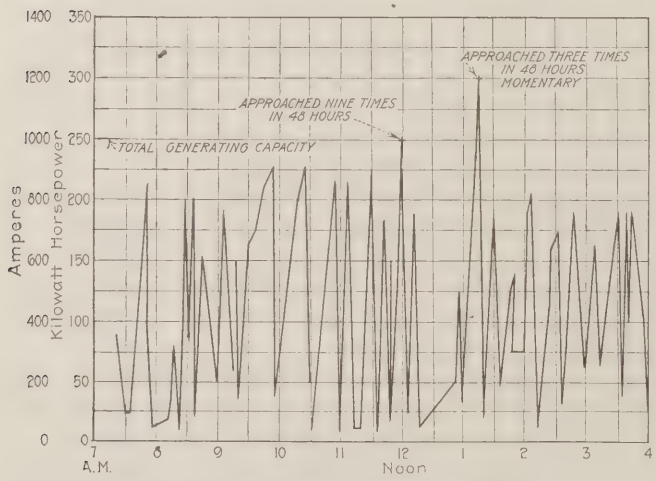

FIG. 12. ANALYSIS OF A MINE LOAD

loads up the station. Few mines are above criticism in this respect. With a large percentage of mines the load on the generating or converting station is largely composed of more or less avoidable demands.

Moreover, to an extent that is rarely appreciated, such conditions create a "bottle neck" to the entire haulage system. Thus a 10-ton mine locomotive on

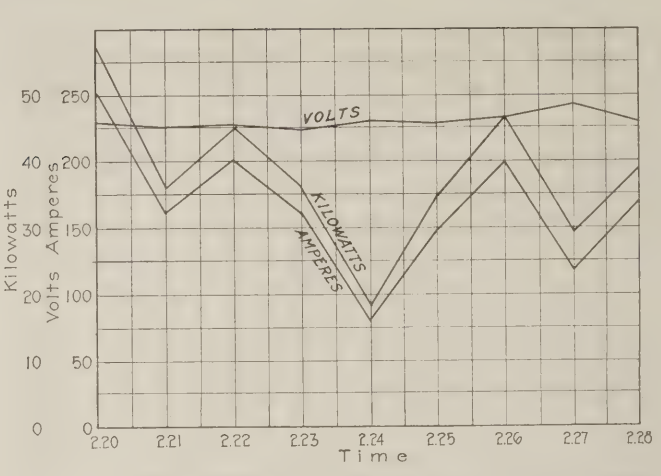

FIG. 13. POWER CONSUMED BY AN 80-HP. LOCOMOTIVE, PULLING 20 EMPTIES

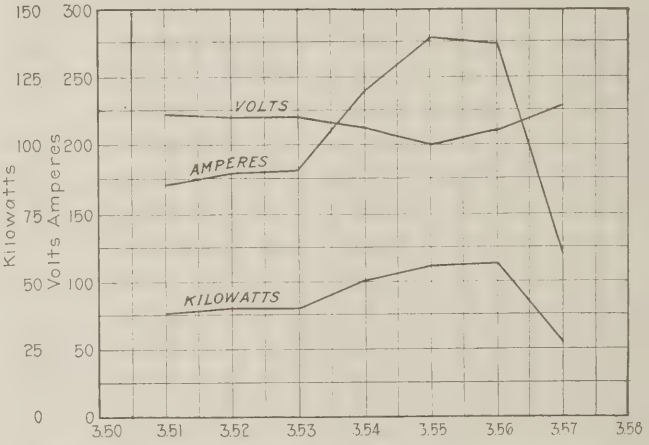

FIG. 14. POWER CONSUMED BY AN 80-HP. HOIST, PULLING 12 LOADED CARS

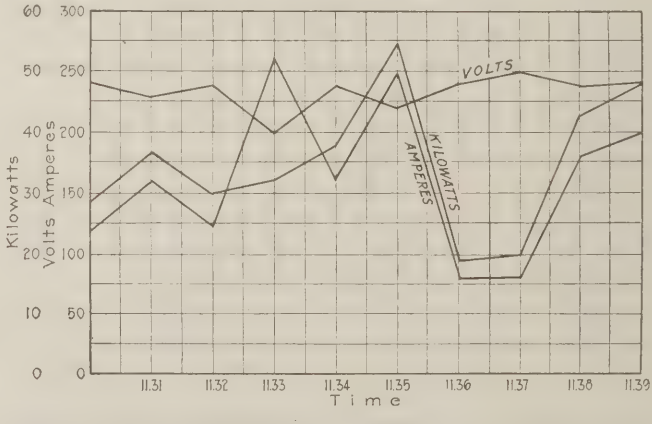

FIG. 15. POWER DEMAND OF TYPE B LOCOMOTIVE OF 80-HP., HAULING 6 LOADED CARS

level track should haul 31 loaded cars of 4 tons each. The same locomotive on a 6 per cent. grade will haul eight 4-ton cars, thus showing a decrease of 281 per cent.

It will be seen that the grades may be the determining factor in the number and weight of locomotives required, the capacity of the generating station or substation; also as to the weight of rails, the power demand and the power consumption.

Fig. 12 shows the analysis of a load as observed between the hours of 7 a.m. and 4 p.m. From the chart the plant seems to be as well loaded as is conservative. It was, however, desired to add to the load as shown a hoist demanding 150 kw. at full load, or

an additional 600 amp. In order to determine whether the generating plant could take care of such an additional demand, a test was run on those loads, which were the factors for consideration.

Figs. 13, 14, 15 and 16 show the demands of the locomotive and hoist on different dips. Adding the hoist load in this instance simply necessitated preventing the maximum demands of the locomotives occurring simultaneously. Where grades could not be reduced or avoided, there were two practical methods available to flatten the haulage demand; one, that of a simple signal-

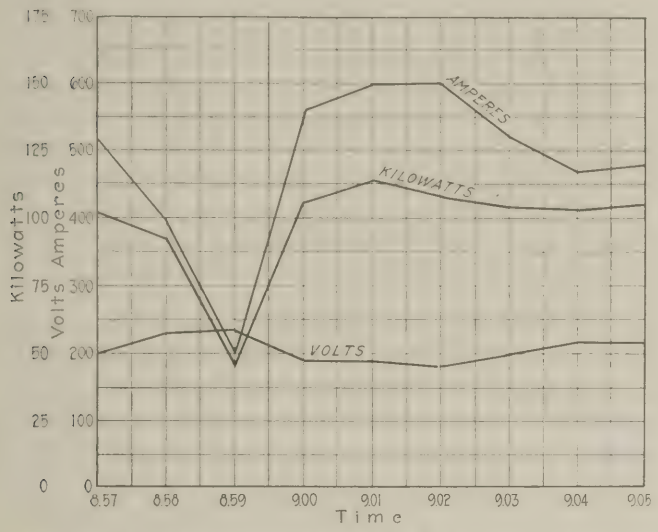

FIG. 16. POWER CONSUMED BY 2-F LOCOMOTIVES OF 200-HP., HAULING 14 CARS

ing device which would indicate trips on grade; the other roughly scheduling the main haulage locomotives.

The majority of mines on careful examination and test from an electrical and mechanical standpoint will develop the following facts: (1) By systematizing the load, a steam station or substation apparently overloaded with the breaker tripping many times a day, resulting in loss of speed and efficiency, can be operated in a normal manner. (2) Conversely, many stations apparently fully loaded can take on more cutting machines or locomotives without addition to either substation or steam station, as the case may be.

Table IV, showing a monthly analysis of power consumption, was made with the instruments belonging to the mine investigated. The cost of the instruments necessary to such an analysis is negligible compared with the savings which have resulted from their use.

It is characteristic of the mine as of the factory that

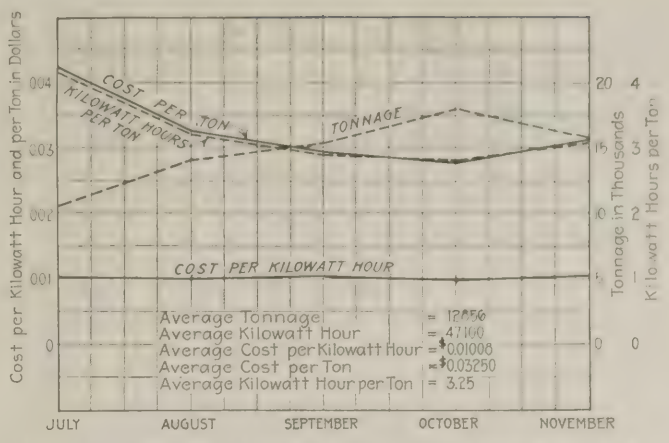

FIG. 17. OUTPUT, CONSUMPTION, COST PER TON AND PER KILOWATT-HOUR OVER 5 MONTHS

there is more or less idle machine operation. This is particularly true where a mine is equipped with more than one converting or generating set. It is, moreover, generally appreciated that machinery is operating at its highest efficiency when approximately fully loaded. While the characteristics of power demand in a mine make full load operation of most of the equipment out of the question, at the same time through analyses such as the foregoing, and through systematizing, the power consumption and demand of many mines have shown marked reduction. This in turn has been reflected to a valuable extent on the cost sheet.

There is a psychological aspect to this as in many other cases of economies produced and demonstrated.

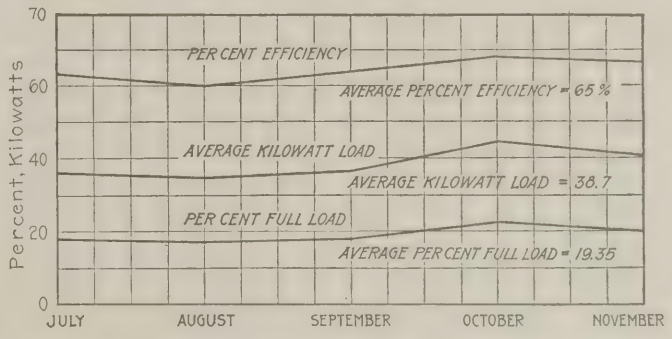

FIG. 18. RATIO OF AVERAGE CONSUMPTION TO FULL LOAD CAPACITY

An organization trained to give thought to such points will invariably give thought to other possibilities for reducing costs and for increasing the efficiency of operation.

Figs. 17, 18 and 19 develop graphically important facts

concerning the power requirements of a mine. Fig. 17 gives the tonnage output monthly of the mine investigated through a period of five months. There is shown also the monthly kilowatt-hour consumption, the monthly cost per kilowatt-hour, the monthly cost per ton and the kilowatt-hour consumption per ton. The increased or decreased cost of power corresponding to variation of production is also indicated.

Fig. 18 shows the ratio of the average power consumption to the full load capacity of the substation. It shows also the average hourly kilowatt output of the station. In addition, the efficiency of the station is indicated. This information is provided to correspond to the monthly statement shown in Fig. 17.

It will be observed that the average percentage of load—that is, the load factor of this station, which is

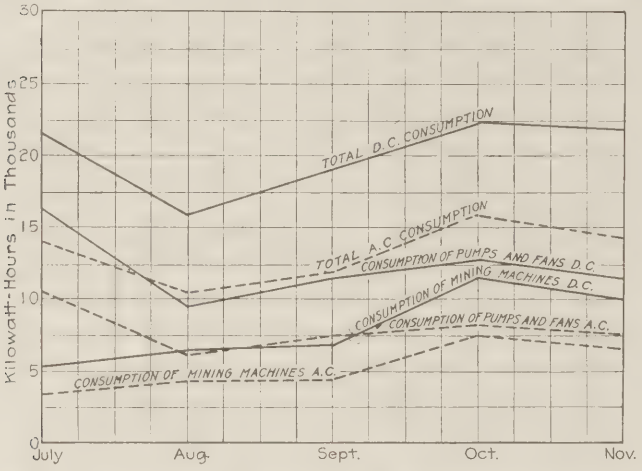

FIG. 19. THE IDEAL CONDITIONS OBTAINABLE THROUGH USE OF ALTERNATING CURRENT

a 200-kw. station—is 19.35 per cent. and that this average corresponds to the average tonnage of 12,856 tons per month.

Fig. 19 shows the ideal condition that can be obtained by using alternating current as far as possible. This figure shows the monthly consumption in kilowatt-hours of inside fans, pumps and mining machines, both on a basis of using alternating-current motors and direct-current motors. It is shown that the saving by using alternating-current motors would average 7233 kw.-hr. per month.

The foregoing is an excellent illustration of where the question is one of applying purchased power, or power from a mine power station generating alternating current. A large proportion of mines when equipping with purchased power continue all of their motor-driven apparatus on a direct-current basis. It can be readily shown, or in fact deduced from the figures used, that where alternating current is available a change-over would result in a decreased cost as incident to decreased power consumption, as well as demand, which would fully justify the change. But most important is the desirability of not loading up the substation with a load that can be more cheaply and reliably carried by stationary transformers.

(To be continued)

Based on the mortality statistics of the allied armies, a soldier's chances are twenty-nine chances of coming home to one chance of being killed.

Coke Making in New South Wales*

An excellent silvery coke from the bituminous coal of the Newcastle (N. S. W.) district has been made for upward of fifty years in beehive coke ovens. One beehive plant was erected in the Southern Coalfield in 1891, at which, by crushing the small coal, a superior hard coke was produced. The large smelting plants at Broken Hill and others formerly imported the whole of their coke supplies from Germany, the north of England, or from South Wales. When the huge deposits of lean copper ores at Mount Lyell (Tasmania) and elsewhere were being developed, proposals to use Australian coke led to the making of practical experiments. These showed that the steam coal of Illawarra, although higher in ash and in fixed carbon than bituminous coal from Newcastle, produced a harder coke, cellular in structure and better adapted to withstand the pressures in large furnaces, while its ash content was not materially higher than in coke from Newcastle. To make one ton of Newcastle coke fully two tons of coal are used, while from 26 to 27 cwt. of southern coal only are required.

Mount Lyell began the erection of ovens at Port Kembla, and soon after the Broken Hill Proprietary erected a larger plant at South Bulli. South Clifton Colliery erected a plant of beehive ovens, and other smelting and private companies have erected large batteries of ovens near the other collieries. The saving in the cost of coke to the Broken Hill company must have been considerable.

It was early found that rectangular ovens handling large quantities of coal, saved time and expense in charging, enabled the coke to be pushed out by electrical or hydraulic pushers or rams, and gave better results than beehive ovens. Careful consideration was given to the adoption of byproduct ovens, but the proposal was abandoned as impractical with southern coal on account of the low yield of tar and ammonium sulphate in the lean coals, the great cost of importing (in part due to the excessive tariff) and erecting byproduct apparatus from Europe, and the additional cost of sending the products to Europe.

A modification of the Welsh or Thomas oven gained favor. The first battery was erected with side and bottom flues measuring 21 x 4 x 5½ ft. Smelting companies erected ovens measuring 30 x 2 ft. 9 in. by 6 ft., with horizontal side and bottom flues. Other firms adopted larger ovens 30 x 6 ft. 8 in. by 6½ ft., and 30 x 8 x 5½ ft., some with vertical flues and some without. All the batteries use slack coal, crushed fine. Eight companies have up to the present erected 602 ovens.

With the exception of the beehive plants all the others use hydraulic, electric or steam pushers and levelers. One employs a Buchanan compressor and charging-box in which the pulverized material is pushed into the oven. This machine also quenches the coke by sprayers. In the majority of the plants a portion of the waste gases is employed to raise steam for use in the coke plant or for the generating plants at the mines.

The numerous difficult conditions imposed by wage boards have considerably increased the already high

---

*From a paper by Dr. R. J. N. Robertson, presented at the Nottingham meeting of the Institution of Mining Engineers, Sept. 13, on "Recent Developments in the Coalfields South of Sydney."

cost of labor at the ovens. The excessive overtime imposed for work done between noon on Saturday and Monday morning has necessitated alterations of the usual practice of working ovens continuously, and charges are now adjusted so as to avoid Saturday afternoon or Sunday drawing. It has been found most suitable to burn for 72 hours. The higher temperature required for 24-hour burning necessitates the use of a higher quality of firebrick than has yet been made in Australia, the cost of which from Europe would be prohibitive.

The output of the wider coke ovens is nearly double that of the narrower ones, which, owing to labor restrictions, cannot utilize the advantages inherent in the arrangement of flues that they possess. The coke can be quenched in the wider ovens, and this avoids the dust and heat that largely contribute to the increased cost of labor and other hampering conditions. With the exception of one battery, the various ovens are charged through three or four openings from large larries. The doors are raised and lowered by hydraulic power.

In the year 1892 Newcastle produced 12,262 tons and the Southern district 5595 tons of coke; in 1914 Newcastle produced 28,264 and the Southern district 276,536 tons, which in 1915 was increased to 333,619 tons. A comparative analysis of the cokes produced are given in the following table:

An Investigation of Concrete Houses

An idea of how some concrete houses are regarded by the occupants is given by Milton Dana Morrill, architect, New York City, in his report of his own personal investigation. The investigation was made prior to a housing enterprise on which Mr. Morrill is now engaged. The group to which Mr. Morrill refers in the portion of his report here quoted was erected under his own direction. [The work has been described in *Coal Age* May 31, 1913, under the title of "Concrete Houses at Lackawanna Mine."—Editor.]

On Nov. 30-Dec. 1, 1917, I inspected a group of 40 reinforced-concrete dwellings at Nanticoke, Penn. These have been occupied for the last four years. The houses contain seven rooms, with outside toilet, no electric or gas lighting. The houses are piped for cold water only. The monthly rental is now $10. The older residents of the group still get their houses for $8, which was the established rental of four years ago. These houses have solid concrete walls, concrete floors, partitions, stairs and flat concrete roofs. The only woodwork is for windows and doors and their frames. The entire structures are of cinder concrete. Steel forms were used throughout the building operation; the marks of these forms show plainly inside and outside the houses, as no plaster or other finish has been applied, the concrete being painted only—except on six of the 40 dwellings, where the interior was finished with a skim white coat of plaster. These form marks give to the work a rough and unfinished appearance, both inside and out. From a structural standpoint, the houses seem to be standing well, with no repairs except a coat of paint since they were completed. The permanency of this construction for industrial houses is here clearly demonstrated, although the finish here given is too crude for the better class of industrial dwelling.

The renter is not particularly interested in the permanency of the house construction; neither does he give any particular value to the fireproof or sanitary quality of his house.

In order to get the tenants' viewpoint after living in these houses for several years, a list of questions was compiled and put to 15 different families in the group.

The questions asked were as follows:

1. How long have you lived in this house?
2. Have you ever seen any dampness in the house?
3. Do you find your house comfortable—warm in winter, cool in summer?
4. How many stoves do you have?
5. How much coal do you burn per month?
6. Do you like the casement or swinging windows?
7. Do you like the combination bathtub and washtubs installed in the kitchen?
8. What covering do you use on the concrete floors?
9. Do you find the floors cold or hard to the feet?

Many Facts Brought Out By Questions

These questions, together with observation, brought out the following facts:

Each seven-room dwelling was heated by the kitchen range and one large stove in the living room, requiring on an average of one ton of coal per month. All the families found the combination washtubs and bathtub a convenient and a useful fixture. Practically all the families would prefer the usual sliding windows instead of those with casement or swinging sash. In all the houses inspected the concrete floors were covered with rugs, in the living rooms, and with linoleum in the kitchens. In some of the answers given there was some variation, so it may be helpful to give these answers in detail. For indentification the facts brought out by the tenants have been put down under the house number where each inquiry was made.

Dwelling No. 303—Four years' occupancy. No dampness, but walls sweat on wash day. House very cool in summer.

No. 309—Four years' occupancy. No dampness. Concrete floors found hard on the feet.

No. 325—Three years' occupancy. Walls sweat on wash day. Rather have wood floors to live on.

No. 315—Had just been vacated and was being washed out before arrival of new tenant. The floors were being flushed with soap and water and scrubbed with a broom. A dwelling of this construction can be cleaned very thoroughly. There are no concealed spaces in the construction to harbor vermin or insects.

No. 326—No dampness found. House found warm in winter, cool in summer.

No. 936—Four years' occupancy. No dampness found. Concrete floors not found cold, but would prefer wood covering.

No. 939—Four years' occupancy. Would prefer wood floors.

No. 921—Four years' occupancy. No dampness found. Even temperature, cool in summer and warm in winter.

No. 923—No dampness observed. Construction preferred having wood floors. Cement floors not found cold, but wood floors preferred—"easier to fasten carpets down."

No. 924—No dampness found, but concrete floor found hard.

No. 934—Walls sweat on wash day. Finds house warm in winter, very cool in summer. States that did not like concrete floors at first, now finds them O. K.

No. 327—One year occupancy. No dampness found. Casement windows preferred. More air in summer. Wood floors preferred.

No. 333—Occupancy one year and three months. Cellar found damp. Finds house cool in summer, about like wood house in winter.

In the six dwellings where the walls were finished with a skim coat of white plaster directly over the concrete

walls, this has given considerable trouble. Steam from washing has loosened this thin plaster coat, and much of it has had to be replaced.

This investigation of these concrete houses would seem to show that cinder or slag concrete, when properly made and reinforced, is a satisfactory construction for the walls of dwellings. It would further show that it is necessary to furr such concrete walls if sweating is to be eliminated. The investigation further shows that to get an attractive and permanent exterior finish these concrete walls should have a stucco finish.

While the concrete floor has many advantages from a permanent fireproof and sanitary point of view, this investigation shows clearly that the tenants much prefer a dwelling with the usual wooden floors.

The permanency of this construction is at once apparent. These houses will require an occasional coat of paint and the doors and windows might after many years have to be replaced, but otherwise there seems to be no reason why these houses should not be as good in 50 or even 100 years as they are to-day.

These houses were designed and built to accommodate the families of the average mine laborer, whereas from the inquiry made they are occupied to a large extent by the families of the mine foremen. These men receive higher wages and could afford to rent and would gladly occupy better finished houses, with modern conveniences, such as electric lights, bathroom and furnace heat, if such houses were available close to their work—*Concrete,* September, 1918.

Novel Brick and Concrete Work

Some interesting underground construction is being carried on at one of the large mines of the Northwestern Mining and Exchange Co., in Clearfield County, Pennsylvania. The shaft station at the foot of the hoisting shaft is built entirely of brick to a point at which the company thought the roof would support itself. It was found that it would not, and Fig. 1 shows the new steel cap-pieces in place supported by wooden timbers which will shortly be removed and replaced by

FIG. I. STEEL CAP-PIECES SUPPORTED BY WOODEN TIMBERS

a concrete sidewall. The illustration also shows the brick arch work at the shaft station.

Fig. 2 shows an important junction point in the mine. The tracks in the foreground go to the shaft bottom. The entry from which the cars are coming

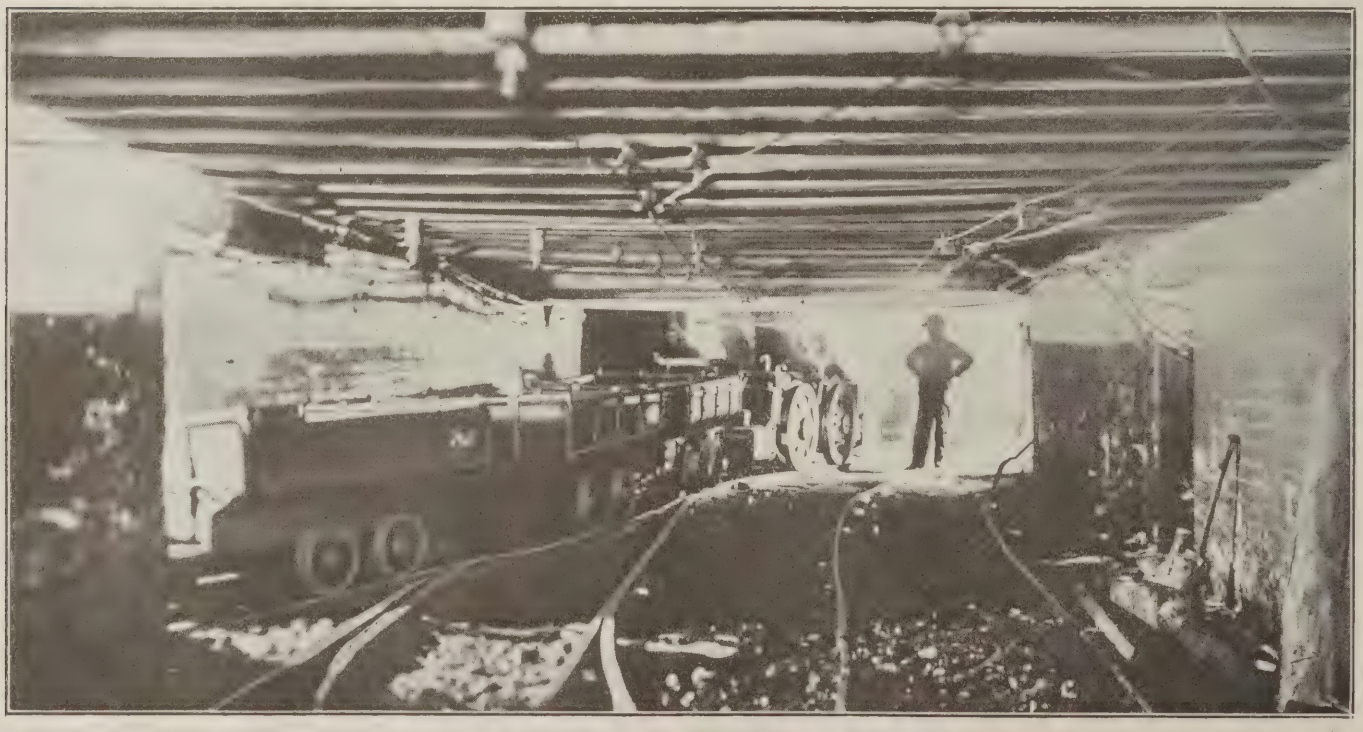

FIG. 2. IMPORTANT JUNCTION POINT IN THE MINE; NOTE BRICK WALLS AND ROOF OF STEEL I-BEAMS

FIG. 3. SHOWING HOW BRICK PIERS COMPARE WITH OLD WOOD TIMBERS

is the empty track, the two entries in the background going to different parts of the mine. It will be noticed that the walls are of brick and the roof of steel I-beams. This type of construction is used at all important junction points in the mine where the roof will not support itself.

In Fig. 3 a new "stunt" in the use of brick piers is shown. These piers are 8 x 30 in. and are set up on as straight a line as possible. Across the top of these piers a 60-lb. steel rail is laid, giving a bearing for the I-beams that would not ordinarily come on top of the piers. To the left of the illustration the old wood timbers can be seen standing, but these will shortly be replaced by brick piers.

The trolley wires are supported from the I-beams. Two pieces of steel are bolted to the beam, these projecting downward, a block of wood being fastened between them. To this block of wood the hanger for the trolley wire is fastened.

Coal Production for First Half of 1918

Bituminous coal production during the first half of 1918 was 311,216,000 tons. This is an increase of 12 per cent. over the previous high record made during the same period of 1917. Anthracite production from Apr. 1 to Sept. 28 was 51,651,000 tons. This shows an increase of 2.1 per cent. over last year's record. The figures are those of C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey. They were made public by the Fuel Adminstration with the following comment:

These production records were established in the face of many handicaps, chief of which was a reduced man power at the mines. It is estimated that the draft took between 50,000 and 60,000 coal miners during the last year, while probably as many men left the mines to work in other war industries.

By working more regularly than ever before the men who remained at the mines have been able to offset this loss in man power. Responding to appeals to their patriotism, which have been made directly to them by representatives of the Fuel Administration, the miners generally have been working full days and full weeks and foregoing many of the holidays and vacations which they were accustomed to take in the past.

Car shortage has limited production during the last six months. The weekly reports show that from 4 to 18 per cent. of full time has been lost by lack of cars for loading. In most districts, however, there has been a material improvement in this respect during the last few months. The loss of time during the last week of September was 6 per cent.

A factor that may tend to curtail production during the current month is the appearance of Spanish influenza in many of the mining districts of the east. Every effort is being made by the mine authorities to prevent the spread of the epidemic, but temporarily, at least, the precautionary measures that have had to be taken, as well as the disease itself, will have an adverse effect on the production returns from certain districts.

Although the bituminous tonnage of the last six months broke all previous records, it was still 10,897,000, or 3.4 per cent. short of the requirements for that period. Because of the great increase in the demand for coal for the nation's war industries and other military purposes, the requirements for the last six months exceeded those of the same period in 1917 by 44,315,000 net tons, or approximately 16 per cent.

The deficit in bituminous production must be made up in the second half of the production year by a still further increase in production, by conservation, which will reduce actual consumption below the estimated requirements, or by a combination of both.

Terms Used in Timbering

Certain terms are used in connection with timbering work in Illinois mines. Thus a "collar bar" is a timber used to hold up top and is placed parallel to the entry and across the room neck; this is the only place in the mine where such a timber is found. A "cross bar" is a term used to denote a timber which is placed at right angles to an entry. It may be found at any point on an entry.

Purchase of Mining Machinery and Supplies

By C. E. BOWRON
Birmingham, Ala.

SYNOPSIS—*Mining machinery is of two general classes—that built for long service and that built to operate for a short time only. Several considerations must be taken into careful account when buying equipment. Per pound prices by themselves are hardly comparable unless the machines in size, weight, capacity and design are nearly identical or at least closely similar.*

THE judicious purchase of mining machinery and supplies demands careful consideration of many factors. All mining men are familiar with machinery and apparatus at various plants which is "too good to throw away," but "not good enough to keep." Too much machinery has been bought and is still being purchased on a price rather than on a cost basis. Thus the cost of a piece of machinery does not end with the payment of the original invoice, and to get at its true lifetime cost we must add the expense of keeping it in an efficient state of repair and also the cost of operating it.

A first consideration that must be given attention is the duty required from a machine, its probable cycle of operation and its probable life. We can afford to pay more for a piece of machinery intended to yield many years of service than for one expected to give only a few months' service; more for a piece which must operate 24 hours a day than for one to operate 1 hour daily; or when, by paying more, we insure against breakdowns and gain in economy of operation.

Expensive Versus Cheap Machinery

In a great many lines of machinery at least two grades exist. It will be found upon careful investigation that there are usually good reasons for the more expensive grades, perhaps not always apparent to casual inspection. Among these are heavier or more economical design, higher grade metals, more expensive finish, higher grade workmanship, interchangeable parts built to templet, extra attachments, etc. In some lines the cheaper designs are termed "competitive" and are those offered when the simplest, plainest and cheapest thing that will do the work for a while is wanted. One is rarely surprised at their breakdown and early failure. For example, in looking over some old proposal sheets I find two boiler feed pumps offered for the same duty, one a 10 x 7 x 12 duplex piston pump, plain fitted, weighing 1740 lb., price $290, and the other an 8 x 5 x 12 duplex, outside-packed plunger pump, bronze fitted, weighing 3500 lb., price $1050.

After a survey of the requirements, it is therefore the part of wisdom, in asking for proposals, to advise some of the leading specifications or to state fully the required duty to be performed, with some statement as to the grade or economy of the machine desired. Proposals may thus be all made on the same grade of machinery and therefore be truly competitive. Furthermore, they may then be compared relative to the fine points of difference. It is wise to purchase machinery a little too large rather than just up to the capacity desired, or a little too small, as mining plants often have a disconcerting way of "growing too big for their breeches."

The specifications sent out and the proposals received, for machinery of any size or importance, should be the subject of conference between responsible officials such as the master mechanic, engineer, superintendent or others. There are entirely too many men entrusted with the specification and purchase of machinery whose experience is limited, who are not familiar with the values involved, or who are hidebound or perhaps prejudiced in favor of a certain make because they are familiar with it only. Experience in buying will, in the course of time, enable one to confine inquiries to those firms whose goods have been found satisfactory and yet secure sufficiently diversified bids from which to choose.

New Machinery Should Be Investigated

Machinery of new design, even when brought out by reputable concerns, must be bought with caution and with strong guarantees. Some years ago I purchased an air compressor of new design (now a familiar one) from one of the leading manufacturers. It so happened that this firm had built numbers of this type of machine in smaller sizes, but the machine bought was the first one of its size. While on the whole its performance was satisfactory, the makers made perhaps two dozen changes in small details when my employers purchased a second machine a year later, most of the changes resulting from our experience with the first machine.

Proposals should include full specifications on machinery or apparatus offered, advising sizes and dimensions of leading parts, description of metals to be used, weights, power required to operate (in the case of power-consuming machinery) and other essential data, accompanied by blueprints and photographs where necessary to give a clear idea of appearance or construction. It is sometimes like pulling teeth to secure essential data for comparison, from some firms who perhaps fear to disclose the secrets (?) of their designs.

Having in hand a number of proposals, these should be listed on large ruled sheets, showing names of bidders, with the various data in columns, so that the eye can follow each item all the way through the various bids. Prices should be reduced to the same basis—that is, all either f.o.b. factory or delivered at destination. Proposals should be carefully examined to see that all proper or desired items are included. Thus with engines, one maker may include a continuous oiling system worth possibly several hundred dollars, while another may include plain oil cups; one may include throttle valve, foundation bolts and washers, and another may not. Do not take it for granted that anything will be furnished unless it is included in the spec-

ifications or shown on the plan, forming a part of the specifications or proposal.

The price per pound may be worked out and compared. These per pound prices must be viewed with caution, however, and not be taken by themselves. With machinery of absolutely the same class and design, and approximately the same weight, they are a fair general criterion and in any case are a rough guide. It is a possibility, however, that the builder of a steam engine or air compressor, for example, may put an excessive and unnecessary amount of metal in a bedplate or other casting, which might make his product cheap per pound. If this extra weight were evenly distributed throughout the machine, this might be highly advantageous. It is necessary, therefore, in connection with a consideration of relative weights, to examine carefully the relative sizes of similar parts such as shafts, flywheels, rods, pins, bearings, the thicknesses of cylinder walls, etc., to see if the extra weight is justified. There are cases where builders still adhere to original patterns, too heavy in some details but satisfactory in service, rather than go to the expense of a new set of patterns; others, were they to redesign their machines, would make them somewhat heavier. Thus the criterion of weight alone will not by itself answer, but must nevertheless be carefully considered.

Relative Speeds of Machinery Important

In the case of machinery such as pumps, motors, engines, compressors, etc., the relative speeds of the machines offered should be taken into consideration. Slow-speed electrical machinery, especially, is necessarily more costly to build than that designed for high speed, since it involves the use of more copper. Slow-speed machinery in general would be expected to last longer and require less repairs than high-speed, as witness some of the old corliss engines still doing duty with very fair efficiency. In the case of air compressors, it would seem fair to compare their capacities and unit values at the same piston speed rather than on their nominal displacements at varying speeds.

The economy factor, in the case of power-consuming apparatus, should receive careful attention. Thus in the case of a large mine pump operating 12 to 24 hours per day, we could afford to pay a good deal more for a machine with an efficiency of 80 per cent. than for one with 60 per cent. efficiency. Let us assume a concrete example, say an electrically driven mine pump to handle 450 gal. per minute against a head of 500 ft., including pipe friction. There is thus $450 \times 8\frac{1}{3} \times 500 \div 33{,}000 = 56.8$ hp. in the water.

We are offered a triplex pump with an efficiency of 80 per cent., costing with motor $5500; and a centrifugal pump with an efficiency of 60 per cent., costing with motor $3500. Which shall we buy for a permanent installation, assuming that we can afford the more expensive machine? At 85 per cent. motor efficiency in both cases the horsepower inputs to the motors would be $56.8 \div 0.80 \div 0.85 =$ say 84 hp. in the case of the triplex and $56.8 \div 0.60 \div 0.85 =$ say 111 hp. in the case of the centrifugal. If power costs 1c. per kw.-hr. or $\frac{3}{4}$c. per hp.-hr., and the pump is to work 12 hours every day, the triplex would save in cost of power per year $(111 - 84) \times 12 \times 365 \times \frac{3}{4}$c. = say $887.

If from this we deduct 12 per cent. interest and depreciation on the $2000 difference in price between the two pumps, we would have $647 per year net saving, or, if we consider that the triplex would cost more for upkeep, say only $500 per year. If money is worth 6 per cent., we would be justified in spending $500 \div 0.06 =$ say $8000 for the triplex rather than accept the other pump for nothing, under the conditions assumed.

When a Cheaper Pump Is Advisable

If on the other hand the pump, to assume an extreme example, had to work only one hour per day instead of 12 hours, the saving in power would only amount to $\frac{1}{12}$ of the above figure, or $74, which would not equal the interest and depreciation on the extra investment required, and the purchase of the cheaper pump would be advisable. It might well be noted, although not germane to this article, that the common method of operating direct-acting steam pattern pumps underground with compressed air is one of the most wasteful power operations encountered at a coal mine.

In some lines of equipment it will be found that makers have closely agreed on base prices, leaving a decision as to purchase entirely to the relative merits of the goods. In other lines not only will prices be close together, but also general design and dimensions, and at times a decision gets down to a matter of personal preference based upon the general reputation of the maker or to personal familiarity with the several lines offered.

There will be found, for example, a marked similarity in design, dimensions and weights of several makes of large gyratory crushers as built by three or four manufacturers. There are sometimes proposals which are difficult to compare where designs, dimensions and all other details are widely different and where the question of suitability for the intended purpose is involved, making the purchase largely an engineering study: The various types of stokers and boilers furnish a good example of a case of this kind.

Should Exercise Care in Buying All Supplies

The same discrimination shown in the purchase of machinery, as has been roughly dwelt upon above, may well be exercised in the purchase of all kinds of apparatus and current supplies. To this end it is essential that proper records be kept showing the life and service obtained, together with first costs and unit costs. Under this head may be included such items as wire ropes, mine-car wheels and axles, belting, hose, packings, etc. Some simple form of card index will cover the needs of the average plant and the keeping of these records need not become burdensome. I recall one plant where records showed a saving in the monthly oil bill by the substitution of oil costing 50c. per gallon for oil costing 30c.

The same difference in grades, previously mentioned in machinery, will be found in many lines of supplies. Thus in rubber belting there exists a "standard" or competitive grade, with a better and perhaps a "best" grade and also a cheaper grade. In buying a pair of shoes or a suit of clothes you expect to get about the grade of stuff you pay for. In like manner the same applies when you are purchasing mining material; and you will not get something for nothing.

The larger mining companies with their well organized engineering, accounting and purchasing departments are of course buying along the general lines set forth above, but it seems that it is quite as important for the smaller company or operator to see that money is spent to the best advantage, with all factors thoroughly considered. It is hoped that such individuals and firms may find a useful idea or two in what has been written.

Where Government Runs the Coal Mines

Frank A. Henry, the United States Consul at Puerto Cabello, sends the following report on the coal mines in Venezuela:

"The only coal mines in the Puerto Cabello consular district that are being actively worked are located near Coro, in the State of Falcon. During 1917 these mines produced 4716 tons (of 2204.6 lb.) of the 20,164 tons produced for the whole country. The principal coal mines in Venezuela are situated near Guanta, and recent press reports indicate that production there has recently been increased to 70 tons per day. As imports of coal in 1916 amounted to 20,600 tons, of which 9100 tons were brought to this port, it is evident that local production will have to be very considerably increased before dependence on imported supplies will cease.

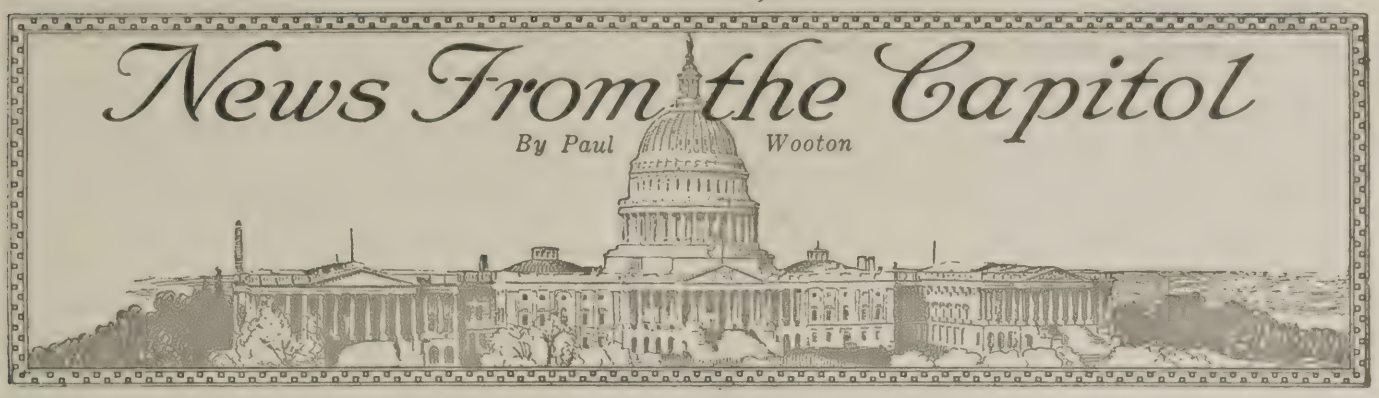
"The Coro mines are owned by the Venezuelan Government and operated through an administrator, who

also holds the same position for the Government-owned railway from Coro to its port, La Vela de Coro, about 9 miles distant. In his report for 1917 to the Minister of Fomento, the administrator called attention to the following conditions affecting the operation of mines. The methods of working are primitive in the extreme. Pick and shovel are the only implements used in mining. Lack of a suitable pump often results in the flooding of the mine and consequent suspension of work.

"Transportation conditions are equally primitive, and the necessity of hauling the coal several miles in small carts adds greatly to its cost. The extension of the La Vela-Coro R.R. a few miles to the mines would be the best solution of the transportation problem, but short of this the administrator has recommended the purchase of three motor trucks for this purpose. There are no storage places for the coal either in La Vela or Coro, nor is there any machinery for handling it at the water front. Only sailing lighters are used for loading vessels, and the charges, $0.77 per ton, add considerably to the cost of the fuel on board ship.

"The quality of the coal mined is said to be improving as the exploitation of the mine advances, and there is a good demand for all that can be produced. It is sold to the Government departments at $4.63 per ton and to private individuals at $7.72. During 1917, 4716 tons were extracted, the minimum production having been 126 tons in July and the maximum 645 in September.

During the year the cost of operations amounted to $25,760 and the receipts to $45,414. At the beginning of 1917 there was a stock of 4358 tons on hand, which was reduced to 60 tons at the end of the year. The sales during the last three years have been as follows: 1915, 2604 tons; 1916, 3637 tons; and 1917, 9014 tons.



"Due to the great demand for coal in Venezuela at present, owing to the cost and difficulties in importing from Great Britain and the United States, there is every reason to expect an increased output during the current year, although the same general methods of exploitation as formerly are likely to be followed."

Legal Department

DUTY TO INSPECT MACHINERY.—The duty of a coal operator to provide reasonably safe machinery and appliances in operations affecting his employees' safety does not end with the installation of safe machinery, etc. There is a continuing obligation to maintain a continuing oversight and inspection to avoid defects which may naturally be expected to arise from time to time. For example, the fact that brake shoes controlling the operation of cages in a mine shaft were safe when installed did not relieve the operator from liability for an accident occurring through a defective condition of the brakes afterward developed and permitted to remain so long as to raise an inference of negligence. (United States Circuit Court of Appeals, Eighth Circuit; Barrowman vs. Northern Central Coal Co.; 246 Federal Reporter, 906.)

PROVING NEGLIGENCE OF OPERATOR.—A coal operator, or other employer, is not to be charged with responsibility for injury to an employee on a theory of negligence in permitting some dangerous condition to exist, in the absence of proof that the employer knew or ought to have known of the defect in ample time to have remedied it before occurrence of the accident. On question being raised as to whether an operator was negligent in retaining an inexperienced jack setter to assist in the operation of a mining machine, resulting in injury to plaintiff, a member of the machine crew, it must be presumed, in the absence of proof to the contrary, that the jack setter properly inspected a mine roof before setting up a jack, although there was a fall of rock at that point when plaintiff, in the course of his duties, afterward removed the jack. (Missouri Supreme Court, Haggard vs. McGrew Coal Co., 200 Southwestern Reporter, 1072.)

TAXING MONTANA COAL DEPOSITS.—The provision in the Montana constitution that "the annual net proceeds of all mines and mining claims shall be taxed" applies to all mineral deposits and makes them taxable only when capable of yielding proceeds. But where an owner of lands conveys them, reserving underlying coal and the right to use the surface for the purpose of exploring and mining the coal, the fact that until development the coal would not be subject to taxation does not avoid taxation of the value of the surface rights reserved, they constituting a separately taxable interest in land. In such case, in determining the value of the reservation of right in the surface, the cash value of the land, less the underlying minerals, is to be ascertained as if the entire property were vested in one person, and an equitable apportionment made by the assessor between the grantee of the property, subject to the reservations, and the reserving grantor. (Montana Supreme Court, Northern Pacific Railway Co. vs. Musselshell County, 169 Pacific Reporter, 53.)

Increased Coal Storage Authorized

Increased storage of bituminous coal by consumers was authorized on Oct. 16 in regulations issued by the United States Fuel Administration. All classes of consumers, except Class 1, as defined by the War Industries Board, were authorized to increase their reserve stocks, and those heretofore not on the preference list were authorized to lay in additional reserve supplies. Consumers in Class 2 may store their coal up to the limits now imposed on Class 1. Consumers heretofore in Class 3 will receive the facilities heretofore accorded to Class 2, and consumers in Class 4 have been allotted the opportunities heretofore reserved for Class 3. Consumers not on the preference list are allowed the stocks formerly permitted Class 4 concerns.

The regulations, it was announced, will stand until further notice, and it was stated that, under them, an opportunity is afforded every industrial consumer for laying in at this time some reserve supply of bituminous coal. Regulations in detail are as follows:

CONSUMERS IN CLASSES 1 and 2.

Maine, 135 days.
Massachusetts, Vermont, New Hampshire, Northern New York, 105 days.
Connecticut, Rhode Island, Southwestern New York, 90 days.
Southeastern New York and New Jersey, 60 days.
Delaware, East Pennsylvania, Maryland, District of Columbia, Virginia, North Carolina, South Carolina, Georgia, Florida and Western Ohio, 45 days.
Western Pennsylvania, West Virginia, Eastern Kentucky, Eastern Ohio, 35 days.
Lower Michigan, 90 days.

CONSUMERS IN CLASS 3

Maine, 120 days.
Massachusetts, Vermont, New Hampshire, Northern New York, 90 days.
Connecticut, Rhode Island, Southwestern New York, 75 days.
Southeastern New York and New Jersey, 50 days.
Delaware, Eastern Pennsylvania, Maryland, District of Columbia, Virginia, North Carolina, South Carolina, Georgia, Florida, Western Ohio, 40 days.
Western Pennsylvania, West Virginia, Eastern Kentucky and Eastern Ohio, 30 days.
Lower Michigan, 75 days.

CONSUMERS IN CLASS 4

Maine, 105 days.
Massachusetts, Vermont, New Hampshire, Northern New York, 75 days.
Connecticut, Rhode Island, Southwestern New York, 60 days.
Southeastern New York and New Jersey, 40 days.
Delaware, Eastern Pennsylvania, Maryland, District of Columbia, North Carolina, South Carolina, Georgia, Virginia, Florida, Western Ohio, 35 days.
Western Pennsylvania, West Virginia, Eastern Kentucky and Eastern Ohio, 25 days.
Lower Michigan, 60 days.

Consumers not on the preference list are limited to the following stocks:

Maine, 90 days.
Massachusetts, Vermont, New Hampshire and Northern New York, 60 days.
Connecticut, Rhode Island, Southwestern New York, 45 days.
Southeastern New York and New Jersey, 30 days.
Delaware, Eastern Pennsylvania, Maryland, District of Columbia, Virginia, North Carolina, South Carolina, Georgia, Florida and Western Ohio, 30 days.
Western Pennsylvania, West Virginia, Eastern Kentucky and Eastern Ohio, 20 days.
Lower Michigan, 45 days.

There is no restriction on the stocks of screenings which may be accumulated by either preference or non-preference consumers, nor is there any restriction on the stocks of Indiana, Illinois or western coal which consumers in any class may obtain. Supervision of the accumulation of stocks in accordance with these limits will be exercised by the several State Fuel Administrators, who are authorized to make exceptions where special conditions make it necessary.

To Investigate Alaskan Coal Fields

To confer with officials of the Alaskan Engineering Commission relative to the coal resources of the Anchorage district and to make a personal inspection of the Matanuska field is the mission of a special Federal commission appointed by Secretary of the Interior Franklin K. Lane. The members of the Federal commission are E. O. McCormick, vice-president of the Southern Pacific R. R., chairman; George Watkins Evans, of the Bureau of Mines, University of Washington, Seattle, Wash.; George C. McFadden, chief engineer of the Chicago Coal Co., and L. A. O. Gabaney, geologist, of Chicago. The commission is now at work in Alaska.

Special Fuel Commission Named

Appointment of a special commission of the United States Fuel Administration to inquire into conditions and government regulations affecting the coal industry in foreign countries was announced on Oct. 15 by Fuel Administrator Harry A. Garfield. The commission will consist of Walter E. Hope, who joined the Fuel Administration on Sept. 19, 1917, as Director of the Bureau

of State Organizations; S. Brinckerhoff Thorne, of New York, coal expert, and James H. Allport, one of the engineers to the Fuel Administration. They will sail soon for Europe.

Mr. Hope went to the Fuel Administration from New York where he is a member of the law firm of Maston & Nichols. He is a graduate of the New York Law School, and of Princeton, where he was editor of the *Daily Princetonian.*

Mr. Thorne is a graduate of Yale, '96, and is president of the Temple Coal Co. and of Thorne, Neal & Co., coal distributors. At college he played three years on the 'varsity football and was captain of the team the last year. Since then his business has been coal.

Mr. Allport is a consulting engineer of national reputation. Prior to his connection with the Fuel Administration he was connected with many companies. He attended the University of Pennsylvania, taking special courses, and lives at Phillipsburg, Center County, Pennsylvania.

Railroads Moving More Coal This Year

An increase of 11.7 per cent. in the bituminous coal loading in the eastern region took place between Jan. 1 and Sept. 30 as compared with the corresponding period of 1917. This is based on a report to the Railroad Administration by A. H. Smith, the regional director. The percentage of increase or decrease on the various roads is as follows:

	Cars	Per Cent.		Cars	Per Cent.
B. & O.	115,985	31.0	N. Y. C.	188,287	2.8*
B. R. & P.	183,271	9.0	Penn. West.	463,706	21.0
Cent. Ind.	2,757	70.0	P. M.	8,633	5.0
C. I. & L.	31,433	28.0	P. & S.	43,567	3.0*
C. I. & W.	5,094	67.0	T. & O. C.	87,271	18.0
C. C. C. & St. L.	155,231	4.0	T. St. L. & W.	13,341	
D. T. & L.	8,559	1.6	Wabash	52,298	12.0*
Erie	24,537	1.0	P. C. & Y.	11,938	5.0
H. V.	107,642	11.0	W. & L. E.	70,492	29.0
K. & M.	58,479	2.7			

* Decrease.

Increase in the number of cars loaded in 1918, up to and including the week ending Oct. 5, over the corresponding period of 1917, is 682,112 cars. Coal loaded by all roads during the week ended Sept. 28, and compared with corresponding week of 1917, is as follows:

	1918	1917
Total cars bituminous	226,345	190,467
Total cars anthracite	40,524	42,008
Total cars lignite	4,040	3,679
Grand total cars all coal	270,909	236,154

A summary of reports for week ended Oct. 5, 1918, based on actual reports from most roads, but with the results of some roads estimated, follows:

	1918	1917
Total cars bituminous	209,432	186,699
Total cars anthracite	38,550	42,079
Total cars lignite	3,452	3,122
Grand total cars all coal	251,434	231,900

One of the most promising features of the car situation, as it applies to movement this winter, is the fact that 31,794,000 cars of grain had been moved up to Oct. 1, as compared with 4171 cars for the same period of last year.

A review of the coal budget is to be made by the Fuel Administration, in light of the six-months' figures. Some realignment of tonnage will take place.

Anthracite Shipments for September, 1918

The shipments of anthracite for September, as furnished to the Anthracite Bureau of Information, amounted to 6,234,395 tons as compared with 6,372,756 tons for September last year and 7,180,923 tons for the month of August this year, showing a decrease over September of last year of 138,361 tons, and a decrease as compared with August this year of 946,528 tons. The small production in September as compared with August is due principally to the fewer number of working days last month; five Sundays and one legal holiday (Labor Day) reducing the number of working days in September to twenty-four, whereas there were twenty-seven working days in August.

The average daily shipments in September of this year were 259,766 tons against 254,910 tons for the corresponding month of last year, a record which, considering labor conditions at the present time, indicates that the anthracite industry is not laggard in its duty to the Government and the public. The shipments by companies were as follows:

	September, 1918	September, 1917	Coal Year, 1918	Coal Year, 1917
P. & R. Ry.	1,231,435	1,246,100	7,996,029	7,562,874
L. V. R.R.	1,167,784	1,258,922	7,694,157	7,370,946
C. R.R. of N. J.	571,147	559,581	3,574,745	3,536,845
D. L. & W. R.R.	927,608	973,529	6,071,574	6,214,638
D. & H. Co.	736,497	698,731	4,775,049	4,471,142
Penna. R.R.	433,068	422,482	2,866,556	2,869,645
Erie R.R.	703,363	717,129	4,587,653	4,556,139
N. Y. O. & W. Ry.	157,387	155,886	1,045,026	1,018,010
L. & N. E. R.R.	306,106	340,396	2,012,602	2,069,626
Total	6,234,395	6,372,756	40,623,391	39,669,865

Influenza Affects Coal Output

Coal production will be cut down 5 to 50 per cent. in the various producing districts by the influenza epidemic, according to reports reaching the Fuel Administration. It is believed, however, that the higher figure mentioned hardly is a conservative estimate. Nevertheless, the Fuel Administration is taking no chances. James B. Neale, the director of production, has been authorized to open temporary hospitals wherever it is practicable.

Brief Washington Notes

Suspension of automobile, motor-cycle and motor-boat racing for the period of the war has been requested by the Fuel Administrator.

To assure the Senate that he approves of liberal account being taken of depletion and the extra hazard in coal mining, Dr. Garfield appeared before the Finance committee Oct. 15. The session was executive.

A new set of coal zone orders, which will consolidate all the summer's modifications and changes is soon to be issued by the Fuel Administration. Owing to the multiplicity of separate modification orders difficulty often is experienced in keeping up with them all.

Collection of reports of mining engineers in the course of its war work made clear to the Bureau of Mines the great value of having such technical and economic information on file at all times. As a result the Bureau has begun a systematic effort to collect all such reports available. A file also will be maintained of the quarterly, annual and other reports of mining companies.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The anthracite wage problem has not yet reached complete solution though that may come at any time. The proposed wage schedule will be found with appropriate comment on page 789 of this issue. Meantime the production of coal is proceeding smoothly in the anthracite region. No labor troubles are now occurring and the only interference with output arises from the influenza. Minersville, in the Southern field, is so grieviously afflicted that it has been necessary to call on the Army Ambulance Corps at Allentown, 51 of the army surgeons from that city having been obliged to locate in and about that section.

Central Pennsylvania production has been checked by two adverse influences—the victories in France and the Spanish, or should it be the German, influenza. As for the victories, they have been enthusiastically followed by the mine workers of the Keystone State and the miners were so much impressed by the importance of the Allied advances that they were quite prepared to hear that the Kaiser had surrendered, so prepared, indeed, that when the rumor circulated that the long-hoped-for event had occurred they not only ceased buying Liberty Bonds, but left the mines to celebrate. Unfortunately the story was not true and was made only the less likely by the untimely celebration. By the premature closing of the mines the time when the Kaiser will be "smothered with coal" becomes only more remote.

The cause of the trouble is declared to be German propaganda, but unfortunately it is not necessary to imagine any such source. The story was already in the minds of everybody, ready to be given spread and credence. There is altogether too much of a disposition to believe that the battle is over. A little reading of British and American casualty lists and the account of U-boat activity will act as a corrective for such excessive optimism. The Germans are not yet beaten. It is still not impossible that the British will so far outrun their artillery that the Germans will be able to turn on them as the French turned on the Germans at the Marne.

Courtesy "American Coal Miner"

THEY ARE NOT HOISTING BOOZE—BUT COAL

The Germans by their apparent yielding did the Liberty Loan sale no little injury and shut down several mines. In Winber alone the loss in production of the Berwind-White Coal Mining Co. was 6000 tons. Along the Southfork branch near Johnstown, Penn., there was a loss of 4000 tons. The Portage branch in the same vicinity produced 2000 tons less fuel. At Ehrenfeld, Nanty-Glo, Beaverdale and other operations of the Pennsylvania Coal and Coke Co. the idle mines failed to produce their regular quota of 3000 tons per day. These are only a few of many mines affected. The action of the miners was widespread, and operators would do well to warn everybody in authority against spreading rumors about Allied success unless it is duly verified from Washington.

A number of excellent suggestions regarding the combating of Spanish "flu" have been spread broadcast by the Central Pennsylvania Coal Producers' Association. It might be well to add a few others: Avoid facing any person too closely when talking. Some people have an unpleasant way of crowding their faces into the faces of their friends when trying to enforce an argument. It is a rude and dangerous habit at any time and it is worse now than ever.

SHOULD AVOID COMMON TOWEL AND WASHBOWL

Avoid the use of the common towel. Your own manners may be cleanly, but you cannot tell how others have acted in using that public utensil. Avoid the common washbowl unless it has been sterilized or properly scalded. Some men make a practice of cleaning their nasal passages when washing, and merely pouring out the water does not cure the evil. The scum found on the sides of every washbasin shows that such cleansing is inefficient.

Where pillows are removed from beds for sunning and ventilation—and the practice is surely to be recommended—their exchange should be avoided. Every effort should be made to let every person have his own pillow, his own towel and his own washrag. Someday we shall not only have them, each for himself, but we shall have them properly marked so that identification will be unquestioned.

We should be wary of everyone. The "cured" may carry the germs. The fact that they are well may only show that they have built up a defense. They are not harmed any longer by the germs, but that is because they have the power to counteract any evil influence they might have on the person harboring them. It does not show that the germs are destroyed or incapable of infecting other persons. "Typhoid Mary," in perfect health, harbored typhoid germs for years and infected all who came in contact with her. She was finally interned.

PENNSYLVANIA SUFFERS FROM GRIP AND ALIENS

In seven places in central Pennsylvania the mines have been closed by influenza while as many more have had their production cut as much as 50 per cent. The mines closed were those at Wishaw, Eleanora, Florence, Soldier, McIntyre, Coal Run and Conifer. Ernest, Finleyville, Clymer, Dixonville, Rossiter and the Broad Top regions were operated with greatly reduced forces.

The people of central Pennsylvania and especially the miners are determined to exclude from the mines the unpatriotic enemy aliens who will not mine coal and are trying to make trouble. The Pennsylvania State Constabulary at Punxsutawney will help in the roundup. Samuel Lakatosh, an Austrian enemy alien, employed at the Potts Run Land Co.'s mine, at Boardman, was placed under arrest by Constable Thomas B. Reilly, of Clearfield, after a running revolver fight. This man mined only 16 tons for the month ending Sept. 21—about three ordinary days' work. He spent his time, not in mining coal, but in visiting his fellow aliens, declaring to them that they "had no business

getting out coal to kill their brothers in Austria." Personal notice is being served on some 300 or 400 Austrians that they must report regularly for duty and get out a full day's output or they will be interned.

The wage increases of the New River and Winding Gulf regions, granted at the close of last year, were based on the irregularity of the miner's opportunity to work. The mine workers readily saw that the increases should go only to those suffering by that irregularity. They were quite content that the "monthly men," who were paid as much whether the mines worked or were idle, should receive the same wage as before. But times have changed. The railroads are supplying all the coal cars needed, and the day worker now gets as steady work as he desires and quite a little more than some of the less diligent would wish to receive.

The monthly man, who was fortunately situated before, now feels he is discriminated against. The increase which was granted for the short time suffered by the day man, in his belief, is the right of the monthly man also. Thus wages climb steadily upward on the inequalities of our industrial situation. The mine workers of District No. 29, which embraces the New River and Winding Gulf districts, at a special convention held Oct. 8 at Beckley, passed a resolution notifying the operators that they would strike if the full wage increase of $1.40 a day were not granted to monthly men.

Monthly Men Want Increase of Day Men

So far there has been no strike and a vote on the question of striking is said to have resulted unfavorably to any such action. However, just consideration should be given to the increased cost of living, and the monthly men might well be granted an increase if it can be shown that they are entitled for this reason to an increased emolument. The shortage of miners has in most cases increased the "turn" in the mines so that not only more days' work are secured but more tonnage is put out per day worked. The contract miner is in clover and the monthly man should not be dieted on thistles.

The miners contend that under what is known as the "Washington agreement," as it was adopted at a conference November, 1917, the words "monthly men" were not inserted in the form in which they appeared in the original Washington agreement. The mine workers contend that the operators have taken advantage of this variation in phraseology and have refused to pay the advance of $1.40 a day to monthly men.

West Virginia is fast becoming unionized. It was formerly the stronghold of the nonunion operator. Now there are few parts without union locals. The change in the Fairmont (W. Va.) region has extended now to those mines in Kentucky owned by the Fairmont interests—the Consolidation Coal Co. Vice-president Petry of District 17 has just returned to Charleston from the Big Sandy section of Kentucky, where he spent several days recently. He organized on his trip the mines at Auxier.

Patriotic Miner Earns $716 in a Month

The largest wage paid in Monongalia County to any coal miner was probably that paid during the month of September to Lawrence Finzel by the Hartman Run Coal Co., whose mines are near Sabraton. The payroll of the company shows that he received $716.40 for the month of September. He loaded 417 cars or 730 tons during the month. In the first half of the month he loaded 201 cars and earned $281.40. In addition he earned $57 for labor performed Thus he received a total of $338.40 for the first two weeks in September.

In the last half he loaded 216 cars, earning $378, thus making the grand total — "grand total" is right — of $716.40. If he keeps up the rate Finzel will make $8596.80 a year, an annual income which few industrial managers can duplicate.

The miners of the United States Coal and Coke Co., on Tug River, are not content with the regular day's run. For three successive Saturdays these men have gone back to work after supper, and the result of their patriotic work has been the shipping to market of 20,900 tons more than would have been shipped had this sacrifice not been made. When one thinks how men look forward to Saturday, their sacrifice appears almost heroic. If you would visualize the result of the patriotism perhaps it can best be done by remembering that the output made by this overtime work would fill 418 railway cars of 50 tons capacity.

Reports of large earnings also come from the West. John Crawford, the state inspector of coal mines in Utah, states that the average wage in the mines of Carbon County will run between $10 and $15 a day. At present the men are working six days a week. A few exceptional men at the Black Hawk and Standard mine in July and August made each month as much as $455, $460, $530 and $533 for machine work. Under normal conditions it was exceptional for a man in Carbon County to make $100 a month. Now quite generally men are receiving $250 a month and even more. The shifts are only of 8-hour duration. The data at present available show that there is no probability of any shortage of coal in the region served by the Carbon County fields.

Must Have Good Houses for Mine Men

The drive to secure men at the mines, in which the union is participating, has moved Walter Nesbit, secretary and treasurer of District 12 of the United Mine Workers, (Illinois, in other words) to protest against overlooking the housing provisions whenever men are being sought. He does not believe that there is much need for a campaign when housing facilities are good, and the dwellings are as attractive as they are around Springfield. He suggests that the United States Employment Service should inquire into this matter when preparing to secure men for a plant.

"You cannot expect men to bring their families to live where there are no adequate housing accommodations," he said. "Even when they have no families, men who work

Courtesy of "The Retail Coalman"

LABOR MUST STAY, FOR COAL IS VITALLY NECESSARY

as hard as miners need to be decently housed. Men will not go to work where they have to live in tents and mine bunks if they have the opportunity to live where they can get better housing conditions."

Nesbit said an application has been made to him by an operator whose mine was at a distance, asking for a large number of miners, but when he found that the men would have to live in tents he would have nothing to do with it. But Nesbit and the other union officials will coöperate fully with the Government in its efforts to get former miners back into the mines. The efforts in the drive are to be concentrated mainly on that class. The many men who have left the mines in recent years will be reached through the unions and will be urged to return to the mines and remain there until the war has been won.

Anthracite Wage Increase Proposed

On his return from Washington, Oct. 12, James Matthews, president of District No. 9 of the United Mine Workers of America and hence a member of the Anthracite Conciliation Board and a member of the board which was formed to suggest the terms of a new wage scale, revealed the nature of the contract which had met with the approval of the latter board. This contract is to be submitted to a committee composed of the various War Labor Boards and then to Dr. H. A. Garfield, the United States Fuel Administrator. It seems quite sure of approval by both of them, and the scale will doubtless become operative if the mine workers do not oppose it as containing less than they desired in the matter of wages and pay for overtime.

The recommendations mentioned are as follows and are placed in juxta-position to the terms of the contract of Nov. 17, 1917, so that they may be readily compared:

Proposed New Anthracite Wage Agreement

a. Contract hand and machine miners shall be paid an advance of 40 per cent. on their gross earnings. b. Consideration miners shall be paid an advance of 25 per cent. plus $1 a day for each day worked. c. Contract miners' laborers shall be paid an advance of 40 per cent. on their earnings. As this increase of 10 per cent. over the agreement of Nov. 17, 1917, is less than $1 per basic shift, the difference between said increase of 10 per cent. in the rate and $1 per basic shift shall be assumed by the operator. d. Consideration miners' laborers shall be paid an advance of 25 per cent. plus $1 a day for each day worked. e. Day machine miners' laborers who received not less than $2.72 per day shall be paid an advance of 25 per cent. plus $1 per day for each day worked.

f. Outside blacksmiths, carpenters, electricians, machinists, foremen, hoisting engineers on shafts and slopes where employment is limited by law or by the award of the Anthracite Coal Strike Commission to 8 hours a day and engineers working on a 12-hour shift basis shall be paid an advance of $2 a day for each day worked. All other outside company men who received $1.54 or more per day, shall be paid an advance of $1.80 a day each day worked. g. Inside engineers and pumpers working on a 12-hour shift basis shall be paid an advance of $2.20 per day for each day worked. All other inside company men who received $1.54 or more per day shall be paid an advance of $2 per day for each day worked. h. All employees paid by the day who received less than $1.54 per day shall be paid an advance of $1.20 a day for each day worked.

i. Monthly men coming under the agreement of May 5, 1916, shall receive an advance per day for each day worked equivalent to that provided for their respective occupations under paragraphs f and g.

j. The advance of $2.20 a day, $2 a day, $1.80 a day, $1.20 a day and 25 per cent. plus $1 a day, provided above, are to be applied to a day whether 8 hours or more, as established under the agreement of May 5, 1916. Any proportionate part of a day to be paid a proportionate part of the advances herein provided.

k. The employees of stripping contractors paid by the day, working on the basis of a 9-hour shift, shall be paid the same increase per hour worked that is provided for outside company men working on an 8-hour basis.

The new scale provides an increase to contract hand and machine miners of 12 per cent. over the contract of Nov. 17, 1917. Consideration miners get an increase of $1 per day. Contract miners' laborers get an increase of 7.692 per cent. but as this is less than $1 per day, an increase of $1 is assured them. Consideration miners' laborers get an increase of $1 per day and so do such machine miners' laborers as received not less than $2.75 a day under the contract of May 5, 1916.

Outside engineers working a 12-hour day put a dollar more daily into their pockets. Outside blacksmiths, carpenters, electricians, machinists, firemen, hoisting engineers on shafts and slopes, where employment is limited by law or by the award of the Anthracite Coal Strike Commission to 8 hours a day, receive an increase of $1.10 a day. All other outside company men who got, under the contract of May 5, 1916, $1.54 or more per day ($2.54 under the contract of Nov. 17, 1917) now receive 90c. a day more than under the contract of Nov. 17, 1917.

Inside engineers and pumpmen working on a 12-hour shift get $1.10 more per day than under the agreement of Nov. 17, 1917, and all other inside company men who under the contract of May 5, 1916 received $1.54 or more per day ($2.54 under the contract of Nov. 17, 1917) now get $1 more per day than under the contract of Nov. 17, 1917. All day men who under the contract of May 5, 1916, received less than $1.54 a day ($2.14 under the contract of Nov. 17, 1917) get an increase over and above the contract rate obtained under the contract of Nov. 17, 1917 of 60c. per day.

The revisers of the old contract seemed to have approached the matter in a commendable spirit. The anthracite miners had a degree of justification in their demand for a better wage, if for one moment the fact be overlooked that they were bound by a contract that could not be broken without a breach of faith. It must be conceded that the scale was much lower than in the bituminous region and in many cases so much lower that it was impossible to explain the fact away satisfactorily by calling attention to the great inequality in the regularity of operation normal to the two mining regions. The old contract is as follows:

Anthracite Wage Contract of Nov. 17, 1917

a. Contract hand and machine miners shall be paid an advance of 25 per cent. on their gross earnings. b. Consideration miners shall be paid an advance of 25 per cent. on their earnings. c. Contract miners' laborers shall be paid an advance of 30 per cent. on their earnings. d. Consideration miners' laborers shall be paid an advance of 25 per cent. on their earnings. e. Day machine miners' laborers, who received not less than $2.72 a day, shall be paid an advance of 25 per cent. on their earnings.

f. Outside engineers working a 12-hour day, cross-shift and firemen shall be paid an advance of $1 a day for each day worked. All other outside company men, who received $1.54 or more a day, shall be paid an advance of 90c. a day for each day worked. g. Inside engineers and pumpmen, working a 12-hour cross-shift, shall be paid an advance of $1.10 a day for each day worked. All other inside company men, who received $1.54 or more a day, shall be paid an advance of $1 a day for each day worked. h. All employees paid by the day, who received less than $1.54 a day, shall be paid an advance of 60c. a day for each day worked.

i. Monthly men coming under the agreement of May 5, 1916, shall receive an advance per day for each day worked, equivalent to that provided for their respective occupations under f and g.

j. Advances of $1.10 a day, $1 per day, 90c. per day and 60c. per day, provided above, are to be applied to a day, whether eight hours or more, as established under the agreement of May 5, 1916; any proportionate part of a day to be paid a proportionate part of the advances herein provided.

k. The employees of stripping contractors, paid by the day, working on the basis of a 9-hour or 10-hour shift, shall be paid the same increase per hour for each hour worked that is provided for outside company men working on an 8-hour basis.

Importance of Spreading Safety Work

AS A result of the well-attended and well-managed Congress of the National Safety Council in St. Louis, safety in that city made remarkable progress. It will be remembered that the meeting lasted from Sept. 16 to Sept. 21. It was a remarkable week, with an unbroken record of security from fatal accidents, except when an intoxicated man fell from his wagon into an excavation. That was the only death from accident in St. Louis, East St. Louis, Madison, Granite City and Venice in the week lasting from 8:30 p.m. Sept. 14 till 12:15 a.m. Sept. 22—a remarkable record in view of the great business activity which the pressure of the war has engendered.

Just a year before, in those same cities, 24 lives had been lost from accident within a single week. In the week before the Congress met ten lives had been the toll from that cause. In the whole year 1917, 510 lives, an average of nearly ten a week, had been taken by accident. Yet in the entire week of the Congress but one life was lost.

The week was dubbed "Safety Week" by proclamation of the mayors of the five cities. The newspapers, within the limits permitted by the United States Government, which is trying to save print paper as well as lives, gave the safety movement admirable support. They could not print extras, or they would have done so; for they had made preparations to give the movement that kind of publicity.

It was heralded far and wide that the week of the Congress was to be a "No Accident" week. At all the schools, public and parochial, talks were given on safety. Every child took home a letter relating to accident prevention and a bulletin proclaiming the same good story. The churches preached safety; the Roman Catholic Archbishop of St. Louis advocated it in a pastoral. The police force had daily drills to emphasize safety and were for the first time assembled for a talk about the importance of that part of their duties. It is quite likely that these 1600 men, who were enthusiastically behind the movement, had much to do with its success.

There were moving-picture exhibitions advocating safety in the many parks and recreation grounds of the city. It is said that 100,000 workmen and their families saw these pictures, and at the moving-picture houses at least 50,000 persons saw the safety films. The 40,000 owners of automobiles received a letter on the need for caution, and with these letters went safety stickers for the wind shields of their conveyances. A half million pay envelopes with safety mottoes were used during the week by employers in paying their men. The fire department also gave exhibitions which stimulated the general interest. At all the clubs which met during the week, and some met on purpose, addresses were given on safety. The large civic clubs—16 in all—were thus approached in the safety campaign.

St. Louis thus received safety, not in the unwelcome guise of an admonition from a self-righteous employer, but as part of a great national campaign. It came to the St. Louisan and to his wife and children as a movement of his own. And he embraced it. It went to his home. He heard it from his wife and from the lips of his child; he was confronted with it when he went to worship on Sunday and when he met with his friends at his favorite club during the week.

In the mining districts we cannot get "Safety First" if we treat the problem as a cold business proposition. It must not only be given the touch of nature which makes us all akin, but it must be made universal. The words "Universal Safety," which appear on the seal of the National Safety Council, express the idea well. We cannot get real safety so long as we keep our efforts narrowed to the straightened limits of the plant.

It must go all through the mining village; it must take in every one, male and female, young and old, and it must include every occupation in which any of the habitants are engaged. It must come at every angle and radiate from every center—office, surface plant, mine, church, school, club and press. Some are best approached in one direction, some in another. Let the employer be broad, and remember that the worst form of propaganda is the direct approach from employer to employee. Yet despite its imperfections, the more direct course is the one easier put in operation and therefore has the greater advantages. But while seeking safety of the employee by direct methods the indirect method of interesting everybody and creating a universal spirit of safety should never be overlooked.

Cold-Weather Instrument Work

DUE to the effect of varying temperatures on transits and levels during cold weather, many an hour is lost in winter surveying work. When the transitman enters a mine the instrument is often at a temperature well below zero. As a result, a heavy sweat which turns to hoar frost breaks out all over the instrument; or, to speak more correctly and so satisfy purists, the vapor in the air condenses on the cold surfaces of the instrument and promptly congeals.

This sweat beclouds the object glass and eyeglass, and sometimes even gets between the double lenses of which the object glass is composed. This causes no little delay. A long sight through the inevitable fog on the glass is difficult or impossible, and the transitman is prone to put his instrument to one side while he does other work or "joshes" the men on the job until such time as the transit has reached a temperature more nearly approximating the temperature of the mine workings.

Perhaps he tries to clean the lens. This is a job that seems endless, for the temperature of the lens being

only slowly bettered the mist settles on it as fast as the moisture is removed. If the instrument man has set up his instrument, traffic on the road is suspended, and the working forces of the mine are delayed to little or no purpose.

But the cleaning of the lens may have a worse effect. All rags and cloths taken into a mine are apt to be dirty, either from the slate and coal dust which fall from the roof and rib respectively into the surveyor's pocket, or from the dust flying in the air, or, in the case of a handkerchief, from the dirt and dust rubbed from the face and hands. If a silk rag, a chamois skin or a banknote be used, the damage to the lens may be, it is true, so small as to be immaterial. But a dirty linen or cotton cloth is almost sure to scratch the lens when used for its cleansing. A few such cleanings, and the clarity of the lens is markedly destroyed.

The moisture, moreover, settles all over the instrument and lights on the graduations. These also are easily scratched, if wiped by an uncleanly rag. Furthermore, if the water were just pure water, it would not be so bad. It seems likely that it is rarely pure in mines where explosives are being fired and the air is full of smoke. Because of this smoke it is usually acid water, and it tends therefore to corrode the instrument. An unprotected vertical arc soon becomes almost unreadable, and even the effect on the horizontal limb is quite noticeable.

But there are other sad possibilities. The water gets between the horizontal plates, and if it does not dry before the transitman comes out of the mine the plates will freeze together, or at any rate enough ice will form between them to make their relative movement difficult. If, then, the transitman wants to measure an angle when he reaches the surface, he finds it either impossible or difficult. At times the instrument would rather screw off at the head than turn in the manner designed. It then becames necessary to light a fire or go into some house and warm the instrument before a stove.

In the house the steaming kettle has probably filled the air with moisture, and again the transit is coated with a film of liquid; and even if it does thaw out, it is no sooner asked to officiate than it freezes again and the situation is unchanged. Back to the house goes the transitman with his little train of aides.

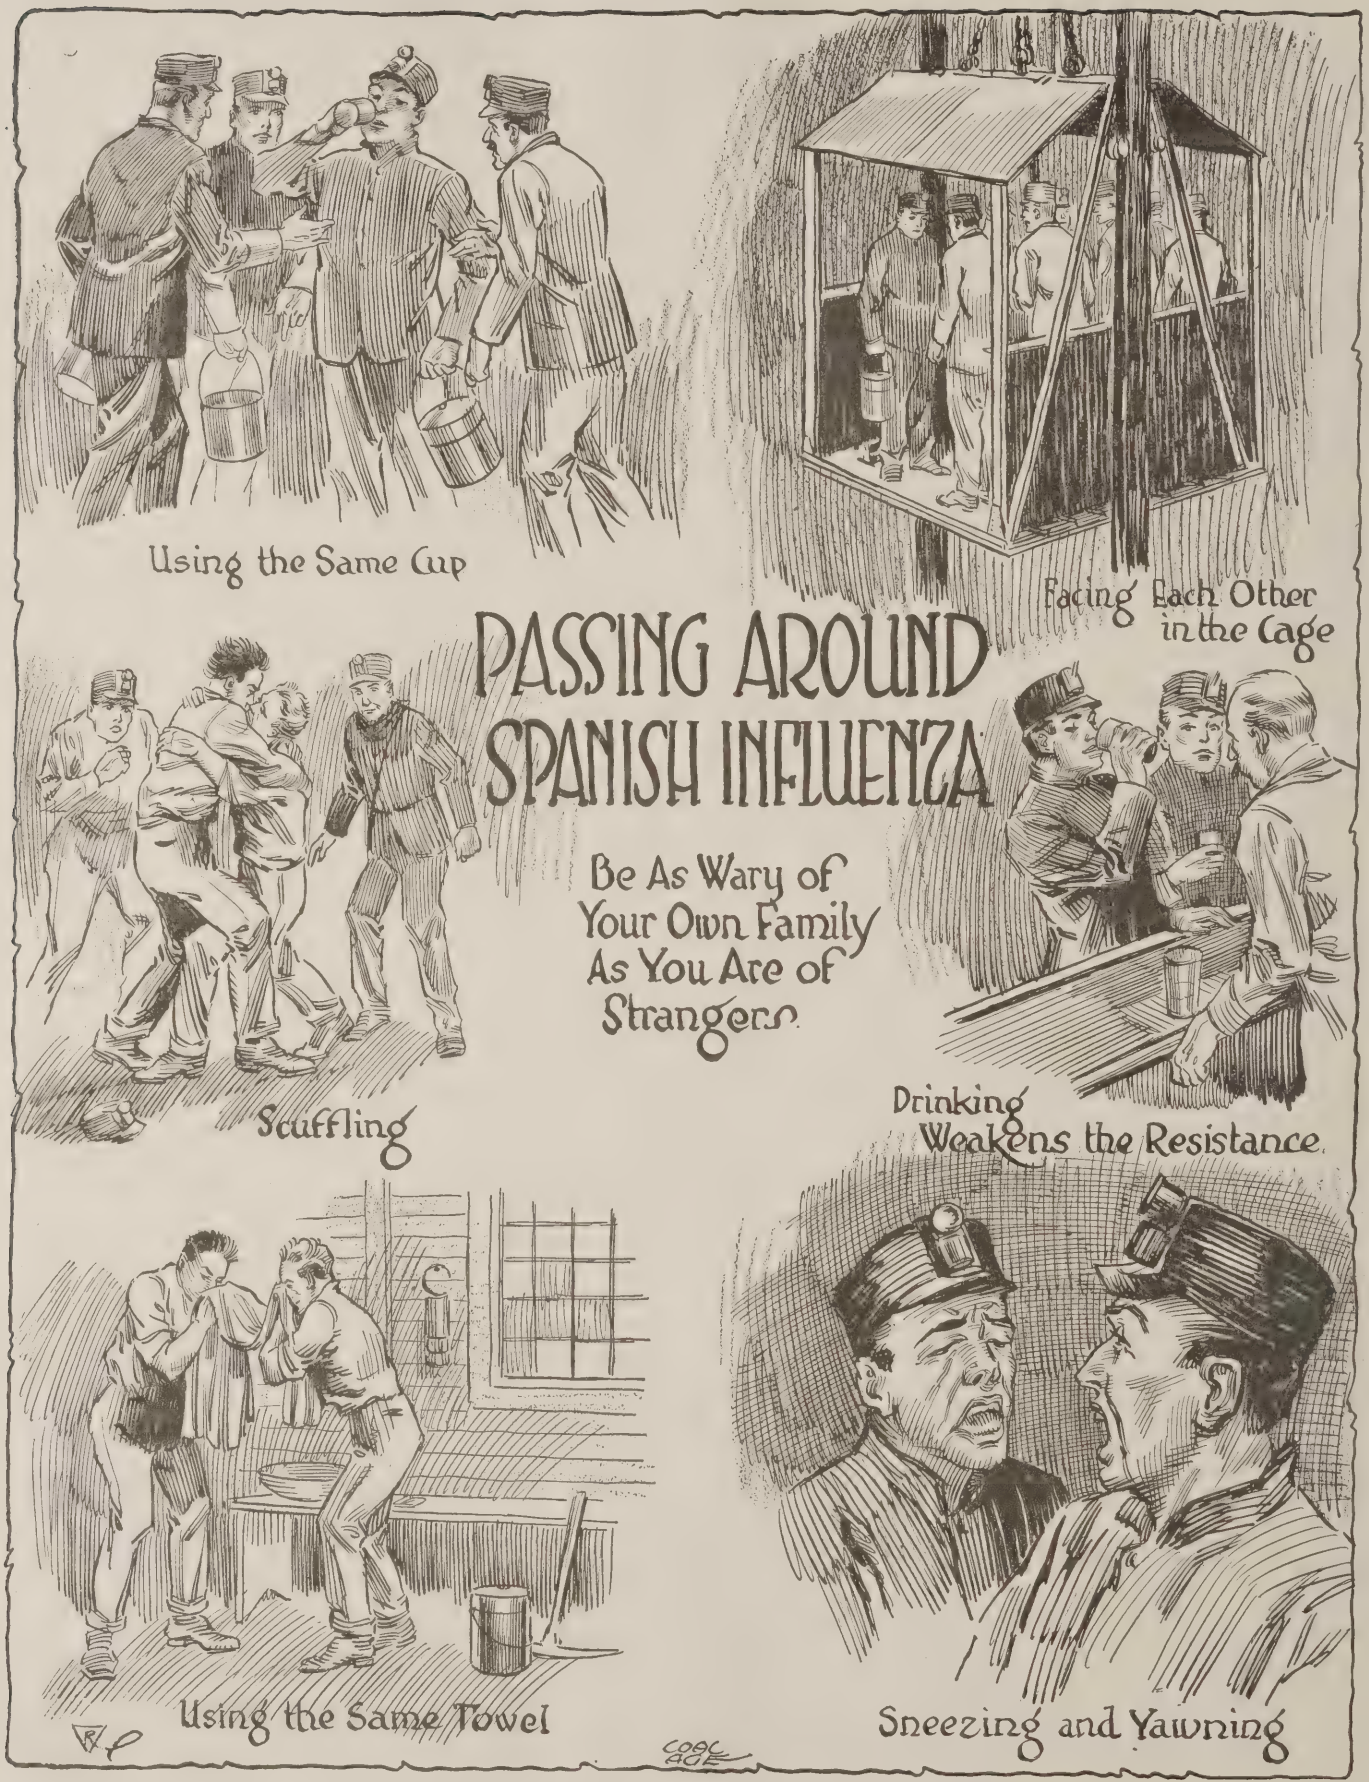
This is all very well if the instrument man likes a warm spot, if he is not anxious to get his work done and if his company is cheerfully willing to put up with the situation. But transitmen are not always so disposed. They are busy men, and often work late at night and till the early morning; and even when they do their best they are regarded as abnormally slow.

So a little thinking on this difficulty would surely be well worth while. An instrument should never be allowed to get unduly cold on its way to the mines even when a long trip has to be made. A quilted hood should be provided for it, and even then this should be warmed before a start is made. The hood should be tied tightly about the tripod head so as to exclude the cold air. This hood would also serve to protect the instrument against dust.

The instrument will undoubtedly get cooled on its way to the mines, and if by chance it is cold enough to sweat, the best plan is to seek a warm place as soon as the work is reached. A warm, smokeless heading on the way to work is usually available, or some old working where decaying timber raises the temperature above the normal. It is useless to hold up the regular mine work by a chilly instrument which will not operate. The instrument man can usually find some work to do while the instrument is reaching a normal temperature, especially if he has planned his work before leaving the office.

Instruments quite frequently get wet from rain and melting snow. Every opportunity should be taken during cold weather to dry them out. Otherwise the plates and the screws, both for leveling and adjusting, will become gummed and the result will be that time will be lost. There is often far too much haste to get away in the morning. An instrument, warm and properly protected, is a *sine quâ non* for a good day's work in the mine.

The tendency of an instrument to become covered with moisture on entering a warm room and so to be unruly when taken out to work, if in the meantime it does not get dried out, furnishes a reason for tightly covering an instrument with a quilted hood before entering the office. A stand in which the instrument can be placed without boxing is, therefore, to be strongly recommended.



It does not seem orderly to use such a stand, but it is certainly better than to box a damp instrument or one that is dried out only exteriorly. In any event the boxing of a transit is at best a severely jolting operation and somewhat hard on the adjustments. Thus it is apt to affect them as badly as running with an instrument over the shoulder.

"Seeing the Boss" Wastes Time and Temper

WE HAVE long ago become accustomed to seeing idle miners in our trips around the mines. It seems quite natural on passing a room to find a disconsolate digger waiting for cars, or for the air to clear, or hunting the driver in the hope that he may get rails or props on the next trip. Some miners, there still are, who do not go home when the trip runs slow, but wait patiently for an opportunity to work.

In many mines the miner can see the boss only in the morning or in the evening, at both of which times that dignitary is little disposed to listen because he is too busy. For this reason, the miner often comes out during the working day to see if he can, by some means, get an interview and secure an understanding. But more often he comes out at that time because only on reaching the face is he confronted with the actual conditions of his work. The place has perhaps become flooded from a neighboring room. His tool box has been broken open and his carbide stolen. A big fall of rock has made it impossible to put cars at his working face. So he comes out to see the boss.

Where this trip is a mile or a couple of miles each way, it is a great waste of time, even should the boss be found without difficulty. Now, every superintendent knows how hard it is to secure a liaison with a foreman even when he is willing to be found, but it is far harder for a miner to find a foreman when that foreman is anxious to avoid an interview. This seeing the boss is a great waste of time and temper under the conditions too often obtaining.

COAL AGE

DISCUSSION BY READERS

Perplexities of Mine Foremen

Letter No. 2—With much interest I read the letter that appeared in *Coal Age,* Oct. 3, p. 656, dealing with a few of the perplexities of mine foremen. Surely, that official is sorely perplexed at times by little matters that it is beyond his power to control.

Taking advantage of the present situation in the coal field, many miners think that they are entitled to hold up the mine foreman for all that they can secure from him, and then some. Their patriotism does not prevent them from ceasing work for two or three days because of some trivial matter that calls for a little extra exertion or labor on their part. As a result, probably 30 or 40 tons of coal are lost to the daily output of the mine. They take this course, instead of working on, and allowing the matter to be adjusted in the proper manner.

The miner, today, is in a position to make more money than at any time in the history of the coal industry. It would seem, however, that the more some miners are paid for their work, the less willing they are to perform their share and keep things moving. The following incident that occurred recently at a mine in this district illustrates how a very small matter can interfere with the regular operation of a mine when a miner fails to put up with a little inconvenience on his part and do his share to keep the coal moving.

In the instance to which I refer, the machine runner had encountered a small roll when cutting the coal at the face of a room. Like the good cutter that he was, when starting to make another cut, he raised the cutterbar a few inches to avoid the roll. This left 4 or 5 in. of bottom coal that was not cut. When the miner entered his place the next morning, almost the first thing he saw was the thin layer of bottom coal that had not been cut. He at once started for the mine foreman and demanded that the cutter should return and cut out the coal so that he could lay his track, refusing to shoot down the coal if this was not done.

The foreman was at first surprised to see the condition of the place, but, on closer examination, discovered the roll and explained to the miner that the reason the cutter had not cut the bottom coal was to avoid running into the roll and breaking his machine. The foreman offered to pay the man for two hours' extra work for each cut if he would dig up the bottom coal enough to lay his track.

The miner seemed willing enough to do this for the pay offered by the foreman, but said that he would first have to see the committeeman who worked in the next place to him. Now, this particular committeeman had formerly run a machine, but had been taken off for indifferent work. The union, also, had elected him on the Production Committee for that mine, which gave him an idea of his own importance. He advised the loader not to touch the bottom, saying that he would see that it was taken up by the cutter. This, however, the foreman flatly refused to have done.

When the matter was referred to the Mine Committee, they decided that the loader was offered a fair price and should take up the bottom himself. Nevertheless, the committeeman previously mentioned induced the loader not to do this, and the matter was then brought to the notice of the Production Committee. At a meeting held in the mine office, the committee was informed that, owing to the difficulty, the mine was losing six cars a day. After hearing the case, the committee decided that the foreman was in the wrong, which was promptly denied by that official.

The superintendent, not wishing to delay longer in the matter, then took the loader aside, who, after a few minutes' talk, went back to his place. In one hour, the man had dug up the bottom and had his track laid ready to load his coal. For that work he was allowed four hours' pay.

Only recently, I attended a meeting of the Production Committee of the Indiana County mines, and listened to an address by Chas. O'Neill on production. In the course of his remarks, he stated that he wanted everybody to get a square deal. He insisted that the blame for non-production should be placed where it belonged, whether the fault was with the operator, the mine foreman, or the miner. He repeated that a mine foreman should get a square deal, when a voice in the audience rang out, "It can't be done." Few who are familiar with conditions existing in the mines today will deny the truth of this statement.

MINE FOREMAN.

Homer City, Penn.

Iron vs. Wood Mine Cars

Letter No. 1—Kindly permit me to give a little of my own experience in reply to the request for the opinions of readers in regard to the relative advantages of iron and wood mine cars. I have been connected with the mining of low coal for a number of years and can say, from actual experience, that the iron mine car is far superior to the wooden car, in every respect.

It must be admitted that the iron car is much more expensive in the beginning, but my belief is that it will always be found cheaper in the end. When an iron car is worn out, and is no longer of any use in the mine for hauling coal, it need not be thrown aside as having no value. The iron of the car body can often be used to advantage around a mine, or it can be sold as scrap iron for a fairly good price.

IRON CARS OPERATED IN LOW COAL

About eight years ago a company opened up a slope mine in a seam of low coal. They equipped this mine with 100 cars, among which were three made entirely of steel. The records show that during the eight years of continuous service not one of these three iron cars has ever been sent out of the mine for repairs and all of the three are still in use, doing good service. About

two years ago the same company placed an order for 100 more cars, and decided to make this order for iron cars only, the decision being based on the previous service of the three iron cars still in use.

Because of the way in which an iron car stands up under the severe service to which cars are subjected in the mines, less lost motion is developed and the haulage locomotive is able to handle a much larger number of cars than is the case when wooden cars are employed and these have been in use a short time. Moreover, iron cars are not derailed as often as wooden ones, because they are less liable to get out of line. The running gear of a wooden car that has been used but a short time is far less rigid than that of an iron car after the same service, and the car is more liable then to jump the tracks at a bad joint or on a sharp curve in the road. Again, it is necessary to inspect wooden cars more frequently and send them to the shop for repairs as quickly as any weakness develops, while an iron car will stand the same rough usage without showing any such weakness.

Iron Cars Possess the Important Advantage Of Being Dustproof

One advantage of iron cars over wooden cars is the fact that they are generally dustproof. If the oak used to make the wooden cars is not thoroughly seasoned it will shrink in use and the car will develop large cracks that permit the dust and fine coal to be scattered along the road. Another source of trouble, in the use of wooden cars, is the way in which the bumpers are often injured, making the car difficult to couple and causing much loss of time in making up trips.

Referring to the claim of some that iron cars when derailed are much harder to again place them on the tracks than are wooden cars, let me say that my experience with iron cars in low coal is that they can be replaced on the track more easily and quickly than wooden cars of the same capacity. The reason is that there is so much give in a wooden car that one must lift higher before the wheels can be brought over the rails, than when lifting an iron car back on the track.

Wood Cars Require Constant Repairs Owing to the Severe Conditions of Use

The use of an endless chain for hauling trips up a slope is very hard on wooden cars, as is also a direct steam dump when that forms part of the equipment on the tipple. Iron cars stand this hard service much better and are seldom injured, while wooden ones are frequently disabled. At our mine, when employing wooden cars, a man was kept busy all the time doing nothing else but repairing those cars, while the only thing that had to be done to an iron car was to occasionally straighten down a drawbar. An iron car of the same outside dimensions as a wooden one has a greater capacity. About the only wear on a steel car is that due to corrosion, and this is so small as to be negligible.

In closing, let me say that it is the opinion of most men with whom I have talked on this subject that steel cars are rapidly replacing wooden ones, in coal mining practice, and that they are far superior and more economical in the end.

John T. Cox,
Pensacola, Fla. United States Naval Air Station.

Man Power and Longwall Mining

Letter No. 2—It was with the deepest interest, but with some misgiving, that I read the letter of Joseph A. Greaves, *Coal Age*, Sept. 19, p. 564. The manner in which he describes some of the minor difficulties in connection with longwall mining is indeed amusing; but it occurs to me that he has omitted some of the far more weighty and important difficulties in connection with starting longwall work.

Like Mr. Greaves, my experience in longwall mining was obtained in mines in the North of England, where we had no troubles of the kind he has described as being due to the employment of miners of different nationalities. Let me stop long enough, here, to say that there must have been something radically wrong with the haulage arrangement, in the instance mentioned by my friend, when Tony and Mike would fall to fighting over a single empty where 20 carloads of coal were down ready for loading.

Now, I fully agree with Mr. Greaves in the belief that longwall mining has peculiar advantages where the conditions are favorable to its application, but there are a lot of things that must be first considered in order to insure the success of this method. As I have said, Mr. Greaves has seemingly overlooked these important features. However, it may be that the longwell mentioned in his letter was only in its infancy and had not reached a point where real trouble begins.

Success of Longwall Depends on a Right Start

Everything depends on the manner in which longwall work is started. One must be familiar with what is sure to happen if the work is not started right. Study well the conditions. Good judgment must be used in deciding whether it is better to take bottom or top for the packwalls. To make a mistake in this regard will give no end of trouble when the face has advanced a considerable distance and the weight of the overburden rests fairly on the packwalls. It is then that the roof will more than likely show a tendency to cut along the face. To overcome this difficulty, which would mean disaster, it is important to have large and well-built packwalls that will take the weight and throw it back on the solid coal.

My recollection goes back to the time when I was employed in a longwall mine where I gained the first ten years of my mining experience. In that mine, the seam was about 39 in. in thickness, and the packs would be squeezed down to 30 in. some distance back from the face. The packwalls were well built, bottom being lifted to supply the material for that purpose. The gateways were 36 ft. apart, center to center. Not a prop was permitted to stand in the gob, but the packs were built solid from one gateway to another.

The roof of the seam was a slate that could be readily taken down when this was required to make headroom on the roads. I never saw a wood chock set in any gateway, except at the corner of each gate, which is all that is necessary, I believe, provided the packwalls are well built. The work was all pickwork and no explosive was used except to shoot bottom. The work in this mine was entirely successful.

In contrast with the foregoing, I recall working in another mine where it was decided to start longwall,

in a single section of the mine. The conditions there seemed favorable and a pair of entries were driven far enough to start eight gateways. I think these were driven on about 70- or 80-ft. centers and the back entry was used to ventilate the longwall face. Men were set to work to slab both sides of the main heading its entire length. A wood chock was set at the corner of each proposed gateway, and the roof was shot down over the gateroad, the rock being used for packwalls.

This instance of longwall work would compare well, I believe, with that described by Mr. Greaves. "Coal getting" was the chief object for the first few weeks. Then the roof began to break along the face and settled hard on the packs, causing the cars to scrub both the sides and the top. The nightshift could not shoot down the top and build the packwalls fast enough, and it was no uncommon thing to see half the loaders digging bottom on the roads to get the cars into the face. Under these conditions, it will surprise no one to know that very much rock had to be loaded out. Altogether it was a miserable piece of work. I stayed there long enough to know that they had made a mistake in the start.

Let me repeat, then, in closing, start your longwall right and it will be sure to succeed if conditions are favorable. Do not expect to see the coal continue to pour out, as many do, in the first few weeks; but give attention to what is necessary to success in the future when the work is well under way.

McIntyre, Penn. THOMAS HOGARTH.

Hindrances to Coal Production

Letter No. 4—There may be a good deal of truth in the remarks of "Observer," made in his letter, *Coal Age*, Sept. 26, p. 612, where he speaks of men "passing the buck." The expression is seemingly intended to infer that men are prone to shift the responsibility from their own shoulders to those of others who are working under them.

Now, I believe I am in a position to know something of the inside workings of affairs, under conditions similar to those to which he has referred. As far as I am able to observe, the coal operator, today, is not leaving a thing undone that will help to increase the production of coal. Officials are ordered to "get out the coal," and reminded that it is up to coal producers to *win the war*. They are not sparing any reasonable expense, which is a secondary consideration at the present time.

During the past year I have attended meetings of all kinds, having for their object the speeding up of production. We all know that the expense sheet, in many cases has gone clean out of sight; but I have yet to hear a single official blamed on that account. The sole question asked is, "What are you doing to speed up production in your district?" If a machine is needed at the mine it seems only to be a matter of how soon it can be gotten. My observation is that operators, almost without exception, are anxious and willing to try out any system that seems feasible and promises to increase the output of the mine.

Speaking of miners and their loyalty to the cause in which we are all interested at present, only the other day the Pit Committee came to me with a small grievance. It was a trifling matter, and, after listening to their complaints and suggested remedy, I pointed out to them that what they asked would be a detriment to them and to all concerned. I urged them to give their thoughts to what would increase the production of the mine 10 tons a day. I told them that I would gladly act on any suggestion of theirs that had this for its object and would even be willing to pay them for it.

The interview ended with my urging them not to go to their meeting seeking to bring up some little matter that someone was prone to consider a grievance when other and more important matters should be coming before them. Above all, I asked them not to consider that the mine foreman and the superintendent were on one side of the fence and they on the other, but rather to regard all as on the same side and pulling in the same direction to accomplish the same purpose.

Patriotism of Miners Should Lead Them To Overlook Little Troubles

Let me suggest, here, if our miners all possessed the right feeling, there would be no need for the foreman or superintendent to wonder, the morning following a meeting held by the men, whether the miners were going to work or not. While I believe that the vast majority of miners are loyal to our common cause, things frequently occur that cause me to doubt whether many of them realize what true loyalty means, in respect to their attitude in relation to trivial and unimportant matters. I am led to think that ignorance of existing conditions is often the reason why miners allow these little matters to trouble them.

In reading the letter to which I have referred, it appears to me that the writer blames the management of the mine for a few of the miners producing but six, eight or ten tons a day, instead of 16, 18 or 20 tons, as shown by the weigh sheet. While I am not familiar with the mine to which he refers, or its management, I can tell him where 99 per cent. of the trouble lies.

Reflect, for a moment, on the fact that from 20 to 30 men often depend for the coal they can load the following day on what a single machine runner can cut the preceding night. If that man is idle, or meets with difficulties beyond his control, it is clear that the men will have little coal to load the next day. Or, when the machine is cutting the coal on the dayshift, it may happen that several places are cleaned up at the same time, and the men working in some of those places must then wait until the machine can reach them.

Difficulty Arises When Machine Men Lay Off

In a mine where there are 10 or 12 cutters, it is the foreman's biggest job to know if all of these men are in their places. Perhaps, two or three of them have failed to come to work and the foreman must hunt up men to run their machines. He may have to take men who know little how to run a machine and progress is slow.

It may be argued that every mine foreman should have two or three extra cutters available. Even when this is the case it will happen frequently that they are working in places where they can earn more money than by running a machine. Here, again, the foreman cannot be blamed because the men have not the coal to load.

Again, there may be two or three of the machines in need of repair, and the machine boss can only be in one

place at one time, so that here is another cause for delay and loaders must wait for their coal to be cut. In visiting many places where the coal is cut by machine, I have never yet found a mine where there is never any trouble and delay caused by the coal not being cut ready for the miners to load when they come to work. Trouble of this kind will cease when we have machines that do not get out of repair and machine runners that are not prone to lie idle when the notion takes them. We should not be hasty in blaming these troubles on the management, who are often helpless to avoid them.

McIntyre, Penn. THOMAS HOGARTH.

The Miner and His Pleasure

Letter No. 5—I read with much satisfaction and pleasure the letter of Thomas Hogarth, *Coal Age*, Aug. 15, p. 329, regarding the right of the miner to enjoy himself. Like him and others who have expressed the same sentiments, I feel that the miner should have all the pleasure possible, as long as he does not let it interfere with his work in the mine or keep him from doing his whole duty to his country.

Reference has been made to miners owning autos, and the suggestion was offered that this fact might lead many miners to neglect their work in the mine, for the purpose of taking long pleasure trips and visiting their friends in distant places. Let me say that I cannot think of any class of people who are more entitled to own and enjoy an automobile than the miner who works underground, shut out from the light of day, in order to furnish the coal needed in other industries and in the homes.

MINERS' NEED OF RECREATION

No industrial worker makes as great a sacrifice, in this respect, as the coal miner whose hours are spent, day after day, in the dark, damp and dangerous recesses of the mine. I have spent 13 years of my life in the mine, and I know that after a man has worked steadily for months in an atmosphere loaded with powder smoke and poisonous gases, he needs rest and sunshine. He must have recreation in the sunshine in order to build himself up and strengthen him for doing more and better work.

My observation is that miners who own automobiles are generally the very ones that are found most regularly in their working places. Almost without exception, the owner of an automobile is a man who, by hard and steady work, has saved enough money to buy his machine. He is not the man who will allow the pleasure derived from its use to keep him away from his work in the mine.

We all know that it has been a hard task to keep the miner in his place this summer. It is in the summer season that many miners are accustomed to take their hunting and fishing trips and be gone for a week or two at a time. But I have noticed that very little of this has been going on the past summer. A few would go off Saturday night and be gone all day Sunday, but Monday morning would find them back in the mines stronger and better fitted for their week's work.

I have frequently overheard miners remark that they would go fishing and stay a couple of weeks if it were not for the war and the fact that the boys who have gone from them need their help in the mine. Miners recognize that coal is needed to produce the shells and other war munitions required at the front and their conclusion is that, "If the boys can stand it in the trenches, we can stay at our places in the mine." Patriotism runs high among miners, the large majority of whom feel that they must sacrifice everything in order to be able to face the boys when they come home. This fact and the dread of being known as a slacker has worked miracles with the average miner.

Miners, as a class, are hard to understand, and often misjudged by those who are not acquainted with mining conditions. It is true that the miner is prone to be suspicious of everything that will take away his liberty, which he prizes highly. Because he is frequently seen on the street, before the hour for quitting work in the mines has arrived, the remark is often made that he should be at work in the mine, instead of loafing and wasting his time on top when the country is in such great need of coal. If the truth were known, however, the man referred to has completed his day's work and could do no more if he had stayed in his place in the mine. His work below being finished, he has come up to enjoy an hour or more of sunshine that will fit him for work the next day.

A GOOD MINER UNJUSTLY CRITICIZED

An instance of this kind occurred not long since when a traveling man pointed to a large stout young fellow, a miner, who was resting in the shade an hour or so before quitting time. The traveling man remarked, "That fellow should be in the mine loading coal instead of loitering there." On being told that the man had loaded a day's turn and a good one at that, and that he could not have loaded any more coal that day had he remained in his place in the mine, the traveling man showed his ignorance of coal mining by remarking further that he thought every coal miner was supposed to stay in the mine and work eight hours' full time.

Criticism of this kind and articles of a similar nature that appear in the daily press, from time to time, do the hard working miner a great injustice. He is accused of idleness when his day's work is done and he takes his much-needed recreation in the fresh air and sunshine above ground, which alone can fit him for steady work, day in and day out. He is denied a vacation and the right of many enjoyments in life, by an unfeeling public, who know only of the great need of coal and are unfamiliar with its getting. As in the incident I have just mentioned, many who are so willing to criticise the miner for taking a little pleasure might themselves be employed in a more useful business. Many of them might, with a little training, enter the mines themselves and help to get out the coal.

My word, in closing, is that the miner should not only be given all the rest and sunshine possible, but encouraged to take it, in order that he may remain healthy and able to give the country his best service, every day that cars are on the track and his coal is cut ready for him to load. More often it happens that no cars are set in his place or his coal is not cut.

Cleaton, Ky. OSTEL BULLOCK.

INQUIRIES OF GENERAL INTEREST

Locating the Coal Beyond a Fault

Kindly permit me to describe briefly an experience we had recently in one of our mines, hoping that it may lead to a discussion that will not only prove helpful to ourselves but be of interest to others.

In Fig. 1 is shown the general plan of the entries, together with numerous cross-sections taken at the several points indicated on the plan, while Fig. 2 represents roughly a profile or vertical section taken on the line of the main headings. The profile shows two seams opened by drifts. As indicated in the figure the drift in the upper or "X seam" has been driven 2000 ft. where it intersected a fault.

As shown in Fig. 2, the lower or "Y seam" underlies the X seam, from which it is separated by 55 ft. of rock strata. Although practically level, both of these seams have a grade of 4 per cent. in favor of the loaded cars. As indicated in the figure, the drift or main heading in the Y seam is driven less than half the distance reached in the upper seam.

As appears in the general plan, Fig. 1, the main-drift headings in the X seam, are driven three abreast. The middle one, being somewhat in advance of the other

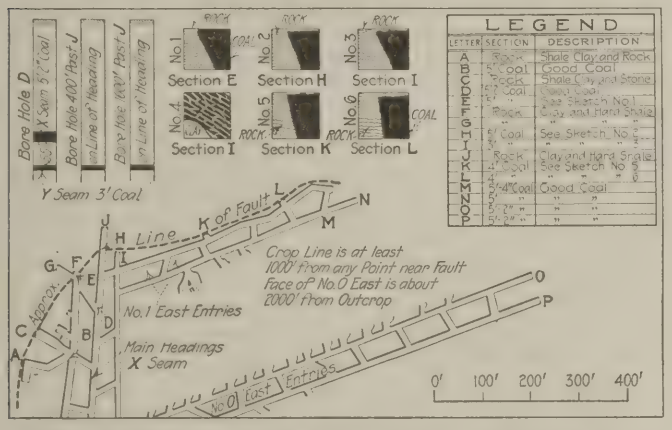

FIG. 1. PLAN OF MINE AND DETAIL OF FAULT AND BOREHOLES

two, was the first to encounter the fault, which was of such peculiar sharpness that work there was stopped until the other two headings reached the fault. It was thought that they would establish the approximate line of the break and show, by the character of the strata beyond, whether the fault was an upthrow or a downthrow and help to ascertain the approximate amount of the displacement. However, when the two side entries struck the fault, the results were so indefinite and unsatisfactory, that it was determined to drive No. 1 *E* heading along the line of fault, and prospect the district by driving holes *K* and *L* directly into the fault.

We were now enabled to obtain cross-sections at the face of each of the three main headings and the holes driven to the fault at *K* and *L*. These cross-sections are shown in detail in the sketches Nos. 1, 2, 3, 4, 5 and 6, Fig. 1. Each of these sections is shown looking toward the right rib and the line of slip between the rock and the coal is clearly indicated in each, except in sketch No. 4 where the section is taken looking directly at the face and shows only rock strata above and a clay vein at the lower left-hand corner close to the rib.

After studying these sections carefully for a time, and being unable to obtain from them the definite information desired, we attempted to locate the coal beyond the fault by driving short boreholes up and down, in the face of each of the main headings. But these holes failing to show the presence of the coal, we next put down two boreholes, one 400 ft. and the other 1600 ft. ahead of the face of the main headings, as indicated on the profile, in Fig. 2. As there shown, the first of

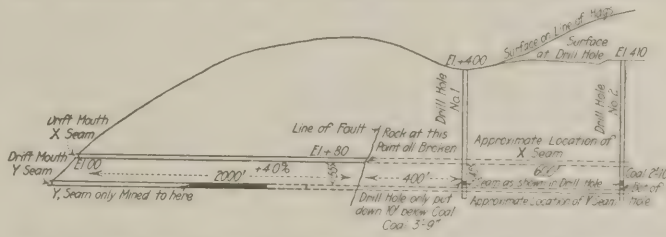

FIG. 2. APPROXIMATE PROFILE ON LINE OF HEADINGS

these boreholes struck coal, 3 ft. 9 in. in thickness, at a depth that was approximately 45 ft. below the level of the X seam. This hole was put down only 10 ft. below that coal and further drilling was stopped.

The second borehole, 1600 ft. ahead of the face of the main headings, struck 2 ft. 10 in. of coal, at approximately the same level as that shown in the first borehole. It was thought, at the time, that these two boreholes had failed to locate the X seam, and that the coal struck was probably the Y seam. The Y seam, however, rarely shows 3 ft. 9 in. of coal, the average thickness of that seam being from 2 ft. 9 in. to 3 ft., in this region. The appearance of the strata at the face of the main heading, in the fault, indicates that the strata had been subjected to a tremendous pressure, as the rock there is much broken.

We are particularly anxious to get from *Coal Age* and its readers their opinions in respect to this fault. If it is not possible to locate the continuation of the X seam, it will mean a large loss to our company.

Johnstown, Penn. SUPERINTENDENT.

From the information furnished by this correspondent, it is the opinion of *Coal Age* that the fault is a downthrow. Our belief is that the coal struck in the two boreholes sunk from the surface is the continuation of the upper or X seam. Had the borings been carried a few feet deeper they would probably have found the Y seam below. Assuming the elevations given to be correct and making due allowance for the 4 per cent. rise in the strata, the indication is that this fault is a downthrow of approximately 45 ft. We hope to receive the opinions of others.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—An anemometer registers 30,000 cu.ft. velocity per hour, in an airway 8 x 5 ft. What is the volume of air passing per minute and how will you ascertain whether the anemometer is in good working order?

Ans.—The question probably intends to say that the anemometer registers a velocity of 30,000 ft. per hour, which would be 30,000 ÷ 60 = 500 ft. per minute. Then, assuming that this is an average velocity for the entire section of the airway, the sectional area being 8 × 5 = 40 sq.ft., the volume of air passing per minute is 40 × 500 = 20,000 cu.ft. per minute.

An anemometer, in constant use, should be returned to the factory once in every one or two years, for the purpose of testing its calibration and determining the accuracy of its readings. A rough method of checking the reading of an anemometer in a mine, however, is the following:

Select a straight piece of entry 100 yd. in length where a good current of air is passing. Starting from the point of observation where the reading of the anemometer is to be taken, measure off this distance in the direction the air is traveling and place a man at that point. Now, expose the anemometer to the air current in the center of the airway, holding the instrument at arm's length so that the flow of air through it will be unobstructed.

With a watch in one hand, let a small flash of powder be touched off at the instrument and note the exact time by the watch when this is done. The powder should be in a position such that its smoke will be borne on the air current in the center of the airway. The observer at the other end of the stretch, 100 yd. distant, signals when he first detects the smoke of the powder at that point, and the time interval is noted by the watch. For the purpose of a check, the second observer also notes the difference in time between the flash of the powder, which he observes, and the time when he first detects the smoke.

The anemometer is now held exposed for the full length of the minute and its reading taken. Assuming the reading shows a velocity of 500 ft. per minute, the interval of time between the flash of powder and the detection of the smoke 300 ft. distant should be $\frac{3}{5} \times 60 = 36$ seconds, which would indicate that the reading of the anemometer is approximately correct. It is needless to say that this observation for determining the correctness of the anemometer reading should be made at a time when the mine is idle and the circulation of the air normally regular.

Ques.—With a fan of 30 hp., from which you are obtaining only 50 per cent. useful effect, while the water gage stands at 2.3 in., what quantity of air per minute should you get?

Ans.—With 50 per cent. useful effect, the horsepower on the air is one-half that developed by the fan, or 15 hp. Ventilating under a 2.3-in. water gage, the quantity of air circulated by 15 hp. is

$$Q = \frac{33{,}000H}{5.2w.g.} = \frac{33.000 \times 15}{5.2 \times 2.3} = 41{,}390 \text{ cu.ft. per min.}$$

Ques.—(a) What is the general efficiency of a fan? (b) If the horsepower of an engine is 40 and the water gage 1.5 in., what quantity of air wil you expect to get?

Ans.—(a) The general efficiency of a mine ventilating fan, including that of the engine driving the same, may be stated as varying from 60 to 80 per cent., depending on numerous conditions.

(b) Assuming in this case the combined efficiency of the fan and engine as, say 60 per cent., the engine developing 40 i.h.p., the power on the air is 0.60 × 40 = 24 hp. The quantity of air circulated by this power against a water gage of 1.5 in. is calculated by the formula

$$Q = \frac{33{,}000H}{5.2w.g.} = \frac{33{,}000 \times 24}{5.2 \times 1.5} = 101.540 \text{ cu.ft. per min.}$$

Ques.—(a) What pressure and power would be required to produce and maintain an air volume of 150,000 cu.ft. per min., through an airway 8 x 10 ft. and 3000 ft. long? (b) What would be the total power exerted by the fan engine if 70 per cent. of the power was expended on the air?

Ans.—(a) First find the sectional area, rubbing surface and velocity of the air as follows:

Sectional area, $a = 8 \times 10 = 80$ sq.ft.;

Rubbing surface, $s = 2(8 + 10)3000 = 108{,}000$ sq.ft.;

Velocity, $v = 150{,}000 \div 80 = 1875$ ft. per min.

The pressure per square foot producing a circulation of 150,000 cu.ft. per min. in this airway is then

$$p = \frac{ksv^2}{a} = \frac{0.00000002 \times 108{,}000 \times 1875^2}{80}$$

$$= \text{say } 95 \text{ lb. per sq.ft.}$$

The power producing the circulation is found by multiplying this unit pressure by the quantity of air in circulation and dividing the product by 33,000; thus,

$$H = \frac{Qp}{33{,}000} = \frac{150{,}000 \times 95}{33{,}000} = 431+ \text{ hp.}$$

(b) Assuming that the power on the air, as just found, is 70 per cent. of the total power exerted by the engine driving the fan, the latter is 431 ÷ 0.70 = 615 + hp.

Ques.—What would be the current required for a motor of 25 hp., at a pressure of 500 volts?

Ans.—Since one horsepower is equivalent to 746 watts and the current (C). in amperes, is aqual to the voltage (W) divided by the pressure or electromotive force (E), in volts, the required current, in this case, is

$$C = \frac{W}{E} = \frac{746H}{E} = \frac{746 \times 25}{500} = 37.3 \text{ amp.}$$

It is assumed in this solution that the motor is developing its full rating of power.

COAL AND COKE NEWS

Harrisburg, Penn.

In an opinion handed down by presiding Judge Kunkel, on Oct. 16, the intimation is made that a treaty between the United States and Italy may invalidate the Workmen's Compensation Act of this state. There is a provision in the act that non-resident aliens cannot collect compensation under the state law, and the contention has been raised that under the treaty relations with Italy, Italian subjects have the same rights in the courts of this nation as American citizens. If this contention is correct, the Judge stated that the provision in the act cannot stand. By ruling that the Dauphin County court had no jurisdiction in the case, the judge was not required to decide the question of the validity of the act.

The facts in the case in which this interesting question arose are as follows: The parents of Giuseppi Liberator reside in Italy, and he was killed in this state. The parents brought suit for compensation through their representative in this country, and sought damages. No claim for compensation was made to the Compensation Board because of the provision in the act, and when it came before the Judge, he ruled that the court had lack of jurisdiction.

The time limit for presenting the claim to the Compensation Board has now expired, and it is too late to take action before it. If the case had been heard by it, and appealed to the court, the question of the validity of the act would have been decided.

Whether the State of Pennsylvania goes dry and remains so until the end of the war, as a war measure, is up to the wholesale liquor dealers of the state. Unless they cease to supply "speak-easies" in the coal regions, the United States Government will declare Pennsylvania a military zone and shut out all liquors, particularly in the soft-coal fields. None of the licensed wholesale and retail dealers now closed by order of the State Board of Health to prevent the spread of influenza will be permitted to reopen, and this state will join the list of permanently dry ones.

The decrease of production due to the influenza has become serious. In the Central Pennsylvania district it amounted to 250,000 tons the last two weeks. Coupled with this is the loss due to drunkenness. There are more than 1200 mines in this district. If only one man at each mine were idle it would mean 1200 tons daily and a loss in tonnage of 6000 tons a day. The average of idleness due to liquor is considerably greater than this. The loss of production in the anthracite region due to the influenza is estimated at about 25,000 to 35,000 tons daily.

Uniontown, Penn.

That liquor is a serious hindrance to the production of an increased tonnage of coal is conclusively proved in the weekly report of Manager of Production W. L. Byers for the week ended Oct. 12. During that period the imposition of health orders due to the Spanish influenza epidemic closed every saloon, distillery and brewery in the region and provided the first opportunity in history to put to the test the operators' contention that the unlimited distribution of liquor reacted against the man-power efficiency of the region.

Another new high record for the Connellsville region was established during the week, the output of 749,384 tons in terms of coal topping the previous high record for the week ended Sept. 18 by 4541 tons. The gain of 31,547 tons as compared with the production for the week ended Oct. 5 is credited almost entirely by fuel administration officials to the declaration of the "dry zone" by the state health order.

The battle between opposing financial interests for the control of the Thompson Connellsville Coke Co., one of the "war brides" of the Connellsville coke region, will be settled in open court under the supervision of Judge J. Q. Van Swearingen, presiding judge. Judge Van Swearingen on Saturday, Oct. 19 filed an opinion and order in which he directed that the annual meeting of the stockholders for the purpose of electing officers and directors be held in open court. The annual stockholders' meeting was originally scheduled for May 6 last but was restrained by an injunction when the present controversy developed.

Balance of voting power to control the election seems to rest in a block of 2500 shares of stock, involved in the J. V. Thompson tangle, which was placed as collateral to secure his indebtedness with a Pittsburgh banking institution. J. H. Hillman, Jr., a prominent Pittsburgh operator and coal broker, who has recently acquired extensive interests in the Fayette County region, purchased the block of stock a few days before the scheduled meeting of the stockholders but was denied the right of transferring it to his name for the reason that the stock transfer books had then been closed until after the election. Harvey R. Worthington and others then petitioned the Fayette County courts for an injunction, and at the hearing Mr. Hillman entered into the controversy as one of the plaintiffs.

In the decision just filed Judge Van Swearingen finds from the evidence offered that unless the court exercises its powers to supervise and control the corporate election for directors there is real danger that the meeting of the stockholders will be subject to confusion, disturbance and disorder, and that the election will not be fairly, impartially and legally conducted.

The trouble began when the majority of the present board of directors desired to make distribution of large sums of money as dividends to the stockholders, while the other directors insisted on first paying the company's indebtedness. The company has a capital stock of $3,000,000. It owns large coal properties in Fayette County and conducts extensive mining operations. John P. Brennen is president of the company and W. G. Rock is secretary and assistant treasurer. Other members of the present board of directors are John M. Reyburn, A. S. Livengood, J. V. Thompson, Edward R. Jenkins and Andrew A. Thompson. The court did not name a date for the stockholders' meeting.

Charleston, W. Va.

Operations in the Fairmont district are still wrestling with late placements and a very meager car supply. For instance, on Oct. 12 there were only 798 cars in the region and only 503 were placed by 7 o'clock. The day before, despite the fact that only 500 cars were placed by 7:00 a. m., 1095 cars were loaded. Car service in the Fairmont region has been about as poor as it could be for the last two months or more, and the production loss has consequently been very large through no fault of the operators or miners.

Decreases in production have followed in the wake of sickness in the Kanawha district, although the tonnage produced even under such a handicap is greater than it was at any time during September. As if a labor shortage were not enough, for the last three days of last week there was an acute car shortage, attributed by the Chesapeake & Ohio to the fact that so many engines were in shop. Tonnage figures for the week ended Oct. 12 show 171,096 tons of coal produced, this being a reduction in the output of 33,000 tons. It is easy to put one's finger on the trouble as the total number of hours worked was only 5228, hours lost from labor shortage being 556 and from car shortage 1155. Spanish influenza was on the rampage in certain parts of the district.

Through causes over which neither miners nor operators have any control it is doubtful if the mines of the Tug River and Pocahontas districts are able to reach the two-million ton production goal set for October, although a herculean effort is being made to achieve such a result. Up until the 12th shipments of coal had aggregated 14,129 cars. Taking into consideration the reduced man power in the district and the prevalence of Spanish influenza, the record so far is considered very good. There are 1800 cases of influenza in the two fields and 2600 cases among railroad employees. An increase under such conditions indicates how hard the men are working to reach the quota fixed by the Federal Fuel Administration.

With Spanish influenza spreading very rapidly in both the Tug River and Pocahontas districts, the output of 462,757 tons, for the week ended Oct. 12, even though a decrease of 6975 tons as compared with the previous week, is considered very good. The epidemic has not only affected the mining industry but also the railroads.

The total production in the New River and Winding Gulf fields the week ended Oct. 12 was 298,887 tons, which was an increase of 14,300 tons over the preceding week, the preceding week, however, having shown a decrease over the week previous. The increase was accomplished despite many obstacles. At least 1000 tons was lost at one mine through a wreck. Another wreck in the New River field curtailed production by at least 1500 tons. It is estimated that influenza in the mining districts is causing at least a 10 per cent. loss in production in the New River and Winding Gulf field. The same disease has also affected the railroads, the movements of trains being seriously interfered with.

Birmingham, Ala.

Mining operations in this district are not being affected to any appreciable degree by the wave of influenza which is sweeping the country, despite alarming reports to the contrary. This statement is borne out by the coal production figures for the week of Oct. 5, which have just been released by the Federal Fuel Administration bureau, showing a production of 409,022 tons of coal mined during the week. This is a substantial increase compared to the figures of the week previous, when an output of 383,067 tons was recorded. For the week ending Oct. 12 unofficial estimates show a further increase in output.

Beginning of a limited service by the Federal Railroad Administration of the Warrior River Barge line is affording opportunity for the movement of bunker coal from mines along the river which have no other means of getting their product to the markets. The Payne's Bend mines of the DeBardeleben Co. are now shipping upward of 200 tons of coal per day via barges, while the Franklin Coal Co., on the Locust Fork branch of the river, is shipping coal that was accumulated before the river transportation system was inaugurated. Full service on the river is to be started within another three weeks.

Transportation companies in the district are working hard to keep pace with the demand for service being made by consumers, and as a result car service in the coal section is somewhat improved, though there is still some room for complaint.

PENNSYLVANIA

Anthracite

Shenandoah — The main office of the Thomas Colliery Co., operated by the Madeira Hill Coal Co., of Philadelphia, was destroyed by fire on Oct. 9, together with records, important maps and valuable papers. The fire was caused by crossed electric wires. The breaker was saved by the heroic work of firemen.

Carbondale—Purchased at sale in bankruptcy on Aug. 22, 1917, for $40,000, the property of the West Mountain Coal Co., comprising in all 684 acres on the surface, and including large quantities of mine equipment, dwelling houses, barns, etc., and two large culm banks, holding thousands of tons of coal, has been sold to Max B. Smith and James V. Pinazzi, of Brooklyn, N. Y., for $93,000.

Minersville—The influenza epidemic situation here is appalling. Application was made to the state authorities for martial law, and it is expected the town will soon be under full control of the State Police. The local authorities say the situation is entirely beyond them. Corpses are being found which have been lying in houses for several days without attention, and sick and dead are being found together. It is expected to completely isolate the town. Graves cannot be dug fast enough on account of the scarcity of labor, and friends and members of families are being called upon to perform this work.

The Buck Run colliery, on which the town depends for support, has been compelled to close down.

Bituminous

Uniontown—As the result of a personal request from Fuel Administrator Garfield about 95 per cent. of the miners and the men employed at the coke plants worked on Liberty Day.

Greensboro—The Greensboro Coal Co. has received a permit to construct a coal tipple on the left bank of the Monongahela River at this place, about 2½ miles above lock No. 7.

Savan—The tipple at the new operation of Lowther & Davis, of Indiana, was put into commission this week. The mine is opened on the Hamilton tract in the Upper Freeport vein. The capacity is about 100 tons per day at the present time.

Blairsville—The Davis Coal Co. has opened a new mine on the Campbell farm near Smith Station to secure a block of coal which could not be reached from the old mine. The new mine has a production of about one car per day at the present time.

Pittsburgh—The tract of coal known as the Murray holdings and owned by Leander G. Edward, and Bertram G. Murray, comprising 155 acres in Frazier Township, has been sold to the Crucible Fuel Co. of Pittsburgh, a subsidiary of the Crucible Steel Company of America. The consideration was not mentioned.

Greensburg—Believing that a long "dry spell" is to be established, Italians and Austrians, particularly, are purchasing grapes in carloads in the mining sections in this county for conversion into wine. Reports from the "moonshine" sections in the Laurel Hill Mountains indicate a revival in the "mountain dew" business.

Brookville—Application will be made for a charter for a coal company to be known as the Sunday Hollow Coal Co., by Ira J. Campbell, Joseph B. Henderson and John E. Geist. Several hundred acres of coal have been purchased near Putneyville, in Armstrong County. The vein has been tested by drilling and the coal is said to be of a good thickness and fine quality. A switch will be put in, tipple erected, and the mine made modern in every respect. It is doubtful if the mine will be ready to produce coal this year.

Altoona—The Russett Coal Co., which supplies a large portion of the commercial and domestic coal used in Altoona, has started to electrify its mine and is installing electric shortwall machines. A new drift has been started and a tramroad proposed from this drift to the Buckhorn road. This will place the operation about four miles from the city on a downgrade haul. It will relieve the fuel shortage in Altoona, as the new operation will have a capacity of 500 tons daily. No railroad shipments will be made from this mine, all being hauled to the city in trucks.

WEST VIRGINIA

Dana—The shipment of coal from the plant of the Dana Coal Co., on Campbell's Creek, was begun last week. The plant was only recently completed. H. A. Jepson of Marting, will act as general manager.

Acme—In order to protect its Acme mine against any damage from floods, the Cabin Creek Consolidated Coal Co. of which Josiah Keely is general manager, is having a mile of rip rap work put in.

Charleston—A lease from Queen Land Co. conveying a tract of 1004 acres of Big Sandy district coal land to Kanely Coal Co., has been filed for record in the county clerk's office. The lease runs 20 years at a royalty of 10c. a ton.

Charleston—By Jan. 1 the Burch Fork Coal Co. expects to have its plant on Marsh Fork, in the Kanawha district, in operation. Construction work is being pushed under the direction of L. C. Lilly, the general manager of the company.

Ohley—A number of improvements have been made at the plant of the Coal Fork Coal Co. at Ohley on Cabin Creek, including the installation of a new motor and mining machine, the company also having put up a substation. The superintendent at this plant is S. W. Smith.

Clendenin—After several months' construction work, the new plant of the McBower Coal Co. at Clendenin, on the Coal & Coke, is almost ready for operation and it is probable that the shipment of coal will be begun in a few days. The general manager of the company is Max Goldman of Clendenin.

Laing—New equipment being added to the Berlin plant of the Wyatt Coal Co. at Laing, on Cabin Creek, includes an electric hoist, the company being engaged in making such improvements as may be necessary, under the supervision of James Martin, superintendent, to increase the company's output.

Fairmont—An agreement has been entered into between the United States Government and the Domestic Coal Corporation, recently chartered under the laws of Delaware, under the terms of which the Government will build the plant, now in course of construction at the old Fair Grounds here, but the corporation will operate the plant.

Fairmont—Spanish influenza has cut into the coal production considerably. The disease is prevalent everywhere in West Virginia and no coal fields have escaped. The Fairmont fields lost 20 per cent. in production the first two weeks of October, owing not so much to the disease in the mines, though the disease has since obtained a foothold, but to the interference with railroading. The Norfolk & Western fields, where the car supply has not been a source of worry, could not escape the epidemic and many mines are practically closed. The Chesapeake & Ohio field, which has had a good car supply recently, is crippled both as to railroad men and miners. The Big Sandy and Elkhorn districts of Kentucky, which adjoin one corner of West Virginia, suffers to such an extent that the output has been reduced 50 per cent. There are 1917 cases at Jenkins, Ky., where the Consolidated Coal Co. has one of the largest operations in the Big Sandy field.

Moundsville—An ineffectual effort was made the night of Oct. 11 to burn the tipple of the Panama Coal Co., near here, waste saturated with oil being found at the base of the tipple by members of the night crew who were leaving the mine when Night Watchman Hendricks gave the alarm.

INDIANA

Sullivan—Clyde Philips, a miner at Glendora, fell from the top of the mine tipple to the bottom of the sump, a distance of 125 feet, and escaped with only a fractured knee and a broken collar bone. He was doing repair work in the tipple when the bucket was drawn up from the shaft, knocking him from his position.

Oglesby—Members of Oglesby local union No. 929 have drafted resolutions asking for the opening of the mine of the Oglesby Coal Co., which was closed by a permanent injunction brought about by litigation of the Marquette Cement Manufacturing Co. The mine workers represented that many of them owned their homes in Oglesby and that they wished to remain there. It was also pointed out that the operation of the mine at this time would help the country.

ILLINOIS

Orient—The Orient No. 1 mine of the Chicago, Wilmington and Franklin Coal Co. hoisted, prepared and loaded for shipment during the week ended Oct. 12 a total of 32,514 tons of coal. The average output—5419 tons—was larger than any single day's output of any other mine in the southern Illinois field. On Oct. 10, with 738 men reporting for work, the mine hoisted 6008 tons, which is believed to be the largest single day's output ever reported.

Duquoin—Duquoin is to have a $200,000 hospital as the gift of Mrs. Lillie F. Browning who died recently while on a visit to Oklahoma City, Okla. In her will, which has been filed, she makes a bequest for that purpose and further directs that a trust fund of $40,000 is to ultimately go to the hospital. The institution will be named the Marshall Browning Hospital, in memory of her husband, who was president of the St. Louis & O'Fallon Coal Co., the St. Louis & O'Fallon Railroad Co. and the Western Anthracite Coal and Coke Co. He died in 1908.

Bethalto—The Bethalto Coal and Mining Co. has been organized to take over the right to the Spencer mine on the Munsull place near here, the shaft of which has been filled with water for twenty years. When the shaft was sunk by John Spencer so much water was found that under the conditions then prevailing the mine could not be profitably operated. But it is different now. The new company, headed by George Prescott, has pumped out the shaft, made repairs and put the mine in operation. There is a 6-ft. vein under a rock top at a depth of 70 ft. The rights cover 175 acres.

Staunton—Five robbers held up the office force of the Mt. Olive and Staunton Coal Co., near here, Tuesday afternoon, Oct. 15, and escaped with $13,300 payroll money. The robbers drove up to the office in an automobile and while one stayed in the machine and another acted as lookout, the other three entered and with drawn revolvers drove three clerks, Otto Awe, Robert Barr and Frank Ballwek, into a vault. H. O. Panhorst, auditor and cashier of the company, was then bound to a chair with baling wire and two other men in the office, Charles Miller and Peter Schultz, were lined up against the wall. The robbers gathered the money from Panhorst's desk and drove away in the direction of St. Louis. When an attempt was made to use the telephone to give the alarm the wires were found to have been cut. The company has offered a reward of $500 for the capture of the robbers.

KENTUCKY

Drakesboro—The Black Diamond Mining Co. is installing a ten-ton ice plant for the use of its camp in taking care of foods, and furnishing ice.

Lebanon—Falling slate in the mine of the Willisburg Coal Co., near Harlan, Ky., resulted in the death of Charles Mills, a miner, while 15 men had narrow escapes. The level was choked with a mass of slate.

Mannington, Ky.—The Memphis Coal Mining Co. is arranging to commence work at an early date on the development of extensive additional property, to increase its present capacity. It is said that plans are being prepared for the construction of two new tipples, to be electrically operated, and ground has been broken for the erection of a new power plant for operation.

Henderson—The small but excellent mining property of the Zion Mining Co. has passed from the hands of Herman Mitchell and Chiel Moss to Murray Hughes, Oscar Abbott and Charles Hare. Hale and Hughes for several years have been with the Audubon Mining Co., Hale being mine foreman and Hughes an office man. Abbott is a prominent young farmer and head of the automobile firm of Abbott & Gerard.

TENNESSEE

Kingston—The Emory Gap Coal Mining Co., which recently filed articles of incorporation with a capital of $50,000, is planning for the immediate development of about 600 acres of coal properties in the Harriman section, to have a capacity of 100 tons daily. The company has arranged for the purchase of the necessary mining equipment, and will commence the installation at once. John W. Staples is president.

OKLAHOMA

Ada—Oklahoma is falling behind in its quota of increased coal production. About 94,000 tons more each month are being mined than last year, but the Federal Fuel Administration want 100,000 tons more each month.

COLORADO

Boulder—The Black Diamond Coal Mining Co., which is owned by Boulder capital is planning the erection of a new tipple and the installation of additional mining equipment with the view of increasing its daily capacity to 200 tons. Twenty men are employed at the mine under the management of George Williams. The coal is being hauled from the mine direct to the bins of the consumers by means of motor trucks with capacities ranging from 2 to 5 tons. Analysis of the coal indicates a fuel value of 12,000 B.t.u. W. E. Binder is president of the company.

MONTANA

Great Falls—Arrangements for the development of a new coal mine in the Belt district have been made by a company in which State Senator J. M. Burlingame and other local and Belt men are interested.

ALASKA

Cordova—It is reported that the mine of the Alaska Petroleum and Coal Co. in the Bering field is ready to ship coal for sale, as the Alaska Anthracite Ry. has completed the railway from the mine to Goose City, on Bering River. At Goose Bay the coal will be loaded on scows and taken to the steamship for shipment to Seattle. At the mine 50 men are working three shifts, and already a large quantity of coal has been sacked ready for immediate transportation. The coal is an anthracite and is said to be of superior quality.

Foreign News

The Hague, Netherlands—Announcement was made at the American Legation on Oct. 18 that the United States had offered to place at the immediate disposal of the Dutch Government 100,000 tons of coal monthly for the next twelve months or until the end of the war, on condition that Holland stop sending food to Germany. The coal is to be shipped in vessels sent from Holland.

Lens, France—It will be from 18 months to two years before it will become possible to take out any coal from the mines in the Lens region, which the Germans damaged to the best of their ability before they retired from the city. It is estimated that it will take five years to restore the normal production of the pits. At Courrieres, northeast of Lens, the Germans had blown up the mines before retiring.

Sydney, N. S.—The first battery of the new coke ovens of the Dominion Steel Corporation, comprising 30 ovens, has been completed and put in operation. The second battery of 30 ovens will be ready by the end of the year. When in full operation the output will exceed 1300 tons and the corporation will benefit materially through the saving of operating costs, as the new ovens can be operated by 200 fewer men than the old ones.

Amsterdam, Holland—The immense coal and iron and smelting works owned by Baron de Wendel in Lorraine have been sold to a German syndicate for the normal equivalent of $65,000,000 on the ground they were chiefly owned by French citizens. The process by which this great property was transferred from French to German ownership is called "compulsory liquidation." These fields have long excited the cupidity of German capitalists. The potential ore supply in this field alone has been estimated at $1,900,000,000.

The Hague, Netherlands—The "Neue Freie Presse" reports that the coal problem in Austria-Hungary has become serious on account of the great reduction in output of the mines. It is stated that conditions may not be expected to improve very much and that every possible saving must be effected in order to avoid a coal famine. It is urged that various industrial concerns should combine their operations so that they would consume less coal. During the first quarter of 1918 Austria's coal production was 275,000 tons less than in the corresponding quarter of 1917.

Personals

Baird Haberstadt, well known mining engineer and geologist of Pottsville, Penn., was married on Oct. 15 to Ida Ray Smith. *Coal Age* extends its congratulations.

Robert D. Reeder, superintendent of the Kennon Coal and Mining Co., Flushing, Ohio, has accepted the position of superintendent of the Stotesbury mine of the E. E. White Coal Co., to take effect Nov. 1.

H. C. Owen, of Fairmont, W. Va., has been elected secretary of the Coal Jobbers' Association of the Pittsburgh district, with headquarters in Pittsburgh. The association starts with a membership of about 50 jobbers.

Samuel J. Wilton, of Rockville, Ind., has been appointed assistant mining inspector to succeed **Thomas McNair**, of Clinton, Ind. The duties of the assistant are in the mine fields and include inspection of mines and machinery.

E. J. Best, former chief engineer of the Tennessee Coal, Iron and Railroad Co., and later associated with the Angema Steel Co., of Sault Ste. Marie, has accepted a similar position with the Woodward Iron Co., Woodward, Ala.

Harry Urban, formerly superintendent of the Fairfield byproduct plant of the Tennessee Coal, Iron and Railroad Company, Birmingham, Ala., has been appointed general manager of the Woodward Iron Co., Woodward, Ala.

John T. Darrah, a prominent designing and contracting engineer, connected with the McCrossin Engineering Co., died Oct. 13 at his residence in Birmingham, Ala., after a short illness from Spanish influenza. Mr. Darrah was 39 years of age.

John M. Roan, commissioner of the Ohio Compensation and Statistical Bureau, and recently named inspector for the Federal Fuel Administration for the entire United States, is recovering slowly from a serious automobile accident which occurred recently. While riding along near Wellston, Ohio, he went over an 80-ft. embankment and was rendered unconscious. He was found about three hours later by school children. Several ribs were broken.

Erskine Ramsay, for the past several years first vice-president and chief engineer of the Pratt Consolidated Coal Co. of Birmingham, Ala., has been appointed chief of conservation of the state by the Federal Fuel Administration. Mr. Ramsay has been identified with the mining interests of the Birmingham district for almost 30 years, and many of the improved methods of mining and handling coal are due to his skill and initiative. Mr. Ramsay has established his office at 848 Brown-Marx Building. Associated with Mr. Ramsay is **H. M. Gassman**, who from 1908 to 1916 was chief electrical engineer for the Tennessee Coal, Iron and Railroad Company.

Obituary

Walter S. Wells, president of half a dozen large coal mining companies of Eastern Kentucky, died on Oct. 16 at his home near Prestonburg, Ky., death being due to influenza.

Stewart Buck, paymaster for the Coal Run Mining Co. at Indiana, Penn., died on Oct. 11 after an illness of about one week. He contracted the Spanish influenza while paying the miners at Coal Run and this, together with pneumonia complications, caused his death. He is survived by his widow and one child.

Trade Catalogs

Maintaining Morale. Armstrong Cork Co., Pittsburgh, Penn. Folder. Points out the value of a proper drinking water installation if the workers are to be kept in good health. Without good health high morale and maximum production are impossible.

C-H Standard Attaching Devices. The Cutler-Hammer Mfg. Co., Milwaukee, Wis. Folder. Illustrates 21 of the various attaching devices manufactured by this company. Emphasis is placed on the fact that the C-H "Standard" attaching cap fits all C-H "Standard" plugs and receptacles,, as well as those made by five other leading manufacturers.

Jeffrey Belt Conveyors. Jeffrey Manufacturing Co., Columbus, Ohio. Catalog No. 175. Pp. 80, 6 x 9 in., illustrated. This new catalog of the Jeffrey company can rightfully lay claim to being a complete textbook upon the belt conveyor. Although compiled essentially for the purpose of promoting the use of the Jeffrey Conveyor, the purchaser's requirements for information have been covered in detail.

Industrial News

Chicago, Ill.—The Chicago Pneumatic Tool Co. announces the election of H. D. Megary to the office of secretary, vice W. B. Seelig, resigned.

Charleston, W. Va.—The Snuffer Coal Co., of which John Laing is president, at a recent meeting of its stockholders decided to discontinue business and surrender its charter.

Charleston, W. Va.—The Cabin Creek Consolidated Coal Company has announced the appointment of the following superintendents: Jno. Richard, at the Red Warrier mines: L. G. McCarty, for its United Mines at Wevaco; James Cole at Decota; J. M. Echols at the Quarrier mine.

Cincinnati, Ohio—A fleet of barges containing approximately 45,000 tons of coal arrived in this city recently from the Kanawha field. This is probably the last fleet to arrive in the city as a result of artificial floods caused by operating the various Government dams in the Ohio River. Approximately 250,000 tons of coal has reached Cincinnati as the result of artificial waves.

Duluth, Minn.—Receipts of coal at Duluth and Superior docks during September aggregated 222,015 tons of anthracite and 1,717,588 tons of bituminous, comparing with 315,126 tons of the former and 1,795,640 tons of the latter in the similar month last year. The falling off in receipts for the month is attributed to light stocks at the Lake Erie docks and congestion in railroad lines at that end.

New Albany, Ind.—The Ohio and Indiana Collieries Co., and Edward J. Hackett, of New Albany, were made defendants in two suits for damages of $10,000 each. The Central Indiana Lighting Co., at Columbus, Ind., in bringing the suit claims failure of the companies to supply coal on a contract made on July 25, 1916. Failure to supply plants at Fowler, Bedford and Salem is claimed by the Inter-State Public Service Co. in the other suit.

Columbus, Ohio—The Southern Ohio Coal Exchange announces production figures for the four weeks ending Sept. 28, showing that the output in the southern Ohio field was extra large. The figures do not include railroad fuel used by the lines on which the mines are located. The reports show that during the week ending Sept. 7, the production was 238,531 tons; week ending Sept. 14, 311,925 tons; week ending Sept. 21, 325,737 tons, and for the week ending Sept. 28, 298,358 tons, making a total of 1,174,551 tons for the four weeks.

Toledo, Ohio—The movement of coal from the Toledo docks to the Northwest is continuing satisfactorily, as is shown by the report of the loadings at the docks of the various railroads for the week ending Oct. 12. During the week the Hocking Valley docks handled 206,508 tons as compared with 188,467 tons the previous week, making a total of 4,082,653 tons for the season. During the same week the Toledo & Ohio Central Docks handled 91,000 tons as compared with 92,000 tons the previous week, making a total of 1,790,000 tons since the opening of navigation.

Washington, D. C.—The Draeger Oxygen Apparatus Co. of Wilkinsburg, Penn., has applied to the Federal Trade Commission for license to use eight patents for respiratory, resuscitating and breathing apparatus devices and the trade mark "Pulmotor," which they claim are enemy-owned or controlled. The patents were issued originally to Johann Heinrich Dräger, of Lubeck, Germany, and to the other assigners to the firm of Drägerwerk Heinr. and Bernh. Dräger, of Lubeck, Germany. The commission is considering the merits of the application.

New York, N. Y.—The Anthracite Committee has stopped the practice of certain producers of forcing steam sizes upon the domestic market by issuing the following order: "The committee is informed that certain producers and distributors are forcing steam sizes of coal upon buyers who are entitled to domestic sizes only. This practice the committee cannot under any circumstances permit, and all producers and distributors will be held responsible by the Federal Fuel Administration for either beginning or continuing these methods of moving steam sizes."

New York, N. Y.—Delos W. Cooke, state fuel administrator has announced the appointment of Wilson S. Kinnear as personal representative of the Fuel Administration in coöperation with the Anthracite Committee. Mr. Kinnear is head of the consulting engineer firm of W. S. Kinnear & Co., and was formerly president of the United States Realty Improvement Co. Previous to coming to New York, Mr. Kinnear was president of the Kansas City Terminal Co., and while chief engineer of the Michigan Central Railroad Co. he had charge of the construction of the railroad tunnel under the Detroit River.

Bowerstown, Ohio—Among the mines recently equipped with automatic cages made by the Mining Safety and Device Co., of Bowerstown, Ohio, are Old Ben Coal Corporation's No. 15, Carlinville, Ill.; Republic Collieries Co., Clinton, Ind.; Standard Oil Co.'s No. 4, Carlinville, Ill.; Republic Collieries Co., Russellton, Penn.; Delaware, Lackawanna & Western Railroad Co.'s Pettebone mine, Luzerne, Penn.; Bell & Zoller Mining Co.'s No. 2, Zeigler, Ill.; Lehigh Valley Coal Co.'s Blackwood Colliery, Blackwood, Penn.; Prairie Coal Co., East St. Louis, Ill.; Taylor Mining Co.'s No. 5, Herrin, Ill., and the Lehigh Valley Coal Co.'s Drifton Colliery, Drifton, Penn.

St. Louis, Mo.—Under a ruling of the Fuel Administration, the M. W. Warren Coke Co. will have to refund about $20,000 to purchasers of coal since July 8. Prior to that the basic price for coke was set by the Fuel Administration at $6 to $6.50 per ton, the retail price to be fixed by adding the lowest freight rate from the coke ovens nearest to St. Louis. The ovens at Connellsville, Penn., were then thought to be nearest. The freight rate was $3.60. But attention has been called to the fact that there are ovens at Earlington, Ky., with a freight rate of $1.70. The refund which the company is required to make is the difference between the two freight rates.

Cincinnati, Ohio—In the Federal antitrust suit against the so-called "soft-coal trust," which has been pending in the United States Courts here for several years, a petition has been filed by the Central Union Trust Co. of New York as trustee of $2,294,000 of bonds of the Kanawha & Hocking Coal and Coke Co. asking the court for further instructions in connection with these bonds. The mortgage securing the bonds, it is alleged, provides that certain interest payments may be made after notice of default, and the company desires to know whether the mortgage shall be foreclosed, in spite of the fact that some of the defaulted interest has been paid, or whether efforts shall be made from time to time to collect interest coupons as they fall due. Hearing on this petition before the circuit judges will be set for a later date.

MARKET DEPARTMENT

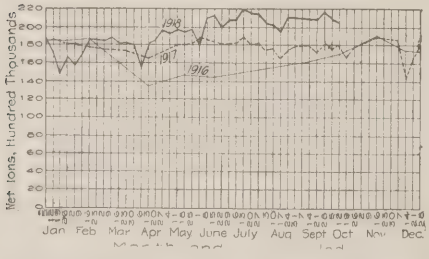
Weekly Review

Peace Talk and Influenza Have Demoralizing Effect on Coal Production—Situation Not So Gloomy as Last Year—Soft Coal Output Keeps Up Well, Though Anthracite Continues to Present a Problem—Some Rumors of Contracts Being Offered

AND now peace talk and influenza have come to trouble the coal-mining industry. Premature reports of the surrender of Germany, printed by misguided and overzealous newspapers, led mine workers in many sections of the country to throw down their tools and enter into an orgy of celebration, with a consequent reduction in the coal output. More serious, however, is the havoc being wrought by the influenza epidemic. In the anthracite region production is being curtailed by the disease, and colliery after colliery has been forced to suspend due to lack of man-power. In the bituminous regions, particularly in central Pennsylvania, the epidemic has begun to make itself felt, and it is feared coal production will be completely demoralized unless success attends the endeavors of health officials and mine operators to eradicate the disease.

Having presented the dark side of the coal situation, justice demands the enumeration of more favorable factors. First and foremost is the belief that there will be no serious shortage of bituminous coal this winter. The needs of essential industries are being supplied as they become evident, and even nonessential industries are permitted to accumulate reserve stocks under a new order issued by the Fuel Administration. New England, which last winter was on the ragged edge of supply, furnishes no cause for anxiety this year, as all the New England ports, those on Long Island Sound as well as east of Cape Cod, have ample stocks of soft coal on hand.

Then, again, the production of soft coal keeps well ahead of last year. For the week ended Oct. 12, the output of bituminous coal is estimated at 12,321,000 net tons, a decrease of 273,000 net tons compared with the week preceding, but 1,317,000 net tons greater than the output of the corresponding wee in 1917. Soft coal production for the first nine months of the calendar year of 1918 is estimated at 447,905,672 net tons, an increase over the same period of last year of 36,179,783 net tons.



Anthracite coal still continues to present a problem, though the authorities are hopeful that all consumers entitled to this grade of coal will receive a supply before long. Though domestic demand continues heavy, the prevalence of warm weather has kept consumption down, and it is believed that household bins are unprecedentedly well stocked with coal. Production of hard coal, unfortunately, continues to decline. For the week ended Oct. 12, the output is estimated at 1,955,000 net tons, a decrease of 97,000 net tons compared with the week of Oct. 5. The total production of anthracite for the coal year to date amounts to 55,658,000 net tons, compared with 54,683,000 tons for 1917.

As for trade conditions, the stove and chestnut sizes of anthracite continue to be in the greatest demand, while the smaller steam sizes drag. Whatever rice and culm moves does so slowly, there being no active call for these two grades. A sign that the bituminous market is easy is evidenced by the fact that contracts are already being offered for next year, but on a twelve-month basis from Oct. 1. With rumors of the war coming to a speedy end, however, buyers are reluctant to commit themselves for a whole year to a contract based on Government prices.

WEEKLY COAL PRODUCTION

The production of bituminous coal during the week ended Oct. 12 is estimated at 12,321,000 net tons, a decrease compared with the week preceding of 273,000 net tons or 2.2 per cent., but an increase over the corresponding week of last year of 1,317,000 net tons or 12 per cent. The average production per working day during the current week is estimated at 2,053,000 net tons as compared with 2,099,000 net tons during the week of Oct. 5, and 1,834,000 net tons during the week of Oct. 12, 1917.

Bituminous coal production during the month of September, 1918, is estimated at

51,687,031 net tons, and exceeds production during the same month of 1917 by 6,579,073 net tons or 14.6 per cent. September production, limited, first by loss of time on Labor Day, second loss of time on Registration Day, and third, by the short month, was approximately 4,000,000 net tons less than production during either July or August and fell slightly below the production of June but exceeded all records prior to June, 1918.

For the first six months of the coal year 1918, production of bituminous coal is estimated at 312,282,414 net tons as against 274,537,172 net tons during the same period of 1917, an increase of 37,745,242 net tons or 13.7 per cent. The requirements during these first six months of coal year 1918, however, exceeded the production during these months of last year by 49,448,828 net tons, so that even with the large increase, production during the first half year fell 11,703,586 net tons or 3.7 per cent. behind the estimated requirements.

Production for the first nine months of the calendar year of 1918 is estimated at 447,905,672 net tons, an increase over the same nine months of last year of 36,179,783 net tons or 8.7 per cent. This tremendous increase over last year was really brought about during the months of July, August and September, the increase during this period amounting to 24,234,681 net tons or 17.4 per cent., and more than doubled the improvement that occurred during the first six months of the calendar year, the increase during this period over last year amounting to but 11,945,102 net tons, or 4.4 per cent.

For the week ended Oct. 12, 1918, production of anthracite is estimated at 1,955,000 net tons, a decrease of 4.7 per cent. compared with the week of Oct. 5. The daily average during the current week of 326,000 net tons was lower than the daily average for the coal year to date during either 1918 or 1917. Total production for the coal year to date now amounts to 55,658,000 net tons compared with 54,683,000 net tons for 1917, an increase of 1.8 per cent.

Bituminous coal dumped at lake ports, (including bunker), during the week ended Oct. 12 exceeded the large tonnage dumped during the week preceding by 3.7 per cent. and is estimated at 1,240,848 net tons. Compared with the weekly average during the period July 1 to date, the current week's tonnage was 147,907 net tons or 13.5 per cent. in excess. The total dumping for the year to date now amounts to 23,940,060 net tons.

Shipments of bituminous coal to New England during the week ended Saturday morning, Oct. 12, are estimated at 465,350 net tons, a decrease compared with the week preceding of 20.9 per cent. Rail receipts during the week are estimated at 165,216 net tons, a decrease of 8.6 per cent. compared with the week preceding, and tidewater shipments which are estimated at 300,134 net tons, decreased 26.4 per cent. Shipments from New York and Philadelphia amounting to 81,774 net tons, decreased 32.6 per cent., from Baltimore, amounting to 42,727 net tons, decreased 35.3 per cent., and from Hampton Roads, amounting to 175,633 net tons, decreased 15.8 per cent. Shipments from Philadelphia during the week were extremely light, the tonnage reported above practically covering shipments from New York alone. The performance during the week ended Oct. 12 by both rail and water also fell considerably behind the weekly average for the coal year to date. Bituminous coal to New England for the coal year to date is estimated at 15,539,368 net tons, of which total receipts by rail are estimated at 5,932,754 net tons and tidewater shipments at 9,606,614 net tons.

Shipments from all tidewater harbors during the week ended Saturday morning, Oct. 12, amounting to 804,657 net tons, or 15.5 per cent. behind performance of the week preceding. All harbors report a falling off in tonnage loaded, Baltimore dropping behind 33.5 per cent. compared with the week preceding, New York and Philadelphia, 18.8 per cent. and Hampton Roads, 6.3 per cent. Current week's shipments from each harbor also fell behind the weekly average for the coal year to date. Estimates place the total shipments of bituminous coal from all harbors from Apr 1 to date at 25,238,928 net tons.

The production of beehive coke in the United States during the week ended Oct. 12 is estimated at 597,000 net tons, an increase over the week preceding of 23,000

net tons or approximately 4 per cent. The average production per working day during the current week is estimated at 99,000 net tons as against 96,000 net tons during the week preceding. The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke at 371,563 net tons, and the operation of their plants at 77 per cent. of their full time as against 75.5 per cent. during the week of Oct. 5. A slight improvement was reported in labor conditions during the week.

Operating conditions in the byproduct industry during the week ended Oct. 12 were approximately the same as reported by the operators for the week preceding. For the country as a whole the byproduct plants were operated for 91.9 per cent. of their full time and at a total loss of 8.1 per cent. The operators attributed a loss of 1.1 per cent. to shortage of byproduct coal, 0.6 per cent. to labor shortage, 5.3 per cent. to repairs to plants and 1.1 per cent. to other causes. Material improvement occurred during the week in Minnesota and New Jersey. In the former state the improvement is attributed to other causes while in New Jersey a better supply of byproduct coal and repairs to plants brought about increased production. Maryland was the lone state reporting falling off in production and is attributed by the operators to labor shortage.

BUSINESS OPINIONS

Marshall Field & Co.—Current wholesale distribution of dry goods is running slightly ahead of shipments for the same week in 1917. Road sales for at once delivery were about the same, while for those for future delivery were well in excess, especially for spring. Merchants have been in the market in slightly smaller numbers. Collections continue good.

Bradstreet's—The Government's win-the-war programme shows no let-up, and, indeed, increased efforts are being made to get out production, while at the same time orders have been issued to cut outputs in an additional number of lines that are deemed non-essential at this juncture, this policy being accepted as counter propaganda to the talk of an early peace. All advices continue to indicate marked paucity of labor or of crude materials, and where odd offerings of staple merchandise are made, ready absorption occurs.

The Iron Age—What would come to the steel industry from a sudden ending of the war has been a large factor in the trade comment of the week, yet not a disturbing one. Generally the view is taken that apart from shell steel, in which an early peace would cause some cancellations, the materials now most in demand would show no great falling off. Government shipbuilding would go on and rail and railroad equipment contracts would keep many mills busy for months. There is no abatement of the Government demand for shipments to France. A new order calls for 12,000 to 15,000 tons of portable track for France, or double the amount taken in the previous week for the same purpose.

American Wool and Cotton Reporter—The most important development of recent weeks in the wool situation occurred when H. E. Peabody, of the Textile Division of the War Industries Board, announced to the National Association of Spinners that it will be an absolute impossibility to apportion any amount of raw material to producers. It was stated that this condition will continue to Jan. 1, until a new tabulation is made of the raw material available, and that there was great uncertainty as to the possibility of release of raw material after Jan. 1. Thus the hopes of the manufacturers are dashed to the ground, at least for those manufacturers who had held to the opinion that wool in sufficient quantity was accumulating so that some allotment could be made. The cotton situation is decidedly uncertain.

Atlantic Seaboard

BOSTON

Receipts all-rail continue to sag. Embargoes still being placed against consumers who have been able recently to accumulate stocks. Water borne shipments fall off. Number of modern colliers now definitely withdrawn from coastwise service, but substitute craft not all arranged for as yet. Hampton Roads situation shows improved dispatch but fewer bottoms loading for New England. Tidewater ports at this end well stocked for the present. Contracts being offered for twelve-month periods. Movement of anthracite all-rail increases slightly over early October, but receipts by water show notable shrinkage. Influenza epidemic seriously affects shipments.

Bituminous—Commercial bituminous continues to show week by week a further reduction in movement all-rail to this territory, particularly from Central Pennsylvania. For the first seven days in October the average receipts at the five New England gateways were 407 cars daily, while for the next nine days the movement dropped to an average of 352. During the same period the receipts of railroad fuel have slightly increased, so that the total number of cars passing daily, railroad fuel and commercial bituminous combined, averages now but little over 550. This is a drop of 200 cars per day from the August average.

A large number of special requisitions placed through Fuel Administration channels have now been cancelled or suspended, but with the operators either these have been replaced by requisitions in favor of Government or special use at Tidewater piers, or shipments have been permitted to go forward on contract. In many cases shippers now free to start deliveries on contract find their consignees embargoed and are obliged either to seek orders from industries that are not embargoed or solicit railroad contracts. There are queries in the trade as to just what extent the fuel authorities will continue to shut off current requirements.

There is also a disposition to take into account the stocks of anthracite screenings now on hand at individual plants. There is a fallacy in this, for while there is hardly a plant that cannot run on bituminous alone there are extremely few cases where anthracite screenings can be used without a proportion of bituminous. In other words, to discontinue shipments of bituminous merely because a plant has an ample stock of barley would be rather a shortsighted procedure.

Receipts by water have also shown a marked decrease. This was only to be expected when heavy tonnages of Pocahontas were turned away from Tidewater and ordered to byproduct plants and for western requirements. And, again, there were indications when quite a number of the most serviceable modern colliers in the New England trade were provisionally requisitioned for overseas transport. These bottoms have now been definitely withdrawn from the coastwise trade, but boats to replace them have not yet been supplied to the extent needed.

At Hampton Roads the loading dispatch is tolerably good, except in rare instances. A large proportion of the coal available, however, is being taken for Government use, either naval or otherwise, and the number of bottoms loading for New England seems to be constantly growing less. There is no real alarm over this situation for the reason that stocks here are so favorable, especially on the part of those plants that depend more largely on water deliveries.

All the New England ports, on Long Island Sound as well as east of Cape Cod, are well stocked with bituminous and there is no present anxiety here over conditions at the loading ports. In fact, the discharging piers and all concerned with them are enjoying a welcome respite from unloading coal under pressure.

One of the unfailing signs of an easy market is now putting in its appearance. Contracts are already being offered for next year, but on a twelve months basis, from Oct. 1. There would probably be a mild sort of buying, were the delivery offered only to Apr. 1, but there is so much talk of the war drawing to an end that buyers hesitate to commit themselves to "Government price," for a period after Government price-fixing may have ceased.

Anthracite—Receipts of domestic sizes at the five gateways show a somewhat increased movement as compared with the first week of the month. The first seven days show an average of 406 cars, while the next ten days the average was something over 450 cars per day. The increase is probably caused in large part by the congestion at the New York piers.

Water-borne anthracite is coming forward more slowly and in less volume than at any previous time this year. Some of the congestion at the New York loading ports is due to other causes, but the big factor the past three weeks has been the influenza epidemic. To one of the companies this has continued to mean a loss of something like 10,000 tons each day. Not only is the coal not mined, because of sickness among the operatives, but train crews and pier men are also away from their places to such extent that coal is not brought to the piers except in dribbling quantities and even then there are vexatious delays in dumping. Barges are daily being taken away from some of the ports to load at other ports. The epidemic is past its high point in this vicinity, although it is still causing a serious loss in industrial output.

NEW YORK

Influenza reduces production and interrupts shipments. Dealers complain of lack of supplies while public calls for fuel. Cool weather and illness increase consumption. Buckwheat sizes in good supply. Bituminous market easier. Commercial coals in better supply. Storage regulations modified.

Anthracite—The ravages of influenza in the mining regions is being reflected in production and shipments with the result that less coal is being mined. Every town in the anthracite region is affected and many collieries are hard hit. All the producing companies are suffering from the lack of men and many of the mines have suspended operations at various times. Conditions have become so serious that physicians have been sent from this city into the coal fields to assist the local physicians in combating the disease.

The docks from which this market secures its fuel are also seriously affected. One instance of this is at South Amboy, where on Saturday last instead of a force of about 200 men being at work there were only between 35 and 40, the other men being at their homes victims of the epidemic.

Though the figures showing the number of cars dumped at the local docks during the week ending Oct. 18 indicate an increase over the previous week, the receipts by the local trade do not indicate that they are receiving anything like their requirements. For the seven-day period the cars dumped here aggregated 6050 cars, an increase of 896 cars over the previous week, the low record of the previous week having been caused by the explosion at Morgan, N. J., on Oct. 5, and which resulted in some of the docks being idle two days.

Most dealers complain of the lack of domestic coals. They have plenty of buckwheat and some pea, but the former is of no use for household purposes. They point out that consumers obeyed the mandate of the Fuel Administration last Spring and placed their orders for this winter's fuel. In many instances no deliveries have been made on these orders, although most of them were placed the early part of April, and consequently these customers are now without fuel enough to start their fires. In the meantime the public is being assured that everybody will be supplied with fuel sufficient to keep them warm, and the dealers are wondering where it is going to come from.

Egg, stove and chestnut are very short. Shippers say the demand for these sizes is far ahead of the supply, and the prospects for larger shipments are not encouraging now. These three sizes have been running in fairly good shape all summer, and while the dealers have many unfilled orders on their books, they have had an unusually busy summer and have put away in bins more coal than probably ever before during the summer months.

Pea coal is easy and much of this size is being substituted for the larger sizes where the customer permits.

Buckwheat and the smaller coals are plentiful. Considerable Buckwheat No. 1 is being stored for future use, while rice and barley are drugs on the market, certain individuals paring prices in order to move stocks. Most retail yards have more or less of these coal on hand.

Retail dealers are being seriously handicapped in their deliveries by the lack of help and the attitude of those who are employed. The latter in many instances refuse to put the coal into the customers bins although the order calls for it. Frequently the coal is dumped on the sidewalk and the customer is left alone to put it away as best he can.

Current quotations, per gross ton, f.o.b. tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individua
Broken	$6.75	$7.50	Buck	$5.10	$5.90
Egg	6.65	7.40	Rice	4.65	5.10
Stove	6.90	7.65	Barley	4.15	4.30
Chestnut	7.00	7.75	Boiler	4.60	
Pea	5.50	6.25			

Bituminous—There has been a decided improvement in the local bituminous situation. More coal is available and spot buyers have been able to pick up stray cargoes occasionally. This latter condition is not expected to continue indefinitely now that the Fuel Administration has amended the storage regulations and cool weather is approaching.

The revised regulations permit all classes of consumers, except those in Class 1 as defined by the War Industries Board, to increase their reserve stocks, and those heretofore not on the preference list are

authorized to lay in additional reserve supplies.

Dumpings have improved during the week ending Oct. 18, reports showing 6448 cars dumped as compared with 5507 cars the previous week, an increase of 941 cars. Reports from the mine fields show a pronounced reduction in production as a result of the influenza epidemic, the figures from Central Pennsylvania indicating a decrease of 70,000 tons.

Shipments into New England and along the Long Island Sound have suffered much owing to the lack of labor at the loading docks, and it was estimated that 75 vessels were idle because of the failure to get coal for those points.

The surplus of commercial coal here resulted in a much easier market. There were no hurry calls for shipments and many shippers have plenty of coal. There were reports that some shippers were shading prices in order to save demurrage charges, but these were hard to locate.

The bunker situation is on the ragged edge. If the weather should suddenly become cold the situation would be serious with the coals now available for this purpose. As it is no ships have as yet been held up because of the lack of fuel, but there is no surplus in case of emergency.

Current quotations, based on Government prices at the mines, net ton, f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite production seriously cut by influenza. Retailers also handicapped. Stove and nut in great demand. Public fails to take mixed egg and pea. City has 50 per cent. supply in cellars. Peddlers licensed. Price increase expected. Steam sizes drag, except buckwheat. Bituminous grows more plentiful. Non-war plants stocking up. Car supply equal to labor. Brokers to be investigated.

Anthracite—It has been a trying week for the entire trade. The production has been seriously cut, particularly in the Schuylkill region, and it is estimated that the loss at the present rate for a month will be close to one million tons. Reports show that each day more men are idle due to the prevailing epidemic of influenza, and the outlook for the immediate future is not bright. Some operators, such as the individuals, are especially hard hit, many of them suffering a loss of more than 50 per cent. of their tonnage. We know of a few instances of local dealers almost entirely dependent on such sources of supply, and they were almost out of business this week.

The dealers are all working shorthanded, and it has been noticed that many are hiring mere boys to tide over the emergency. The retail trade has been unable to properly care for the numerous hurry calls from homes where there is illness and no coal. They have done all in their power and have been put to considerable expense by delivering fractions of tons.

As for many weeks, stove and chestnut are in the most active demand and in the half-hearted coöperation of the public with the suggestion of the Fuel Administration to substitute a mixture of 60 per cent. egg and 40 per cent. pea for stove and nut. In fact, there are numerous dealers who have not sufficient stock of these two sizes to make any impression on their orders.

This week notice was issued to all peddlers and grocery stores handling coal by the bucket that they must procure a fuel administration license. The response was not very heavy at first, as many small dealers had such trouble in procuring supplies last winter that they are not liable to engage in the trade this year, and in addition many of them thought they were to be charged a license fee in addition to the regular city commercial license. The authorities have adopted a standard quarter-bushel bucket, with which all such dealers must provide themselves. The maximum price for nut has been fixed at 16c., with pea at 14c. Various other restrictions are placed about the business to assure fair treatment for the humble class of trade dependent upon this source for their fuel supply.

As to the steam sizes, we find that with heavy movement to the West and Canada buckwheat is well covered with orders. The smaller sizes drag and we have heard of rice price being cut. Culm moves very slowly. The situation on the latter two sizes is not relieved by the embargo on the sizes below buckwheat now effective on shipments to Port Reading. The explosion causing the closing of the piers at South Amboy also added to the difficulties of the small sizes.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous.—The past week has been one of the best periods for the receipt of coal experienced for many months. To make a plain statement, there has been plenty of soft coal. Of course, one reason for this has been that the labor shortage caused by the epidemic has in some respects made this condition somewhat imaginary instead of real, because of transfers necessitated by the inability of some concerns to unload promptly. Following the ruling of the National Administration the non-war industries took advantage of the situation and at this time are getting pretty fair stocks of fuel. The distribution committee, however, is holding strictly to its rules of not allowing those concerns with a maximum supply on hand to increase it. The operators report a car supply equal to the labor supply. So far the bituminous region has not been greatly affected by the epidemic, but there are numerous cases, and fears are expressed that they will experience the same difficulty as the mines in the east.

It is rumored that the fuel authorities are contemplating weeding out concerns doing a brokerage business, many of whom they claim are not legitimate. It is understood that a questionnaire will be sent to all concerns selling coal on a commission, and in this way it is hoped to discover those who are doing a bona fide business.

BALTIMORE

Influenza makes big inroads on coal production and coal handling. Bituminous situation becoming tight again. Mild weather prevents more serious conditions for moment in regard to anthracite, but trouble is predicted.

Bituminous—Mines, railroads and coal-handling agencies in this section have suffered greatly from the epidemic of influenza and la grippe, which from the Baltimore city population alone has been counting from 500 to 2000 new victims daily, with a death list running from 100 to 250 per day. Every coal office force and yard force has been depleted by the ravages of the disease. Every mining district sending coal here reports a lessened production due to hundreds of miners being ill. Some days the past week the Baltimore & Ohio R. R. had as many as 40 per cent. of its operating men off active duty, and the shipment of coal over the lines dropped from a normal of around 2400 cars a day to about 1000. The result has been a distinct tightening of the soft-coal business. From an easy state where most industries here were able to keep their allowed reserve of from 15 to 30 days untouched, a number have seen their small reserves nearly wiped out and are appealing for shipments. The tighter market has stopped the tendency to reject box-car coal and wait for open-top shipments, which have been scarce both on line and harbor shipment. At present there is practically no open-top car coal either at tide for ordinary business or on line delivery, and the fuel administration is having no trouble now in disposing of the box-car coal coming through to its account. In the matter of distribution through purchasing agents of this coal, the national fuel administration has modified a former order of June 15, which allowed the Maryland administrator to select the agent to bill for the coals distributed by his office to consumers, irrespective of the former connection of the consumer with a coal supplying agency. The new order directs that the consumer be allowed to designate the purchasing agent or agency to bill for the coal supplied through the fuel administration, which designated agency shall receive the 15c. a ton commission allowed by the Government.

Anthracite—Only continued warm weather has prevented a bad situation here in regard to hard coal supplies. Not only are there thousands of homes without coal, the state administrator estimating that there are still about 175,000 tons of undelivered orders on the books, in addition to a large tonnage order demand which is being refused by dealers, but many homes in which persons are desperately ill with pneumonia have no coal. The dealers here have for the time being dropped all thought of the two-thirds delivery plan, which even the fuel administration officials now admit was faulty and over-optimistic, and are giving coal in one- and two-ton lots. The chairman of the city coal committee of the fuel administration believes that all homes can be supplied with a ton or two before real winter arrives; coal dealers do not believe it possible to do this in view of the light arrivals. There was a little spurt in receipts for a few days last week, but the deliveries are again in the old rut and far below requirements. Nut and stove coal are particularly scarce here.

Lake Markets

PITTSBURGH

Lake shipments decreasing but will continue to Nov. 15. Spanish influenza curtailing production. Byproduct plants supplied only with difficulty.

The diversion of larger tonnages of coal to retail dealers, upon the recent request of the local fuel administrator, has been decreasing the tonnage of Pittsburgh district coal shipped in the lake trade. In the week ended Sept. 28 the district's lake shipments were 351,000 tons, the shipments decreasing to 326,000 tons the following week, while there have been further decreases since. Hopes are entertained that the shipments can be kept at fully 300,000 tons a week for the remainder of the season, and the present prospect is that lake shipments will continue until about Nov. 15, or approximately to the end of the season of navigation.

Spanish influenza did not affect coal production of the Pittsburgh district until about the middle of last week, when reports began to come in from various quarters of very material reductions in the working forces and fears are entertained that before the epidemic is over there will have been a considerable curtailment in production. Previous to the middle of last week production was at substantially the best rate the district has ever seen.

The Pittsburgh district is furnishing practically a full supply of coal to the byproduct coke plants that depend on the region, but is barely able to maintain the supply and there has been no surplus for some time past for stocking purposes. With lake shipments extended to the middle of November there will be little chance of stocking thereafter, as local consumption will be heavier on account of the season. The district has been furnishing to the Clairton byproduct plant the amount originally asked for, 900 tons a day, remainder of the Clairton coal coming from the Lower Connellsville region. With seven batteries of 64 ovens each in operation the plant is consuming altogether about 7000 tons of coal daily.

There is practically no free coal in the market, substantially all the coal produced going out on lake shipments or against contracts and allocations.

TORONTO

Movement of coal light owing to heavy shipments to Upper Lake. Conferences of coal dealers for relief of householders without fuel. Conservation measures urged. Situation well in hand.

The movement of coal toward this city is light, owing to the heavy shipments which are being made to the Upper Lakes prior to the close of navigation, after which a marked improvement in the supply is anticipated. The list of householders who have stated that they have absolutely no fuel numbers 12,000. A conference was recently held between the local fuel dealers, the Board of Control and the city Fuel Commissioner at which the dealers agreed to supply ton lots to those without fuel within two weeks, the orders being apportioned among the dealers. The deliveries are being made on specified days when the filling of regular orders is suspended. From now on and throughout the winter dealers will only make deliveries to supply ordinary demands and no one will be permitted to have a large supply on hand. Instructions on coal conservation will be issued to householders, and it is hoped that if the public follow the advice given to substitute soft-coal, coke and wood for anthracite as far as possible the winter will pass without hardship due to lack of fuel.

BUFFALO

Sickness in the mines reduces output. Bituminous is fairly plenty. Jobbers not gaining more business. Anthracite coming in slowly, going up the lakes at fair rate.

Bituminous—The output of coal at the mines is sure to be cut down seriously by the prevalence of influenza, but it is not possible to say now how serious the reduction is going to be. Every effort is being made to keep the men at work, but they cannot of course do the impossible. But for that the work would have gone on well and the output made to show an increase.

The work of the jobbers is still as hard and unpromising as ever. They see no future to their part of the trade till conditions change. In fact they say that the tendency is to turn over more and more of the business to the zone managers. Consumers so often find that they must appeal to the fuel authorities that they often go there at the outset, and in that case the jobbers seldom get into the trade at all.

The general report is of a fair supply of bituminous all over the country. It is believed that a steady increase has taken place for some time and that there is now considerably more in consumers' hands than there was a year ago. Unless production is now seriously cut down the winter will be entered in better shape than for some years. The trade is tranquil. Government prices are rarely, if ever varied, though the jobber has never been reconciled to his small share of the profits.

Anthracite—The local retailer and consumer are engaged in complaining that they are discriminated against and that the city is bound to suffer next winter if the amount brought here for consumption is not increased materially before long. They declare that large numbers of consumers, some of whom have had their orders in since spring, are without coal and that there is none for them yet. From that side of it the situation is serious.

The wholesale and Government side tells a radically different story. It is declared that Buffalo has more coal in cellars than ever before at this time of the year and that if the distribution has not been fairly made it is because some one has managed to get more than he should. The fuel administrator's office reports that it has been able to fill every emergency order coming from families where illness from influenza has occurred. It is supposed that the lake trade is now getting first attention and that when that is ended for the season a liberal amount will be left in Buffalo.

CLEVELAND

Peace talk and influenza have been the governing factors in the Cleveland coal markets for the past week, the former bringing to the forefront speculations on after-war trade and period of readjustment, and the latter cutting sharply into production at Ohio mines. Lake coal is coming forward at the fastest gait of the season. The domestic trade also is faring considerably better—for the moment.

Bituminous—Production at Ohio mines is being reduced from 10 to 50 per cent. by the epidemic of Spanish influenza, according to operators. Lack of adequate medical attendance is being felt, and in instances entire mines have been down two and three days at a stretch. At present, conditions are certain to grow much worse before they become better, it is believed.

Optimism that has marked the views of operators here recently shows no diminution. Industrial stock piles, on the whole, are the largest in several years. The retail trade now is getting close to 50 per cent. of its requirements, and at least 75 per cent. of the homes in northern Ohio now have half or more of the soft coal they will need this winter. All told, there is more bituminous in northern Ohio today than for some time past, operators generally declare, and short of a disastrously bad winter no severe fuel shortage is possible. One operator goes so far as to predict that there will be a short market after Great Lakes navigation closes—about the middle of December—though he does not expect to see prices shaded much, if at all.

Anthracite—A thousand cars of anthracite in both November and December will see Cleveland's allotment for this year all in hand. Total shipments are estimated to be about 50,000 tons to date, but the city's proportion is only 40 per cent. of its normal requirements. Considerable No. 1 buckwheat has been coming in lately, but this grade is not very much sought. Receipts have been quite spotted, some dealers complaining they have not received over a half dozen cars in the past six months, while others have received a very fair percentage of their needs.

Lake Trade—Bituminous offerings at lower lake ports have been liberal the past week, but the tonnage loaded by the docks in the week ended Oct. 19 falls behind that of the week ended Oct. 12, which final official figures will show a record one for the season. Last week the docks were handling an average of 4000 cars or better a day, and the week's total hovers around the 1,200,000-ton mark. This week it has fallen to about the 1,000,000-ton mark. The first half of October has seen more than 2,000,000 tons loaded for the Northwest, while the entire month is calling for only 3,500,000 tons, according to schedule. Forest fires back of Duluth have lengthened the turn around at the head of the lakes, and the fleet will be found ultimately to have lost four or five days' time. Where a month ago operators were desparing of giving the Northwest its desired 28,000,000 tons, they now are being warned they must hold back some bituminous in order to provide ballast for the carriers that are going to make December trips.

DETROIT

Demand for steam coal appears easier, though supply is not excessive. Weather favors domestic consumers. Lake movement holds good volume.

Bituminous—Detroit consumers of steam coal are manifesting less active interest in the market than heretofore. Their easier attitude is attributed by jobbers to the fact that a number of the larger buyers have been successful in accumulating reserves of some size, while smaller concerns also have been able to get supplies in excess of current requirements. As the movement of coal from West Virginia and Ohio, available for use of steam plant, is now limited to slack and not very much of this is coming from West Virginia, the supply nearly offsets buying. Mines in Illinois are sending forward lump and prepared sizes more liberally. While the coal is not the state's best product, it is finding a market both with steam plants and with retailers.

But for the continuance of moderate temperatures many domestic consumers would be experiencing the hardship of fuelless homes. The domestic supply has been augmented by adding mine-run to the stock which mines in West Virginia and Ohio are permitted to ship to retail dealers serving household consumers. This compensates only in part for the continued scarcity of good domestic lump and prepared sizes, which are moving to the lakes under priority orders. There is still an urgent inquiry from domestic buyers, which suggests that many homes are yet without winter coal supply.

Anthracite—Representatives of the state fuel administration says a slight improvement is noted in receipts of anthracite the first two weeks of October compared with the similar period of September. The supply is still light, however. Of the 53,000 baseburner users whose applications for anthracite were received by the state fuel administration during the first ten days of September, approximately 23,000 have received delivery of sufficient anthracite to start the winter. The remaining orders, it is reported, are being filled at the rate of about 2000 daily. Should anthracite shipments continue at the present rate it is believed the baseburner users will be provided for within a month or six weeks.

Lake Trade—Shipments over lake routes are being facilitated by the plan under which dispatch of carriers is improved by assigning them to head of the lakes docks having speedy unloading plants. Cargo loading for the week ending Oct. 12 is reported to have been the heaviest of this season for a similar period. Shipments are likely to continue until Dec. 1 or later.

COLUMBUS

The Spanish influenza which is prevalent in many parts of Ohio is cutting production in all of the coal fields, but the reduction is not as great as might be expected. Miners are showing more patriotism and as a result the output is still good.

Production is being curtailed because of a great deal of sickness, due primarily to the epidemic of influenza. But miners are showing a good spirit because of the patriotic campaign which has been waged by James H. Pritchard, production manager for Southern Ohio, and are producing a good tonnage. The car supply is generally better. Production has been averaging about 75 to 80 per cent. of capacity in many of the producing fields of the state. Eastern Ohio is having a better car supply and as a result the output is better. Labor shortage is still having a bad effect on tonnage.

Domestic trade is still active and dealers are now accumulating surplus stocks in order to be in a position to take care of the rush when the mercury suddenly falls. There are fairly large stock of mine-run in the retail yards, and dealers are refusing to take that grade. Lump is being moved in limited quantities. The retail situation is generally good and little trouble is expected during the coming winter. Retail prices are firm at Government levels. Pocahontas is now out of the market and there is little anthracite to be had. Consumers in central Ohio are depending largely upon coal from the Hocking Valley and Pomeroy Bend fields.

The steam business is still a little soft because of the large production of screenings and mine-run which are not permitted to be shipped into the entire state of Michigan, the natural market; but modifications of the recent embargo have relieved the situation to a certain extent. It is reported that some producers are cutting prices of screenings, but these cases are isolated and will not affect the trade to any extent.

CINCINNATI

Domestic consumers are well supplied, and although influenza is hampering mining and transportation, other demand is also well taken care of. There is a fair car supply.

The coldest weather of the season has prevailed during the past week in this section, necessitating continued consumption of coal for heating purposes by householders, hotels, apartments, office buildings and the like. The extent to which summer storage, so often commented upon in these columns during the past few months, has taken care of this expected situation is indicated by the fact that there is no great rush to buy coal, but rather an actual let-up in demand, as compared with recent weeks. The average domestic consumer, in particular, is well taken care of, houses with basement furnaces being as a rule provided with very nearly their winter's supply of fuel, furnishing a decidedly good and unusual situation.

On the other hand, the industrial market has become a trifle soft in this vicinity, perhaps for the first time in several months, on account of the successful efforts of the mines to forward domestic coal and a correspondingly large production of screenings. As the zone system limits coal from a given section to a given zone, a slight over-supply may, and at this time does, exist in this vicinity, although of course this does not mean that there is an oversupply of any variety of fuel, taking the country as a whole. The general prevalence of the so-called Spanish influenza has to some extent affected production at the mines, as well as the operation of trains, as many men have been seized with the disease; but so far this is not a serious factor in the situation, and it is hoped, with the vigorous preventive measures that have been taken, that it will not become so.

LOUISVILLE

Car supply fine, but influenza epidemic is holding back production. Mild weather creating some surplus of Western Kentucky domestic. Steam generally draggy.

Reports from all sections of Kentucky show that the car supply is adequate. While reports show that last week proved a big one in production for the country as a whole, in this district output was smaller due to illness in the camps. The influenza epidemic and diphtheria have caused a shortage of labor in some of the eastern Kentucky districts.

Mild weather has curtailed retail business materially, and for the first time in many months the retailers are beginning to advertise in the newspapers for business. The small concerns and newer organizations have been advertising steadily to build up business, but even the large established organizations are now going to printers' ink as surplus stocks are being unloaded in the yards. However, the western Kentucky mines are meeting with such a good demand for coal at the powder plant at Nashville, Tenn., that they are shipping mine-run to that point instead of overloading the market, as there is little demand for any grade of western Kentucky just now.

Eastern Kentucky lump is in demand, but none of this grade is coming on the Louisville market. Some screenings and mine-run are to be had, but no lump.

Practically no West Virginia coal has come to Louisville by the river since the first few days of the month. Low stages have made it impossible to bring coal down, there having been very few rains, and no artificial tides created. River coal companies at present are depending on western Kentucky rail shipments.

Steam coal of all grades appear to be a bit draggy on the Louisville market just now. The eastern Kentucky producers are

meeting with a fair demand for good gas and byproduct coal, but even with regulations modified on stocking are not securing enough business on screenings to enable them to produce much lump. Coal from the Elkhorn district is moving principally to byproducts plant. Harland and southeastern Kentucky coal is moving to the lakes and also to Georgia and the Carolinas for domestic, industrial and general use. This coal is only moving to Michigan for gas and byproduct consumption.

BIRMINGHAM

Coal production showing some improvement. Car supply satisfactory in most instances. Steam demand very easy. Domestic market brisk.

Reports from this field indicate that a gradual improvement may be expected from now on in the output of coal. For the week ending Oct. 5, 409,022 net tons were mined, according to official tabulations of District Representative Holmes, which was an increase of about 26,000 tons over the week of Sept. 28. Car service during the past week was good, and only in a few cases was any delay occasioned at mines on account of lack of equipment for loading. Production at some mines is being affected by the presence of influenza in the camps, but this disease has not assumed an epidemic stage to such an extent as to cripple operations seriously.

Small industries are apparently fairly well supplied with fuel and are not clamoring vigorously for shipments above quotas specified in orders. All priority orders of railroads were cancelled by the Fuel Administrator, effective Oct. 14, shippers being instructed to continue deliveries on the basis of priority stipulations in effect for the week ending Oct. 12. Though the market is easy there is no surplus coal for the spot trade.

Domestic sizes are in great demand and there is a deficit in the supply to meet present requirements. Official reports show that approximately 21,000 net tons was purchased and stored during September. Yards are still without stocks and unprepared for the cooler weather which will soon set in.

Coke

CONNELLSVILLE

Slight decrease in coke production, with prepondering increase in raw coal shipments. Coke quality improving somewhat. Market quiet.

Coke production in the region has shown a further though slight decrease, but this is possibly equalized by increased shipments of coal, as the major portion of the coal shipments are to byproduct coking plants. Spanish influenza is beginning to curtail working forces and more serious effects are expected from the epidemic before it is over.

Reports from blasts furnaces as to quality of coke received from beehive ovens continue of a favorable character, but there is still much improvement to be sought. Some furnaces, receiving coke from several different operations, report distinct improvement in coke from some plants and none whatever in coke from other plants. Nearly all blast furnacemen agree that the quality of much of the beehive coke received is far below former standards. There is complaint of high ash in the case of many cokes, of high sulphur in a few cases, and of coke being of too small size from many if not the majority of machine drawing plants. The number of plants using mechanical drawers has increased since labor became so scarce. There is practically no complaint as to quality of byproduct coke.

Practically all the blast furnaces seem to be sufficiently supplied with coke, in point of tonnage, but there is little if any opportunity to accumulate reserves. It is very rarely that furnace coke is offered on the market, and there are few fresh allocations, as deliveries continue to be made on old allocations. Foundry coke is offered in a limited way, some of it through brokers, who are generally able to collect a commission of 25c. from the sellers. Coke screenings from old dumps continue to be offered, but in smaller volume than before the Government price limit was reduced.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Oct. 12 at 322,920 tons, a decrease of 7240 tons, and raw coal shipments from the two regions at 266,533 tons, an increase of 42,867 tons.

Middle Western

GENERAL REVIEW

Middle West mines producing record tonnages. Railroads not storing any coal, and result is a weak market. Central and northern Illinois mines in need of more business. Domestic trade shows improvement.

The entire Mid-Western coal-producing territory has apparently set out to please the Fuel Administration, as the tonnage produced from this district in the last week is going to equal, if not exceed, previous records. It is quite true that many favorable factors have helped the operators. For instance, plenty of cars, mild weather, and a fairly good labor situation. To counterbalance these things, the market continues weak, and at times erratic, and some operators are fearing a general epidemic of Spanish influenza in the mining districts.

To get back to present market conditions, the concensus of opinion is that there will probably be a break. With the enormous tonnage produced, and the present restricted zones, it is easily seen that something will have to happen, if the market is to remain firm. The railroads are not buying coal in any great quantities; in fact, it is said that only a few of the Northern railroads are in the market at all. The fact that the railroads are not purchasing coal, nor have they any in storage, accounts for in the opinion of many operators, the present weak market:

The southern Illinois field, considered as a unit, is well supplied with orders; in fact, the miners in this district have been behind on their shipments for over a year. Last week southern Illinois coal was easier than it had been for some time, but this condition has changed, owing to purchases made by a large public utility organization, and one or two railroads who have been temporarily in the market. Domestic sizes from Franklin, Williamson and Saline County are almost impossible to get, in spite of the fact that the average retailer has apparently as much coal as is needed for the present.

Central and northern Illinois producing districts are in need of more business. Even 6-in. lump and other domestic sizes can be freely purchased at Government price, while mine-run and screenings can be purchased considerably below that figure. The situation in Indiana is practically the same, with the exception, of course, of the Clinton No. 4 district, and one or two other fields producing very high grade fuels.

There is some little improvement in the domestic trade, as a number of retail dealers in the Northwest have come into the market with substantial orders. As the season progresses, and the hope of obtaining hard coal and high-grade eastern coals grows less, the retail trade will have to limit their purchases more and more to mines in Illinois and Indiana, rather than to the dock companies at the head of lakes, and the eastern producers.

CHICAGO

Almost impossible to sell steam coal. Domestic situation in bituminous is dull. Anthracite situation getting worse.

Chicago is proving a poor place these days in which to sell coal. It is almost impossible to place steam coal here, except at a discount from the Government price. Some of the biggest buyers are entirely out of the market, except when offered a decided bargain, and nine times out of ten are only interested on that basis, on the grounds of a personal favor. In short, if an operator has coal that must be sold, Chicago is a poor place in which to sell it.

The domestic situation is dull, so far as bituminous coal is concerned. All reports indicate that operators are receiving instructions to hold up shipments. The retailers claim that the spell of mild weather the city has been enjoying for the past few weeks has put a temporary stop to all buying. The anthracite situation is getting worse, rather than improving. It appears that all shipments of anthracite are being handled by the State Fuel Administration, and the way this organization is managing the job is causing a lot of adverse criticism. There is no indication either of any prompt relief of this hard coal situation.

MILWAUKEE

Mild weather dispels uneasiness in coal circles. Liberal receipts of anthracite by rail. Half of Wisconsin's supply in the hands of dealers.

The prevalance of mild weather, together with liberal receipts of anthracite by rail, tends to dispel uneasiness in coal circles. It is estimated that each day of the present weather saves about 6000 tons of fuel in Milwaukee. Between 300 and 400 tons of hard coal have been coming in daily by rail of late. No attempt is being made to store this coal, but it is passed right out to small dealers, who are thus enabled to make satisfactory inroads on delayed orders. About six weeks of lake navigation remain. During that period the receipts of anthracite will have to be above the normal if orders now on the books are to be supplied.

According to figures compiled at the office of the state fuel administrator, 50 per cent. of the coal ordered in Wisconsin for the winter of 1918-19 has already been delivered to dealers for distribution.

A statistical plan whereby it will be possible to prevent congestion of coal cars at any point and which will enable fuel administrators to tell at a glance where coal is needed most, has been perfected by Paul J. Weirich, of Monroe, Wis., fuel administrator for Green County. By the adoption of this system every county will receive equal distribution, and there will be no hardship because of improper consignment of fuel by administrators. No order will be filled unless the charts are consulted. The plans have received special commendation from the Federal Fuel Administration office at Washington.

Appleton, Wis., a prominent manufacturing center of the Fox River Valley, is undergoing a coal panic, which only the reception of fuel supplies will abate. Many families are closing their homes and seeking apartments and hotels. There is no reason why this condition cannot be corrected, however.

Coal receipts by lake thus far in October aggregate 53,111 tons of anthracite and 200,072 tons of bituminous, making the season's receipts of the former thus far 514,539 tons, and of the latter 2,967,749 tons.

ST. LOUIS

Overproduction of all kinds of coal in the southern Illinois field, and St. Louis is glutted. No domestic business at all from city or country, and steam business extremely light. Unbilled coal worries operators. Plenty of equipment and transportation improved.

Contrary to general expectations, and at a time in the year when everybody is worried about securing enough coal, the condition here is just the reverse. If there is any worry it is about where coal is going to be placed and how the mines are going to be kept running. The retail coal business in St. Louis is absolutely at a standstill. Many of the larger dealers have from one-eighth to one-fourth of their equipment working and the rest idle.

General conditions throughout the country sections are much the same. Orders are not coming in and inquiries develop the fact that the yards have put in the bulk of the coal required for the next couple of months. This pertains to practically all kinds of coal—Standard, Mt. Olive and high grade—whereas a few weeks ago there was a shortage on all kinds.

Steam business is slow. There is no storing to speak of, and the big buyer, figuring on lower prices, is holding off buying as much as possible.

The operators in the Standard field are facing a critical period, and the only thing that is going to keep their organizations intact will be the railroad business. At the present time this is coming through in fairly good volume, and every effort is being put forth to secure nearly all of the tonnage from the Standard district.

In the Carterville district and also the Duquoin district the operators are slowly but surely catching up with their orders, and there has been some free coal offered from this field in the St. Louis market this week. Some of the larger dealers here have shut off their shipments, and for the first time since last February, when there was a slight lull in the market, Carterville coal is being offered by the shippers on the open market for prompt shipment. This condition was not anticipated by anybody a few months ago and was not expected to happen until sometime next spring.

Fuel Administrator for Missouri, Wallace Crossley, has asked the United States Fuel Administration at Washington to lift the restrictions on industrial plants in Missouri storing coal so that the tonnage for Missouri may be absorbed and business kept going. There are no eastern coals coming in and an extremely light tonnage of Arkansas.

The prices are the same as previously, excepting that Standard screenings are from $1.50 to $1.60 and 2-in. lump has broken to $2.30 and $2.40.

On some of the coals from the Williamson and Franklin County field a 10c. special preparation charge is in effect. Very little of this coal moves into this territory.

COAL AGE

Volume 14 New York, October 31, 1918 Number 18

The Enlistment of Shorty McGee

By Gilbert Fletcher

I WANTED to jine with the army,
Or the navy, said Shorty McGee,
But the guys what was doin' recruitin'
Didn't seem to be crazy fer me.
They kicked 'cause I wasn't a scholar,
They said I was way under size,
And they hung out the crape on my cravings,
When they found I was weak in the eyes.

SO I pulled my freight back to the pit mouth,
To the gloom and a rank smellin' hole,
With a cuss at my eyes and my inches,
And an oath at the tools and the coal.
And wrath, plain wrath fer the thick heads
That headed a runt fer the mine,
And gave him a pick and a shovel
When he asked fer a gun in the line.

IT was coal that they wanted to win it,
So I'm gettin' it out on the run,
And it's keeping things warm fer the Allies
And it's making them hot fer the Hun.

Yea boy, it's a line I'm a-holdin',
Jest bet yer best boots I will stick,
Fer if I can't shoot I can shovel,
I can blast and can handle the pick.

I'M wading coal out by the carload,
Too busy to stop or to strike,
I'm doing my bit fer the Allies
A-workin' the way I would fight.
Each lump that I throw in the coal car
Is a missile slam-bang to its mark,
It ain't any haphazard business
Like chucking grenades in the dark.

IF I am a bit short fer a soldier,
And my eyes seem to be on the bum,
I can delve into coal with a shovel,
With the zeal I would carry a gun.
So it's stick to the diggin's fer us boys,
And sure we'll be doin' two bits,
In keeping things right fer the Allies
By coaling up Hades fer Fritz.

Peabody Coal Development in Central Illinois

By GEORGE W. HARRIS
Editorial Staff, "Coal Age"

FIG. 1. TIPPLE AT MINE NO. 7 OF THE PEABODY COAL CO., KINCAID, ILLINOIS

BIG coal producers do not spring up overnight like mushrooms. Neither do they continue in the first class unless the management provides for systematic development along uptodate lines in which full advantage is taken of every opportunity to secure tonnage. It is interesting to note how the leaders do things. In a coal state of the importance and potentiality of Illinois, there are a number of large coal interests which have under way some big plants in different stages of development. Among these mining companies is the Peabody Coal Co., one of the leading miners and shippers of the state as regards modern equipment and aggregate tonnage; its eleven mines shipped 4,310,000 tons for the year ended Dec. 31, 1917.

PROMINENT among the mines of the Peabody Coal Co., of Chicago, Ill., is a group of plants on the Chicago & Illinois Midland R.R., within 20 miles of Springfield, Ill. This short line of road does not attract much attention on the Chicago or New York exchanges, but it is of far more interest to the Peabody company than some of the big railroads which are prominent at these stock exchange centers. The Chicago & Illinois Midland R.R. interchanges with the Baltimore & Ohio and the Wabash R.R. at Taylorville to the east, with the Illinois Central at Pawnee Junction, with the Chicago & Alton at Auburn, and the Chicago & Northwestern at Compro, to the west of the plants in question. This belt line of about 26 miles in length furnishes traffic connection for the Peabody mines along the line of the road with the trunk railroads noted. Seven miles west of Taylorville on the Central & Illinois Midland R.R. is the mining town of Kincaid; to the east of this town is the No. 7 mine of the Peabody Coal Co., to the west is No. 8, and about halfway between Kincaid and Taylorville is No. 9—the latter in embryo.

Standardization of machine parts has been practiced in this country for some time, but the same policy seems somewhat novel when applied to coal plants. Nevertheless this principle seems to have been adopted in the case of the three plants just noted. No. 7 main shaft was sunk in the fall of 1911 and is 349 ft. deep to the No. 6 seam; shaft No. 8 was sunk the following year, reaching coal at a depth of 358 ft.; No. 9 has only recently struck coal at 417 ft. below the surface. The No. 7 and No. 8 shafts and equipment are in duplicate practically in every particular, and No. 9 is laid out on the same lines. It would hardly be practicable to carry out a plan of this kind in some mining sections. But in the prairie state of Illinois the surface topography permits of plant location almost

at will, and the regular seams readily adapt themselves to a standard plan of development.

The No. 7 and No. 8 mines of the Peabody Coal Co. are in Christian County. These two plants and a third mine at Stonington (Peabody No. 21), eight miles northeast of Taylorville, produced 1,747,292 tons of coal for the year ended June 30, 1917. This tonnage was all machine-mined. By contrast the remaining six commercial shipping mines in this county produced only 1,074,875 tons during the same period; and of this amount only half the product of one mine (34,382 tons) was machine-mined coal—practically the whole output was mined by hand. In view of the fact that Peabody No. 7 and No. 8 mines

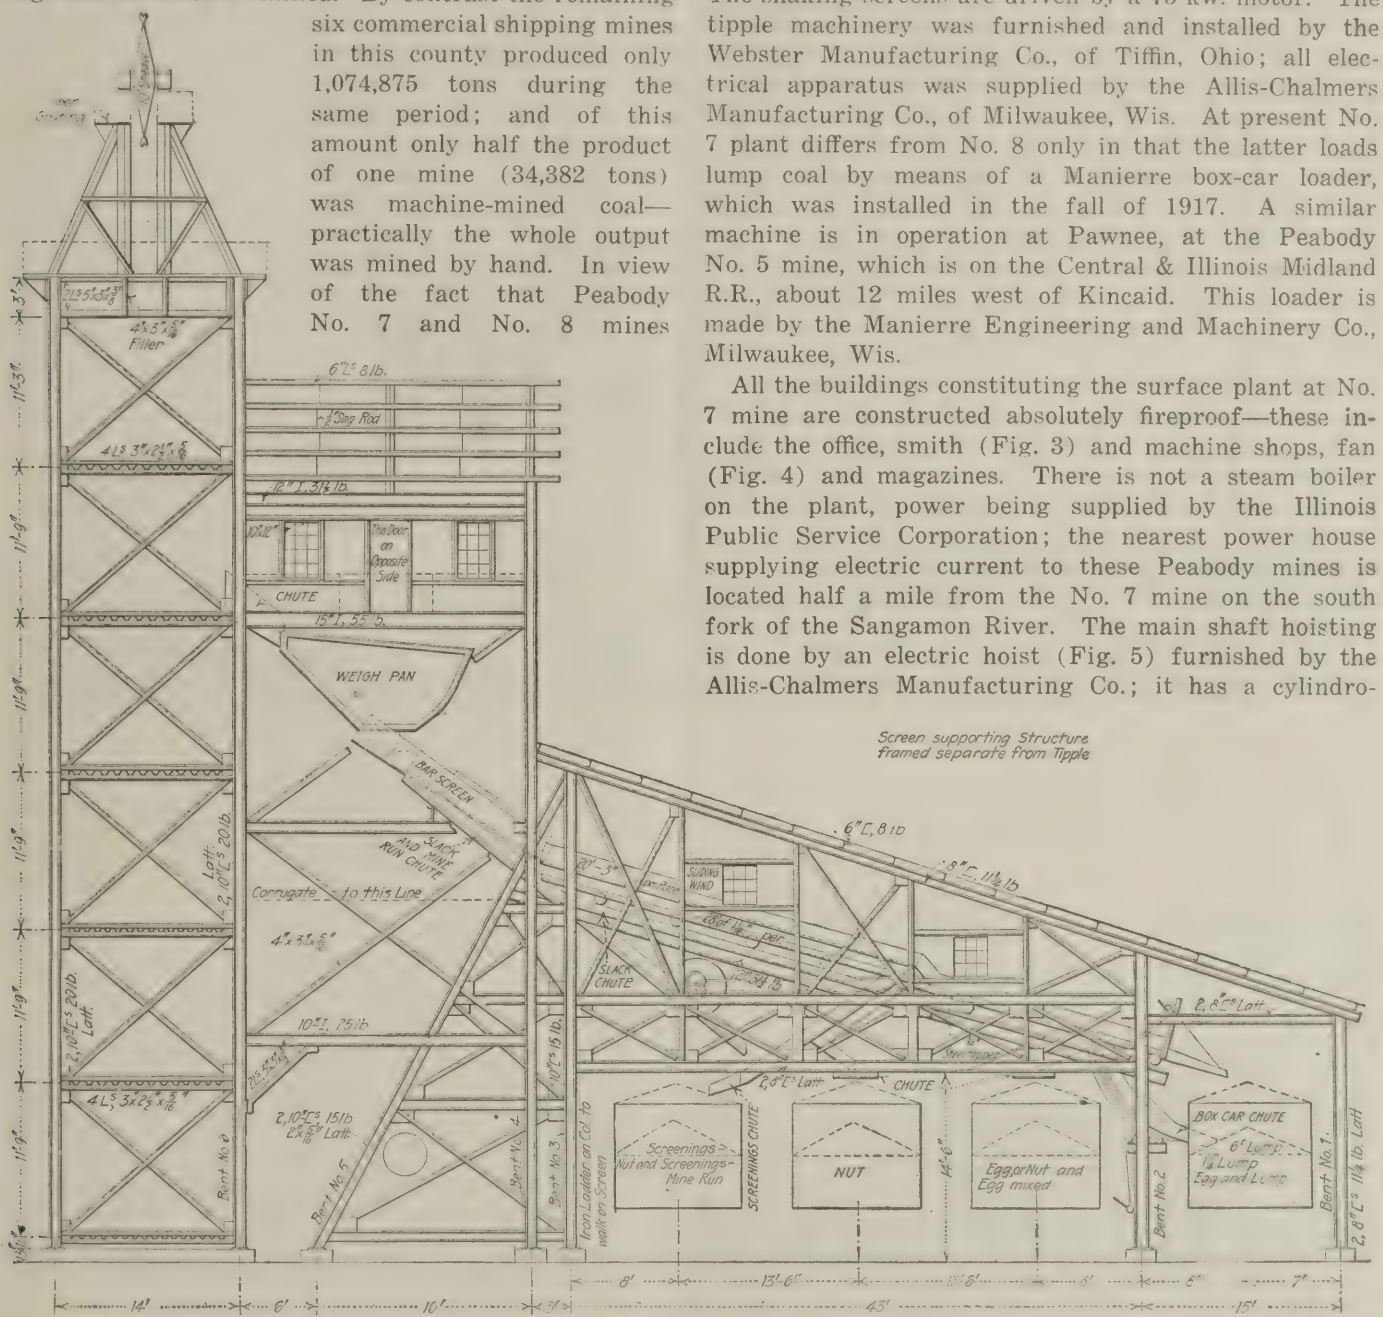

FIG. 2. LONGITUDINAL SECTION OF HEAD FRAME AND TIPPLE, SHOWING LOCATION OF CHUTES AT MINE NO. 7, PEABODY COAL COMPANY

are duplicates of each other, only the No. 7 plant is illustrated and described in this article. The capacity of No. 7 mine is 4000 tons of coal in eight hours. The tipple at this mine is shown in perspective in Figs. 1 and 3, and in section in Fig. 2. The tipple is steel throughout and most of the main members are of built-up construction. The main posts and beams are latticed channels; other members are built up with angles and lacing, and some I-beams are used as struts The main tipple is covered with corrugated-iron siding, as shown in the illustrations. From the surface to the center of the sheave wheel at the shaft is a distance of 90 ft. The tipple was built by the Decatur Bridge Co., of Decatur, Illinois.

The arrangement of the screens and the sizes and grades of coal loaded at this four-track tipple are shown on the section, Fig. 2. The screen-supporting structure is framed separate from the rest of the tipple. The shaking screens are driven by a 75-kw. motor. The tipple machinery was furnished and installed by the Webster Manufacturing Co., of Tiffin, Ohio; all electrical apparatus was supplied by the Allis-Chalmers Manufacturing Co., of Milwaukee, Wis. At present No. 7 plant differs from No. 8 only in that the latter loads lump coal by means of a Manierre box-car loader, which was installed in the fall of 1917. A similar machine is in operation at Pawnee, at the Peabody No. 5 mine, which is on the Central & Illinois Midland R.R., about 12 miles west of Kincaid. This loader is made by the Manierre Engineering and Machinery Co., Milwaukee, Wis.

All the buildings constituting the surface plant at No. 7 mine are constructed absolutely fireproof—these include the office, smith (Fig. 3) and machine shops, fan (Fig. 4) and magazines. There is not a steam boiler on the plant, power being supplied by the Illinois Public Service Corporation; the nearest power house supplying electric current to these Peabody mines is located half a mile from the No. 7 mine on the south fork of the Sangamon River. The main shaft hoisting is done by an electric hoist (Fig. 5) furnished by the Allis-Chalmers Manufacturing Co.; it has a cylindro-conical drum and is equipped with modern safety devices.

On descending the shaft the same modern construction evident about the rest of the plant can be noted—in the concrete lining, the steel I-beam buntons and the 70-lb. T-rail guides. The main shaft is 17 ft. 8 in. by 10 ft. in dimension; the air shaft measures 16 x 10 ft. inside—there is a 10 x 10-ft. air compartment and a 6 x 10-ft. stairway partitioned off by a 6-in. concrete curtain wall. The air shaft is concrete throughout. The 12-ft. Jeffrey steel-cased fan at this shaft

runs at high speed and supplies 250,000 cu.ft. of air per minute to the mine workings.

A strategic point about a high production plant is the shaft bottom. Through this lower end of the bottle's neck passes the tonnage of the mine, and any congestion here limits the production of the plant. The capacity of the shaft is greatly increased by attention to details of hoisting, haulage and the facilities at and around the bottom itself.

All these factors so vitally affecting the shipment of coal are interdependent. In Fig. 6 is shown the bottom at No. 7 mine viewed from the empty side. The diamond cross-over is prominent in the foreground. On

Four-ton end-gate cars are used. In order to get the proper grades at the loaded and empty tracks, bottom rock was blown up on either side of the shaft; side retaining walls of concrete were then built, on top of which were set 12 x 12-in. posts to support the 12-in. I-beams holding up the limestone roof. All these features are brought out in Fig. 6. This illustration shows that the local underground artist has improved his opportunity to decorate the concrete side retaining walls with frescoes—someone also had a literary turn of mind.

The No. 6 seam at this group of Peabody mines has an average thickness of 7 ft. 6 in. and a good top.

FIG. 3. BLACKSMITH SHOP AND TIPPLE AT MINE NO. 7 OF PEABODY COAL COMPANY—ALL FIREPROOF

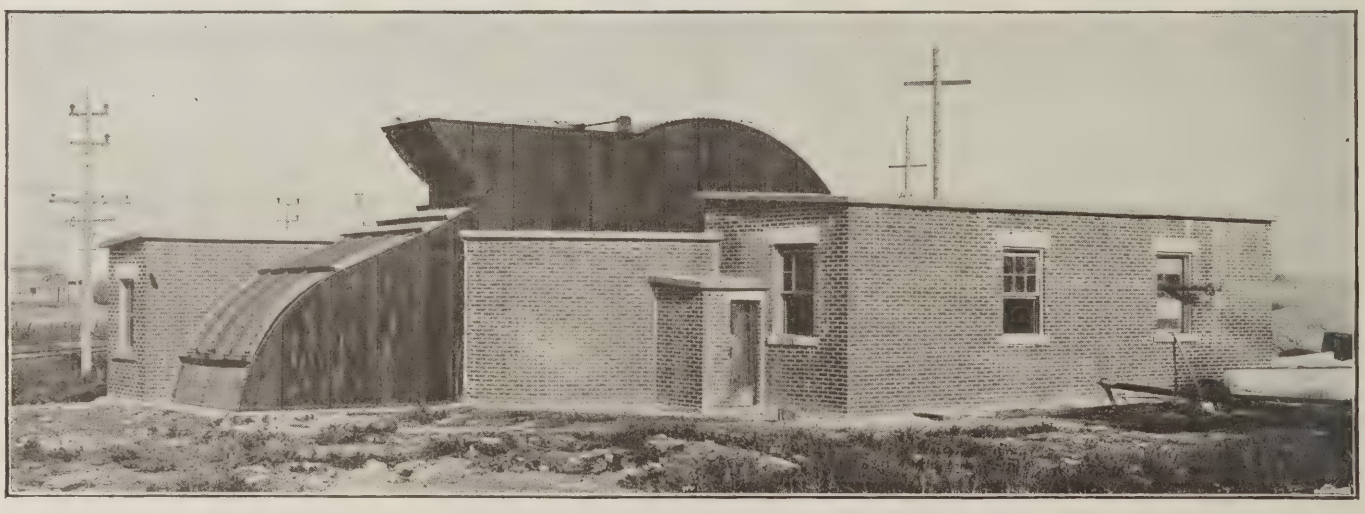

FIG. 4. FAN AT MINE NO. 7 OF PEABODY COAL COMPANY

the opposite side of the shaft automatic safety mine-car cagers are installed, made by the Mining Safety Device Co., of Bowerston, Ohio.

Both loaded and empty cars are handled by gravity, the former being delivered on the Oleson self-dumping cages (made by the Eagle Iron Works, Des Moines, Iowa) by the automatic cager, a device contributing greatly to safety and speed of operation. The empty pit cars, pushed off the cage by the loaded ones, run onto the empty tracks and around to each side of the shaft by gravity; here they are made up into trips which are picked up by motors.

The mines here are worked on the room-and-pillar panel method of mining. The east and west main entries are driven on the three-entry system—a haulage way in the middle and an airway on either side. Double entries branch out from the main entries. A 100-ft. barrier pillar is left between the first room in a panel and the nearest entry. Rooms in one panel do not hole through at the face to the rooms of an opposite panel ahead. Rooms are driven on 55-ft. centers with 30-ft. room width and 25-ft. pillars; entries are 12 ft. wide.

All operations are conducted electrically at Mine

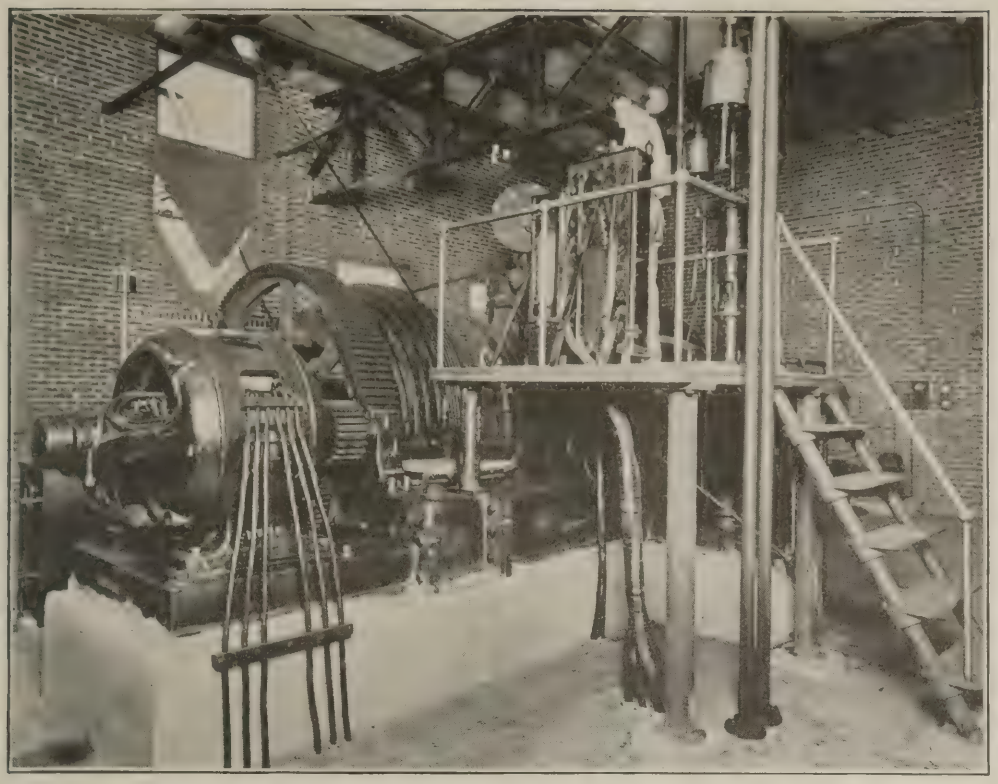

FIG. 5. MAIN HOIST AT MINE NO. 7, KINCAID, ILLINOIS

No. 7. On the surface this power is used as noted. Underground the haulage is done by General Electric motors—13-ton locomotives for main-line work and six-ton motors for gathering cars from rooms and delivering to partings. All coal is cut by electrical mining machines, distributed as follows: Twenty Sullivan shortwall machines are used on territory work and entries are driven by 12 Morgan-Gardner machines.

No pillars are drawn in this field, which is rather unfortunate. Everything being equal it costs no more to drive an entry looking to 90 per cent. recovery of coal in the territory opened up than for 50 per cent. The expense of narrow work charged up against 9000 tons of coal mined is considerably less per ton than when only 5000 tons are recovered. Many operators consider that coal of the thickness of that worked in Mine No. 7 is almost ideal as regards profitable mining. However, it is difficult to take full advantage of these favorable conditions at times. The same trouble is experienced here as in most other sections of Illinois, where a comparatively low percentage of coal recovery has been maintained.

According to the 1910 census reports, the average value of surface in Christian County, Illinois, is $123.63 per acre. This is among the best land in the state, and when subsidence of surface occurs as a result of mining which brings down the top then heavy damages are claimed by the owners of surface thus disturbed.

A natural consequence is to leave sufficient coal in the ground in the form of pillars which will prevent a break in or settlement of the top rock. This subject has been touched on in *Coal Age* before, but the importance of the matter is such that a further discussion of similar cases is warranted. A most interesting bulletin on the "Percentage of Extraction of Bituminous Coal with Special Reference to Illinois Conditions," by C. M. Young, of the University of Illinois, reports on the results of investigations which have been going on recently. This bulletin notes that in the district, of which Christian County is a part, the Peabody Coal Co. reports extractions at its mines of 65, 62, 60 and 70 per cent. respectively.

Every year the housing problem at mines receives more and more attention. The majority of the miners at No. 7 and No. 8 Peabody mines own their own homes, which were purchased from the company. The mining town of Kincaid is on the other side of the track from No. 7 shaft, and No. 8 is only 1½ miles distant; it has a population of about 2000. Building

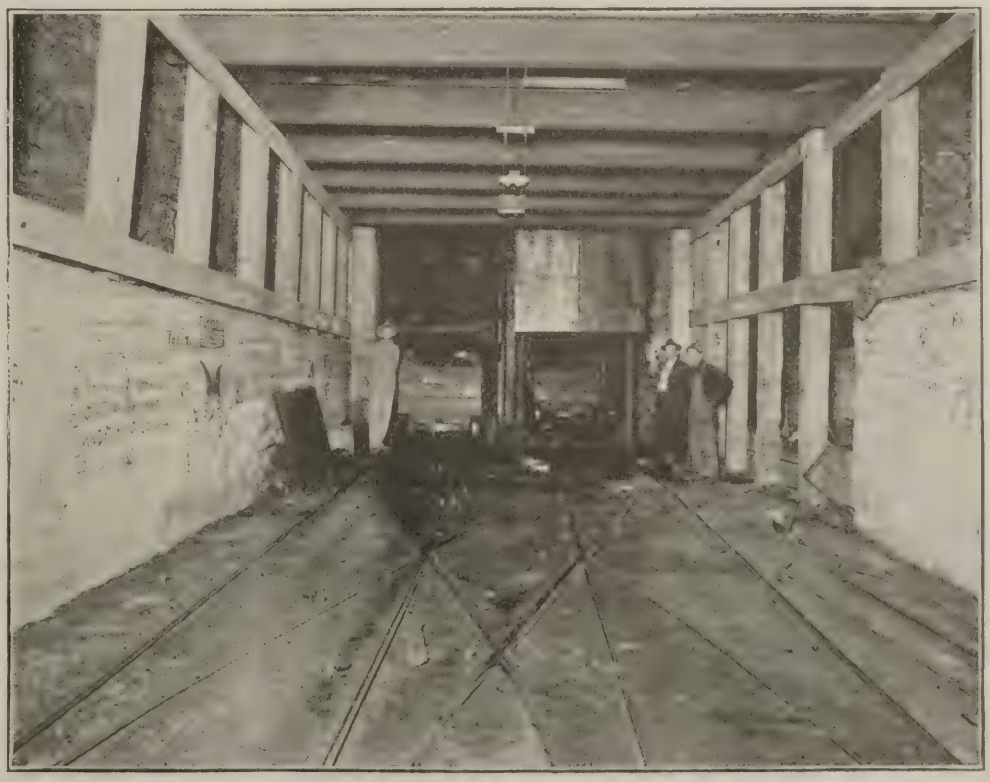

FIG. 6. SHAFT BOTTOM, EMPTY SIDE OF MINE NO. 7, PEABODY COAL COMPANY

restrictions are attached to transfers of land and vary according to the value and location of the lot. The restrictions include the erection of brick business buildings, the exclusion of saloons, gambling houses and so on. The miners can build their houses of wood. A hotel and a large foundry and machine shop have been built in the town; the latter is about to double its capacity.

Often of equal importance to an operator with the technical side of mining are commercial problems—markets and car supply. At present the market for a given coal is determined by the zoning system, and operators and men are struggling to the limit to supply coal. Dr. F. C. Honnold, Production Manager for Illinois, has stated that if the domestic consumer would accept all grades of coal it would greatly help production—that screenings on hand retard production. It is due to the discrimination of the private consumer of coal in Illinois as to the kind preferred which has led to the preparation of the "57 varieties" which have been placed on the market. One solution of the abnormal demand for domestic coal in Illinois, in Dr. Honnold's estimation, would be the acceptance of mine run by the private consumer—its use has been urged.

Now that production is receiving so much attention, all the factors entering into the tonnage problem are given most careful consideration. Prominent among these are labor and transportation, and they are much more closely related than might appear on the surface. It is now the policy of the Peabody company to provide an opportunity at each of its mines to ship over several roads. Miners tend to go to those mines where they can get the most steady work. The mines on the Central & Illinois Midland R.R. have had a particularly good car supply, operating at best from 75 to 80 per cent. of the time. It is difficult to hold men and keep up an efficient organization where the car supply is unsteady; when a mine works only two or three days a week it is not at all satisfactory to the miners, who leave and go to a mine where steady work is obtainable.

The Peabody company stated last spring that it had lost 20 to 30 per cent. of possible production on account of labor shortage due to insufficient car supply. The consumption of coal has increased enormously during the last two years; new mines have been opened up and existing plants have improved their facilities for increasing output. On the other hand, available labor of mining caliber has decreased, and the car renewals on the railroads have hardly more than replaced worn-out rolling stock. In view of the present tax on the facilities of the transportation lines in other directions, improved service will have to compensate for deficiencies in cars and locomotives if the operators are to ship the quantity of coal necessary to meet this year's requirements.

For the facts forming the basis of this article and the illustrations accompanying it, the writer is indebted to various officials of the Peabody Coal Co., who courteously furnished the information.

Soft Coal Loadings at Lake Erie Docks

To Oct. 1 the Great Lakes fleet had taken on exactly 20,756,057.04 net tons of bituminous coal for the Northwest, according to the official statement of the Coal and Ore Exchange, Cleveland. Since the Federal Fuel Administration's schedule calls for a total movement of 28,000,000 net tons of bituminous this season, and October is down for 3,500,000 tons and November for 2,400,000 tons, the Northwest is behind 1,343,942.96 tons. December, however, was left open by the Federal Fuel Administration, and since operators are figuring on moving at least as much coal as in last December—when the movement was about 660,000 tons—the lake trade is about 700,000 tons behind schedule.

In addition to the 20,756,057.04 tons of cargo coal loaded at Lake Erie ports for the season to Oct. 1 the total of vessel fuel loaded is 928,778.90 tons, making a grand total of 21,684,835.94 net tons of bituminous handled at the docks from the opening of navigation to the first of October.

Cargo coal loaded in September amounted to 4,666,545.10 tons and vessel fuel, 184,652.80 tons, making a total of 4,851,197.90 net tons for the month. The schedule called for 4,900,000 tons of cargo coal. Toledo again led, with a total of 1,754,641.15 tons at the three docks; Lorain was second with 608,186.80 tons; Ashtabula was third with 622,990.30 tons, and Cleveland fourth with 552,087.55 tons.

The accompanying table, the official compilation of the Coal and Ore Exchange, which is handling the Great Lakes vessel pool, gives the statistics in detail:

BITUMINOUS COAL LOADED AT LAKE ERIE DOCKS

Port	Dock	During September			Season to Sept. 30		
		Cargo	Vessel Fuel	Total	Cargo	Vessel Fuel	Total
Toledo	B. & O.	578,751.55	14,793.50	593,545.05	2,137,271.20	45,523.80	2,180,795.00

Erie	East.	84,953.65	4,055.35	89,009.00	512,942.45	30,651.20	543,593.65
Erie	Pa. West	80,848.85	4,825.70	85,674.55	332,988.80	10,009.00	342,997.80
Total		4,666,545.10	184,652.80	4,851,197.90	20,756,057.04	928,778.90	21,684,835.94

The bituminous coal movement by months, according to the Coal and Ore Exchange, has been as follows: April, 868,852.64 tons; May, 3,194,198.10; June, 3,539,-352.30; July, 4,234,305.05; August, 4.996,929.95, and September, 4,851,197.90. Vessel fuel is included in these figures.

If the 34,000,000 tons of coke made in beehive ovens in 1917 had been made in the byproduct type, some 750 million cubic feet of gas would have been saved, according to estimate, every 24 hours. From this gas about 65 million gallons of benzol might have been recovered.

Low-Temperature Distillation of Illinois and Indiana Coals

By G. W. TRAER

SYNOPSIS—*This article is an abstract of a paper presented at the October, 1918, meeting of the American Institute of Mining Engineers at Milwaukee. It gives an account of some remarkable results. A semi-coke averaging 18 per cent. volatile matter was made in cast-iron containers that were pushed consecutively through the ovens. By this process it is estimated that nearly 20 gal. of gasoline as well as other valuable byproducts can be made from one ton of Illinois coal.*

THE distillation of bituminous coals at what is commonly termed low temperature, and the quantities, nature and adaptabilities of the products evolved have been the subject of considerable experimentation during recent years. Fortunately, the earlier work in this country was done by men whose scientific training qualified them properly to record and interpret the results of their experiments. The work of Professor Parr, of the University of Illinois, is especially notable in this respect.

Professor Parr's work, added to that of English experimenters, demonstrated certain things to a degree which is generally regarded as convincing. They have proved that a caking bituminous coal, when subjected to a temperature of not more than 1000 deg. F. (preferably somewhat less) will yield light tar having low specific gravity (about 1.06) and high commercial value; also, that this yield, with a given coal, will depend upon the percentage of hydrocarbons in the coal, the maximum temperature used, and the promptness with which the distillate gases are removed. It is assumed that air is excluded from the retort, and that the coal is subjected to heat for a sufficient time to drive off all of the tarry hydrocarbons. It is the purpose in this paper to describe other work of a practical nature, directed toward the commercial adaptation of these principles, which was begun nearly two years ago; this investigation was assisted by A. J. Sayers, of the Link-Belt Co., and Carl Scholz.

The first step was to draft tentative designs for the handling of the coal and coke so as to produce a coke having a suitable structure for sizing, storage, shipment and handling, without the necessity of briquetting. Professor Parr's results had indicated that the rather open-pored volatile coke produced by him had a low ignition point, which would contribute toward easy control of the fire in stoves, house furnaces, fireboxes and boilers. It is recognized by those experienced in the marketing of fuels that the hard non-volatile coke from the high-temperature process falls far short of being an ideal domestic fuel. The high ignition point of hard non-volatile coke makes it difficult to burn satisfactorily in a small or thin fire. With a strong fire the drafts have to be watched closely because of the tendency to over-intensity of combustion. In spite of its high heat value and cleanliness in handling, it has therefore fallen short of being a popular domestic fuel.

Another important factor is that, while it has proved quite impracticable to use non-volatile hard coke in locomotives previously using high-volatile bituminous coals, without radical changes in the fireboxes, the indications were that high-volatile coke could be employed for this purpose without material firebox change.

C. M. Garland was retained to revise the designs and supervise the construction and operation of an experimental plant, which was installed at Chicago in 1917. The operation of the plant began early in October and, with some stoppages for corrections indicated by its use, was operated until Dec. 24. Altogether about 140 tons of coal were passed through the plant, about 100 tons of which was Franklin County mine-run crushed to pass through a 2-in. round-hole shaker screen. The other coals tested, in lots ranging from 4 to 12 tons, comprised those from Harrisburg and Eldorado in Saline County, Illinois; Indiana Fourth Vein from the J. K. Dering mine, Clinton, Ind.; Indiana No. 5 from Grant mine No. 4; and Indiana No. 5 from Knox County.

The plant comprised one oven or retort, together with the usual condensing and scrubbing apparatus for the distilled gas, and other necessary machinery and appliances. The oven was horizontal and rectangular, about 60 ft. long, 4 ft. high and 20 in. wide. At each end was a double-door lock, one serving for the admission and the other for the withdrawal of the containers carrying the coal, without admitting any substantial amount of air. These locks were of suitable length to hold one container; they were not heated, nor was a space of the same length as the lock immediately inside of it. The remainder of the retort was supplied with down-draft flues, each of which led to a large off-take flue in the base of the oven, and thence to the stack. The flues were about 1 ft. square in the clear and were laid with ordinary rectangular silica brick. As the volume of clean gas yielded by the low-temperature process is insufficient for heating the oven, provision was made to supply city gas for the additional heat necessary; a commercial plant producer gas would be supplied for this purpose.

A track was laid through the oven with 16-lb. steel rail, 11-in. gage, to carry the containers. These were introduced at intervals into the charging end, each successive container pushing forward those which had preceded it; when the retort was filled, a finished container would be discharged whenever a fresh one was inserted. The train of containers was pushed by a hydraulic ram. They were charged with coal and the coke was discharged from them manually. In a commercial plant the pushing would be done by an electric ram, and the charging and discharging would be mechanical. The container design was the central feature of the process. Those used in this experimental plant

were about 4 ft. long, 4 ft. high and 12 in. wide. Partitions, 12 in. apart, divided each box into four sections, each 12 in. square. Each box was placed on a cast-iron truck mounted on four cast-iron wheels. When the truck and box were removed from the oven, the box was lifted off, the coke discharged, the box replaced on the truck, and returned to the other end of the oven for recharging.

One of the principal purposes of this form of container was to afford means by which the heat could be quickly conveyed through the mass of coal. Experience with the high-temperature byproduct oven has shown that when heat is applied only to the side of the charge, the progress of coking is slow, only ½ in. per hour.

It is impracticable to make a semi-coke of substantially uniform volatile content, unless special means are employed for conveying the heat to the center of the charge more quickly than is possible by means of a heated side-wall only, because if the side-wall temperature is not raised above 1000 deg. F. the progress of the coking toward the center will be prohibitively slow. If the heat is raised above 100 deg. by the time the tarry volatiles are all driven off at the center of the charge, the volatile contents of the coke on the outer

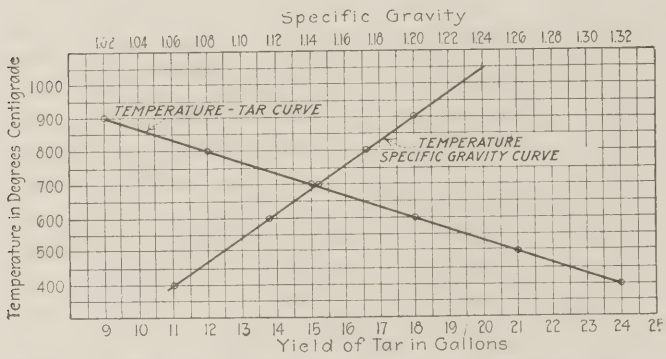

FIG. 1. RELATION BETWEEN COKING TEMPERATURE AND TAR PRODUCED
Coal contains 30 per cent. volatile matter

side will be greatly reduced, thus giving a coke of widely varying character. Furthermore, the higher temperature will cause a proportionate decrease in the valuable light oils and a corresponding increase in pitch; the percentage of coke also will be decreased. There will be an increase in gas, but it will fall far short of compensating for the losses mentioned.

The first container boxes were made of sheet steel, and were divided into four compartments each 12 in. square. It quickly developed that this column was too large for short-time coking, with a reasonably uniform volatile content. Additional compartments were then put in some of the boxes; while, in others, pipes of varying diameters were placed in the centers of the large compartments. Both of these expedients produced usable coke.

A cast-iron box also was used; the shell and partitions were ¾ in. thick, and the compartments varied from 4 to 8 in. in width. This cast-iron box showed great superiority over all other forms, and proved eminently satisfactory for the purpose. The compartments were tapered slightly, so that by the time the boxes reached the open air the temperature had been reduced enough to cause a slight shrinkage and the coke slipped out of the compartments without difficulty. It showed no tendency whatever to cling to the metal.

The semi-coke thus produced proved a most satisfactory fuel for all general purposes. Although the retort had only side-wall heat, a coke was produced that was practically homogeneous in structure and volatile content. By keeping the charge in the heat long enough, a hard coke with practically no volatile contents could be made; or by withdrawing the charge as soon as it was fused to the center, the coal could be changed into the form of coke while but little of the original volatile contents had been removed.

Experience indicates that the ideal fuel for general use is obtained by leaving about 18 per cent. of the volatile matter in the coke; this gives a satisfactory yield of coke, while, at the same time, practically all the volatile-producing oil or tar has been removed and the coke thereby rendered smokeless. Using compartments of suitable width, the coke is uniform in structure and has sufficient strength to permit sizing and handling. The specific gravity is somewhat less than that of hard coke, but not enough to be a practical objection. The breeze and fines burn satisfactorily, either by themselves or with the coarse sizes; in fact, the behavior in the firebox, in that respect, is quite similar to that of bituminous coal. It ignites readily, the fire is easily controlled and successfully banked for 8 to 10 hours in house furnaces during severe winter weather. It burns with a short, bright, clear blaze, and is clean to handle and fire.

An 8-hour test of the semi-coke made from three different kinds of coal was made on a switch engine in one of the large railroad yards in Chicago. The coals were Franklin County, Illinois, Indiana Vein No. 5 from north of Terre Haute, and Indiana Vein No. 5 from Knox County. In clearing up the pile from which the tender load was taken, all the fine stuff was gathered up with the coarse, so that there was a large percentage of it in the tender load, which, in the proportion of coarse to fine, resembled mine-run coal.

There was a light coal fire in the locomotive and on this the semi-coke was started. This fuel steamed rapidly from the start and made no smoke throughout the test. The amount of cinders thrown from the stack with a heavy exhaust was but a small proportion of the amount coming when using bituminous coal. The semi-coke steamed fast enough to make it unnecessary to use the steam blower when the exhaust was off, as is done to lessen the smoke when bituminous coal is used; this effects a substantial saving of fuel. The engine did its regular yard work for about 4 hours, the crew being changed at the third hour. By this time a thin clinker had formed which, however, was readily removed during the noon hour. Another thin clinker was formed and removed during the afternoon, but some coal, of which there was a small amount at the bottom of the tender, had been fired on top of the semi-coke before this happened.

The engineer of tests of the railroad stated that this clinkering probably resulted from the mixing of semi-coke made from three different kinds of coal, and from the excessive amount of fine stuff. Carl Scholz, who was on the engine during a considerable part of the test, was of the same opinion; and they agreed that the semi-coke had satisfactorily shown its adaptability for locomotive use without material change in the firebox. The semi-coke was entirely new to both firemen.

In regular practice, a semi-coke made from one kind of coal will clinker less than the coal from which it is made. This is because the semi-coke burns without permitting the lumps to break down or melt; there is, therefore, a better circulation of air through the fire bed than with coal. Ordinarily, also, there would be a great deal less fine stuff than was in this tender load. In a plant equipped entirely with casting-boxes, the plant run of semi-coke would contain only a small percentage of fine stuff; from his observation in our experimental plant, Mr. Garland estimates this at less than 10 per cent.

Volatile Products of Distillation

In the operation of the experimental oven it was demonstrated that it would not be possible to use a brick wall between the side flues and the containers, and at the same time make a practically complete recovery of the oil and gas in the coal. This was partly due to the small amount of gas—½ to 1 cu.ft. per pound of coal—obtained in the low-temperature process, as compared with 5 to 6 cu.ft. in the high-temperature process. A small air leakage, such as exists in the high-temperature ovens, would therefore produce disastrous results. In the experimental oven the use of plain brick instead of special interlocking brick increased the leakage materially, although special precaution was taken in laying up the brick and in coating the interior of the oven with special low-temperature cement.

The quantitative determination of gas and tar was therefore impossible with this oven. These factors, however, have been demonstrated repeatedly, not only by Professor Parr, for practically every coal mined in the State of Illinois, but also by numerous others. The curves of Fig. 1 show the relation between the coking temperature and the tar produced, in gallons per ton, for a coal containing approximately 30 per cent. of volatile matter. These curves are based on experiments made by Lewes, and correspond with the results obtained by Professor Parr. The Illinois and Indiana coals have 35 per cent. or more of volatile hydrocarbons and will therefore produce correspondingly more tar than the 30 per cent. coal illustrated in Fig. 1.

For a commercial oven, a cast-iron retort will be used, which will be lined on the flue side with silica brick. This retort is ribbed to prevent warping, and is fixed only at the center, leaving the ends free to expand. Since the temperature within the oven does not exceed 1000 deg. F., this will not only insure a gas-tight construction, but the retort will be considerably more permanent than a brick structure, and will cost less for maintenance than brick retorts of this form.

The light tar produced by the low-temperature process is a liquid having the consistency of heavy cylinder oil. Its significant characteristics, as disclosed by Professor Parr's work, are: First, the large percentage of the light fraction cut at 210 deg. C. (about 12 per cent.); second, the large percentage of the middle fraction (about 52 per cent.) and the high temperature of the tar acids therein; third, the low proportion of pitch (about 30 per cent. as compared with 56 per cent. or more in the heavy high-temperature tar), the low melting point of this pitch, and its low percentage of free carbon.

Taking Franklin County, Illinois, coal as a basis, the results of operation at the experimental plant indicated that the products of low-temperature distillation will be about 77½ per cent. of semi-coke having 18 per cent. volatile combustible matter, and about 25 gal. of light tar and oil per ton of coal. There will also be a small amount of ammonia, but since the nitrogen in the coal, which is the source of the ammonia, does not leave the coal freely until the temperature is considerably above 1000 deg. F., the greater part of the nitrogen remains in the semi-coke; if this product is then made into producer gas in a byproduct plant, a large recovery of the ammonia may be made. Treated in this way, the recovery from Franklin County coal would be about 100 lb. of sulphate of ammonia per ton of coal.

This assertion is based upon data furnished by C. W. Tozer, of London, England, regarding his experiments with a coal closely resembling that of Franklin County. In the high-temperature non-volatile coke plants, the nitrogen is all driven from the coal but only the lesser part of it is recoverable as ammonia, because the temperature of the oven is so high that the greater part of the nitrogen does not combine with hydrogen, or, if such a combination is made at first, it is later broken up before it can be recovered.

Based upon experience at the experimental plant, the heating period required with the casting containers will not exceed 8 hours, and it is probable that this may be reduced. The length of time required depends upon the greatest distance which it is necessary for the heat to travel through the coal. A shorter period could be attained by reducing this distance, but if it is too greatly shortened, the result might not be compensatory, by reason of structural and other considerations.

High- vs. Low-Temperature Distillation

Ample data were secured from the operation of this plant, upon which to base enlarged and perfected designs for a commercial plant, and to furnish a sound basis for estimating the cost of installing and operating it. This has been carefully worked out by Mr. Garland and myself, and the results are attractive as to earning power. Such a plant will cost considerably less than a high-temperature plant of the same capacity, and the products will yield a larger return per ton of coal. Franklin County coal, which has a natural moisture content of about 8½ per cent., will yield 12 to 15 per cent. more semi-coke by the low-temperature process than can be derived from it as hard coke by the high-temperature proces. There will be at least double the amount of tar and oil, and commercial investigations indicate that the value of these products per gallon will be several times as great. The high-temperature process will yield several times as much gas as the low-temperature process, but the surplus gas is always sold at a low price. The high-temperature process also has some advantage in the greater amount of ammonia produced, but this is more than offset by other considerations. The opportunities for commercial development of the low-temperature process seem to be great; it is not visionary to predict the substitution of semi-coke, in the central and western states, for a large part of the anthracite and so-called smokeless coals which now come into this territory, by rail or lake.

Many are doubtless well informed as to the large

number of valuable sub-products which may be derived from light tar and oil, and the rapidity with which this chemical industry is now developing in the United States. Dr. David T. Day is authority for the statement that the cracking process for deriving motor fuel from mineral oils has reached a stage of development indicating that it is possible, in this way, to secure nearly 20 gal. of gasoline, or motor fuel of the same value, per ton of Franklin County or similar coal.

Who's Who In Coal Mining

Clarence W. Watson

Two talents possessed by Clarence W. Watson, of Fairmont, W. Va., Chairman of the Board of Directors of the Consolidation Coal Co., which have contributed materially toward making him a successful coal operator and which have been potent factors in helping him to achieve his position in the business world are his genius for organization and his constructive ability, combined with sound judgment and broad vision.

A man of strong mentality, "C. W.," as he is familiarly known by his associates, has surrounded himself in his

LIEUT.-COL. CLARENCE W. WATSON

various undertakings with men upon whose ability he could rely; and, being an excellent judge of human nature, he has rarely made mistakes in his selections. But the chief factor in the success of this well known builder of industries is his integrity. "His word is as good as his bond." That is the way he is regarded not only throughout West Virginia, but in the financial centers of New York, Baltimore and Richmond; and it is this reputation for integrity and reliability which has enabled him to play such an important part in the development of West Virginia's coal and other resources.

The Government was not slow to recognize how useful a man of Mr. Watson's ability would be in connection with many of the large projects undertaken by the War Department, and his tender of his services was promptly accepted. Commissioned as a Lieutenant Colonel in the Procurement Division of the Ordnance Department, many important tasks were assigned to the West Virginia coal man, among them the Neville Island project of the Government. A few weeks ago Colonel Watson was assigned to service over seas, where his ability as an organizer and executive will be much in demand.

In the short span of fifty-four years, Clarence Watson has with the magic wand of organization transformed many sections of the State of West Virginia from sparsely settled hamlets into thriving, prosperous communities; has linked up cities with a network of interurban railways and has given thousands of men employment in the coal mines he has established in four states.

The youngest of three brothers—all of whom are successful business men—C. E. Watson was educated in the public schools of Fairmont and in the Fairmont Normal School. Of modest demeanor, almost to the point of diffidence, Watson is a man of action rather than of words, a thinker rather than a speaker, traits by which he comes naturally since his father, the late James Otis Watson, was a man of few words. The elder Watson was a sturdy pioneer in the state's development, and that his sons have succeeded in carrying on the development work inaugurated by him is attested to by the Consolidation Coal Co., one of the largest concerns of its kind.

The Consolidation company, as it is well known, is only the outgrowth of the Fairmont Coal Co., which was organized by C. W. Watson, Jere H. Wheelwright and others. Aiding in the formation of the Consolidation company, which acquired mines in four states—West Virginia, Maryland, Kentucky and Pennsylvania—Watson became the head of that great concern and remained as such until his election as a member of the United States Senate in 1911, when he retired as president of the company but was made chairman of the board. Upon his retirement from the Senate in 1913 he devoted much attention to the organization of the Elkhorn Fuel Corporation and other companies for the development of the Kentucky coal fields in conjunction with the late John C. Mayo.

Of late years, outside of his business hours, Clarence Watson has devoted much attention to the raising of fine live stock and finds in that his recreation. It might be said, however, that he derives more unalloyed enjoyment from a good game of baseball than anything else.

At the outbreak of the war in 1914 Mr. Watson was touring Germany with members of his family in an automobile, and the party had many trying experiences. Now in France directing the production of materials and in massing them for the use of the United States and its Allies, it would be strange indeed if through the victory of American arms Colonel Watson were able to again visit Germany, as part of a victorious army.

Largely because of Clarence Watson's ability as a business man and because of a feeling that a man of his caliber was needed in the councils of the nation, not only to aid in dealing with present war problems but with the many questions which will arise in the period of readjustment after the war, the Democrats of the state nominated him as their candidate for United States Senator, although both before and since his nomination he has given his entire time to the Government.

Would Replace Coal by Peat Fuel

In an address made before the American Peat Society at its annual meeting held in New York City recently, Prof. C. C. Osbon, of the United States Geological Survey, declared that, because of the shortage of coal, the public might be ready to consider seriously the use of peat in the hope that it would prevent a recurrence, in some localities, of the suffering caused by inadequate fuel supplies. He said that the shortage of coal in many European countries since the beginning of the war is being supplied in part by the increased use of this material, and there is no reason why the United States should not utilize its vast deposits of this fuel.

Dr. Osbon spoke on "Peat Possibilities from the Government Viewpoint," confining himself to the uses of peat as fertilizer and fuel. The total quantity of peat marketed in the United States in 1917, the record year in the peat industry, was 97,363 short tons, and the total amount produced since peat was first utilized has been 466,020 tons. In Europe between 15,000,000 and 20,000,000 tons of peat are produced and consumed annually in generating heat and power. In the United States coal, in normal times, is so abundant and, at all times, is so efficient, readily prepared and transported that only small quantities of peat fuel have been produced and the interest shown in the development of the industry has largely been scientific and experimental. However, in recent years the increasing cost of producing coal and the failure of the output to keep pace with the ever-expanding demand have led to a general advance in price.

Use of Peat Would Release Railroad Cars

Professor Osbon declared that the preparation and storage of peat fuel would not only increase the local fuel supply and in many communities prevent a recurrence of the suffering caused by a coal shortage, but it would release railroad cars that are vitally needed for other purposes during the war. It may be used locally in some states during economic and industrial crises, and in some sections, notably New England, it is believed that peat could successfully compete with other fuels for both domestic and industrial use after the war.

He said that the failure in past years in this country to produce peat fuel on a commercial scale was not due to a lack of market, but to the lack of sufficient capital, to the inexperience of operators, to the failure to recognize that peat fuel is inferior to coal, and to preventable engineering errors. Many extravagant claims concerning the fuel value of peat have been made, Professor Osbon declared, but the sooner its inferiority to coal is recognized the better for the peat fuel industry. Over a million dollars have been spent in this country in trying to produce some form of peat fuel equal to coal in heating value, and careful consideration leads him to believe that there are only two forms in which peat fuel can be marketed commercially in the United States. These are as air-dried machine peat blocks and powdered peat.

Air-dried machine peat is suitable for both domestic and industrial purposes. In calorific value a ton of machine peat is equal to about 1.3 tons of wood, 0.5 ton of good bituminous coal and 0.6 ton of anthracite. It is clean to handle and burns freely, yielding an intense heat and producing no soot or other objectionable deposit. For open grates this fuel is nearly ideal. However, the best results for household use could probably be obtained by burning it in a stove with relatively small grate openings and a restricted draft.

For commercial use powdered peat, Professor Osbon said, has many advantages over machine peat as it can be more cheaply prepared and more readily handled. The consumption of peat in a gas producer is perhaps the most effective way of utilizing peat fuel in the generation of heat and power, for peat that is to be used in this way does not need to be so carefully prepared nor so thoroughly dried as peat that is to be consumed for domestic purposes or under steam boilers.

Analyses of the peats of the United States, Professor Osbon said, show that they are rich in available nitrogen, as much as 70 to 85 per cent. of the whole nitrogen content being of that character. The fixed nitrogen in some peats amounts to more than 2 per cent. of their dry weight, and gas-producing byproduct plants operated with peat could recover this nitrogen in the form of ammonium sulphate. The crushed peat is fed into the furnace of a gas producer in which combustion is regulated by steam and hot air. The peat burns at the bottom of the feed shaft, and, reacting upon the steam, forms water gas and ammonia. These gases are next cleansed of tar by means of a scrubber and are subjected to a fine shower of sulphuric acid, which converts the ammonia into ammonium sulphate and purifies the water gas. After being cooled the water gas may be used under steam boilers, in internal-combustion engines, and for other purposes. It is said that in Italy peat containing 2.5 per cent. of combined nitrogen, when treated by this process, yielded 170 lb. of ammonium sulphate per ton.

Shortage of Coal in New Zealand

There has been a shortage in the coal supply in New Zealand for the past year for two reasons—a decrease in the production of the local mines and also in imports from Australia, according to a recent *Consular Report.* During 1917 the mines produced but 2,068,419 tons as against 2,257,135 tons for 1916, and the imports for 1917 amounted to 597 tons as compared with 293,291,-556 tons during 1916, and 518,000 tons during 1914.

The loss in production was largely due to the decreased output of the miners, since in 1916 they produced on an average of 750 tons per miner, while in 1917 they produced but 715 tons per miner. During the first six months of 1918 the combined importations and coal mined in this country amounted to 1,084,719 tons as compared with 1,083,461 tons for the same period in 1917, while stocks on hand on April 30, 1918, amounted to 151,866 tons as compared with 216,987 tons on July 31, 1917. This shortage of coal has had a tendency to slow down some of the industries in the country, and is threatening the railways, street car, and electric-light plants.

Exports from the United States to Latin America in 1918 were ten times as much as in 1898, and three times as much as in 1910, while coffee, cocoa, rubber, hides, copper, wool, nitrates and bananas, the principal articles imported from Latin America, show marked increase in quantities and increased prices since 1914.

Increasing Coal Mine Efficiency—III

By CHARLES E. STUART
United States Fuel Administration, Washington, D. C.

SYNOPSIS—*A lack of power capacity is often blamed for low voltage at the point of power application. This is seldom the root of the difficulty. Increased voltage may often be secured by connecting together various existing branches of the power line. The mechanical equipment is often in extremely bad condition, and a supposed shortage of power may be rectified by putting engines, boilers and piping in good shape. Electrified mines usually show marked superiority over unelectrified ones.*

VI—Analysis of Mine Power Conditions in Relationship to Production

FIG. 20 is the resultant of a number of tests at different mines and illustrates in excellent manner the possibility of improving the voltage of the average mine by other means than through the purchase and installation of additional large quantities of copper. The improvement as indicated between curve

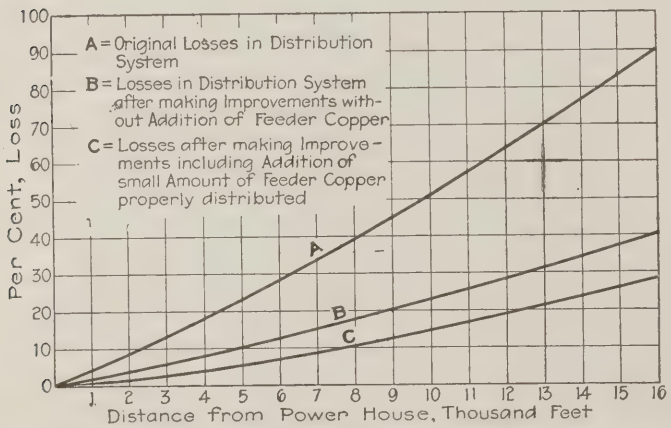

FIG. 20. THE POSSIBILITIES OF IMPROVING THE VOLTAGE WITHOUT EXCESSIVE ADDITIONS OF COPPER

A and curve *B* has been brought about not only by taking full advantage of all copper already placed, but in addition by improving connections of all kinds. The track bonding was perfected. In a word, conditions as represented by curve *B* were as nearly perfect as practicable without additional copper.

Between curve *B* and curve *C* there is represented an improvement resulting from the installation of feeder copper. A comparatively small amount of copper was necessary to obtain this improvement. That which was applied, however, was so placed as to balance the system and to place good voltage at points where conditions were most severe, rather than carry the copper transmission to those places that are seldom used.

Fig. 21 represents voltage and amperage readings on trips going in and out. The condition of the circuit is well indicated. The test deriving this information is simple and can be readily run by a capable mine electrician with the equipment of instruments which it is criminal negligence for any mine to be without.

The proper application and distribution of copper, while not difficult, is a matter for careful consideration, analysis and test. Fig. 22 indicates the location and capacity of trolley line and feeder copper as well as electrical equipment. Analysis of this layout develops the following simple measures, of such nature as to operate the copper and rail to maximum advantage under the conditions existing.

Referring to this sketch, it would be recommended that both 4-0 wires which connect the substation with point *V* should be carefully connected to both trolleys going into the mine entrance—that is, both the trolley on the empty side and on the loaded side. Points *J* and *H* should be connected with a 4-0 line; *S* and *U* should be connected with a 4-0 line; *D* and *T* should be connected. .The following connections should also be made: *P* should be connected with *Q*, *M* with *N*, and *K* with *L*.

In some of the foregoing instances the workings will have to progress a little farther than they are at present, but the advantage of making such connections will be readily seen; and it will be apparent that by means of these connections the utility of the copper now in use throughout the mine will be greatly increased.

As a general proposition a mine does not take full advantage of either its copper or its rail. As a result, copper that is unnecessary is frequently purchased. Conversely, the motors often operate on a lower voltage than is necessary with the copper and rail already installed.

A usual source of power and voltage loss in the average mine is at the bonds. Fig. 23 shows a group of readings taken at random. The record is a good one. The average of a well-bonded track will show a bond resistance of 8 ft. of equivalent rail, and 5 ft. is regarded as an excellent showing. Higher readings may be due to various causes, such as loose terminals and the like. Thus, in the placing of bonds the greatest care should be exercised in order to see that there is no grease or dirt either in the hole or on the bond at the time of insertion. Care should be taken that the fit be tight.

Frequently I have found only one side of the track bonded. More often there is insufficient cross-bonding and almost invariably there are loose terminals. Every fifth rail should be cross-bonded. A loose bond closely approximates a broken connection. Every mine should be equipped with a bond-testing device.

Remember always that the effects of a loose connection, a badly burned switch contact or a grounded wire cannot be overcome by increasing the generating capacity or the installation of additional feeder copper. The parallel of a bad connection is the insertion of a section of ½-in. pipe in a 2-in. line. Do not simply twist a wire connection, but wrap at least 20 turns with No. 10 wire and then solder well. Keep all contacts

of disconnecting switches clean. A corroded or burnt switch, or a contact that is imperfect in any way, is the equivalent of a loose connection.

Extreme low voltage is not necessarily an indication that there is insufficient copper. Such low voltage may occur in entries where the demand is of infrequent occurrence and of short duration. In such cases it would readily become a direct waste of money to attempt to build up the voltage. On the other hand, at those points where the demand is steady, as in the main entries, or where there is a steady pumping, fan or cutting machine load, the voltage should not be allowed to drop below the rated minimum for which the machines were purchased and which minimum is standard with respect to all makes of motors.

It is the rule where there is frequent armature burnout, or in fact where any class of repairs appears to be too frequently necessary, to blame or disqualify the equipment. As a matter of fact, in 99 cases out of each 100 the fault does not lie here. Frequent burnout or excessive repair costs of any kind, which should stand out in a properly developed cost sheet, are an indication of neglect of equipment or of equipment operated under unfavorable conditions. If a locomotive is specified as to weight and motors for the load which it is to handle, if the power conditions are approximately those under which the locomotive is purchased to operate, and if the track conditions are reasonably good, the repair cost will rarely attract attention.

But let it be borne in mind that the actual cost of repairs represents only a small portion of the total cost. The interruptions to service, the loss of time while the repair is being made and the demoralization incident to the interruptions are the real considerations.

Bad power conditions mean the following: First, an actual loss of power and corresponding wastage of fuel in a greater proportion than the actual voltage drop. Second, in a mine where, for instance, there is a 25 per cent. voltage drop, and where the station appears fully loaded, that this station is actually loaded up, not as a result of the work being done, but because, practically speaking, all over 65 per cent. of the demand represents a direct wastage of energy and a corresponding reduction of capacity. Third, bad power conditions, as stated above, mean frequent burnouts and corresponding repair cost. Fourth, there is further entailed interruption to service with corresponding reduction in output. Fifth, finally, and most important of all, is the reduction in the speed and power of the entire equipment of the mine. This may mean that four pumps are doing the work that three should do, or that four cutting machines are doing the work that should be performed by three, or that four locomotives are doing the work of three; in fact, there has often followed an even greater reduction than this in operating efficiency.

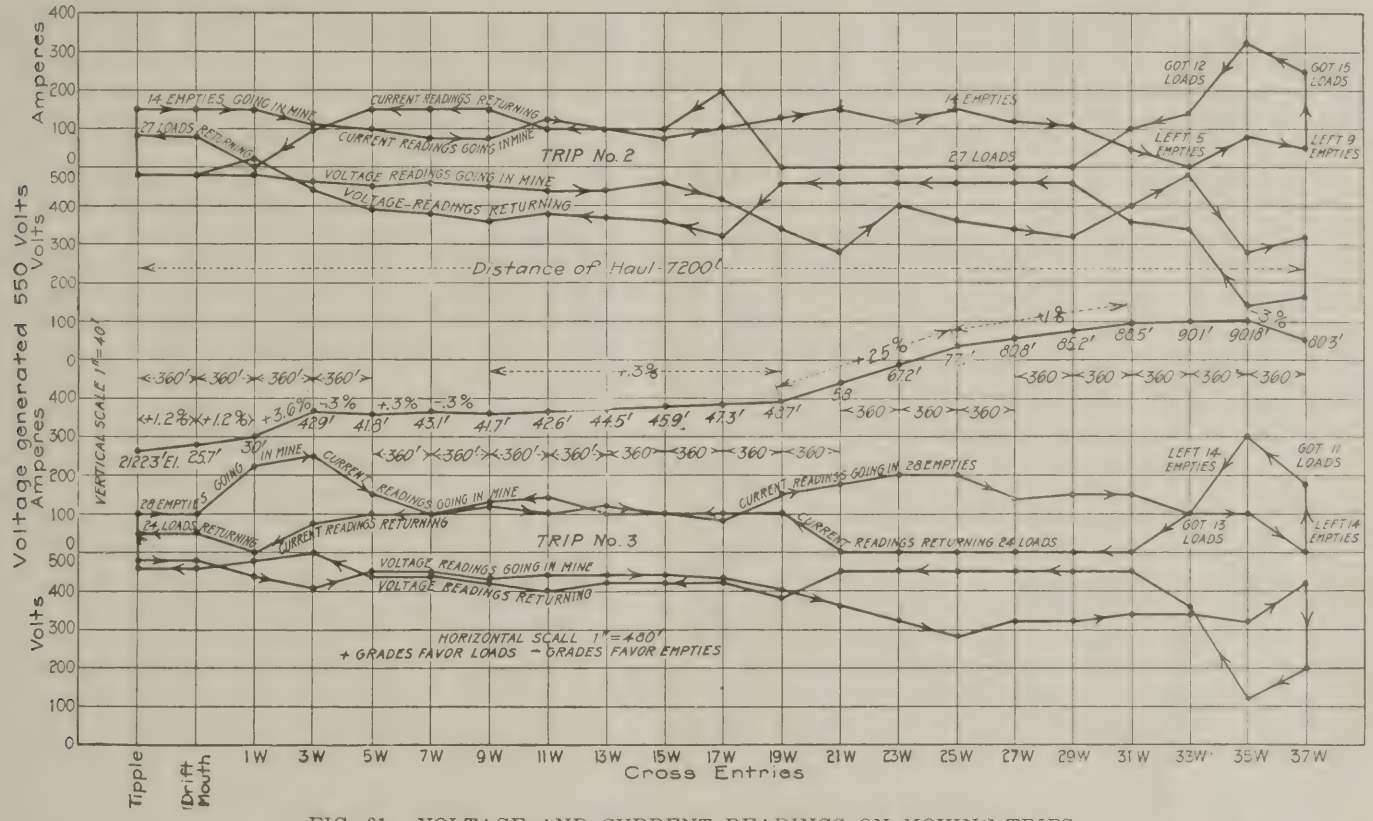

FIG. 21. VOLTAGE AND CURRENT READINGS ON MOVING TRIPS

VII—Track Conditions in Relationship to Production

The trackage of a mine and the operating equipment in general may be readily compared with that of a railroad. In fact a parallel may be drawn at nearly every point. It is possible to operate the main haulage system on a rough schedule. The method of picking up cars is identical. The wrecks and interruptions to service arising from badly maintained equipment and other mismanagement that have rendered many railroads unprofitable have likewise thrown many mines into the hands of receivers and prevented other mines from making money.

The excessive grades, which in the case of a railroad cut down train length and necessitate an increase of locomotive power beyond reason, have forced identically similar burdens on the mine operator. Poor roadbeds and badly maintained trackage such as have reduced the running time of railroads and rendered their maintenance excessive, find their parallel in the mine. A well-laid track, rails of proper weight or if this is out of the question at least properly ballasted and

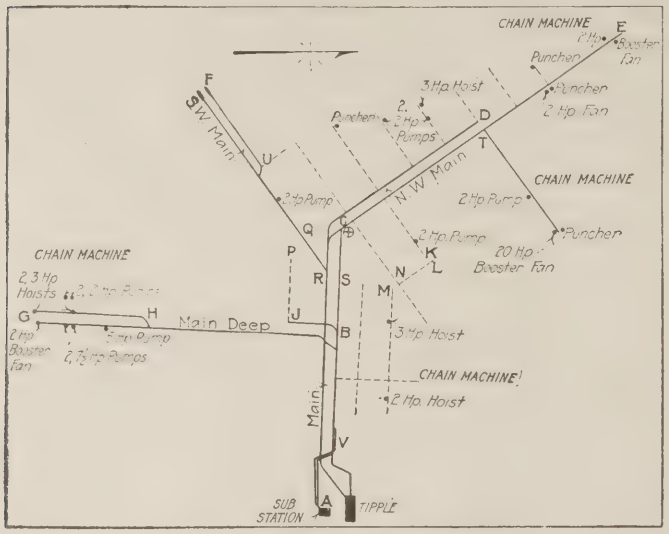

FIG. 22. DIAGRAM OF THE COPPER CONDUCTOR IN A CERTAIN MINE

properly laid, is one of the best investments that a mine owner can make.

In past years it has been the complaint that many of the old Pennsylvania, Ohio and Illinois mines could not be profitably operated on account of the long haul. The deduction is an incorrect one. There hardly exists in this country a mine where the area of development is such as would make the haulage system the determining factor with respect to economical operation.

A properly laid track kept in good repair means an increased production with a decreased cost per ton of coal mined. The reasons for this are clear; however, they may be stated as follows: There results a speeding up of the entire haulage equipment; decreased maintenance cost of locomotives and cars—bumpy track causes rapid deterioration of all rolling stock; wrecks are practically eliminated; rails not properly ballasted or maintained rapidly lose shape not only at the joints, but along the entire length.

VIII—Condition of Generating Plant

If you generate your own power, what is the condition of your engines and boilers? Will indicating engines derive such a curve as that shown in Fig. 24? I have observed and helped to make many engine tests at mines. Cards such as those shown in Fig. 24 are by no means exceptional.

I recently observed the investigation of a power plant of a mine which in most respects is well operated. Seven 150-hp. boilers were feeding three 200-kw. engine-driven generating sets. Using a high-grade fuel five firemen were having a hard time maintaining 60 lb. of steam pressure. The operator in question proposed to purchase additional boilers and generating equipment. Acting on the advice of an engineer, he decided not to purchase this equipment but to rebore the engines and reset the valves, cover the steam piping and install a feedwater heater. The scale was removed from the boilers, the tubes thoroughly cleaned and the settings repaired. As a result, four of the boilers and two of the generating sets carried the load readily.

This example may appear extreme; but if the manager of the average operation really thinks it is, let him conduct a test at his own plant. There is no great expense attached to such a trial, and I believe that the results in many instances will be amazing.

IX—Relative Output of Electrified versus Unelectrified Mines

Table V makes a direct comparison between two mines operating in the same coal bed, the one electrically equipped and the other hand-worked. The table shows that the average number of tons produced per day by each man is 3.94 in one case and 2.64 in the other.

TABLE V. COMPARISON BETWEEN AN ELECTRICALLY EQUIPPED AND HAND-WORKED MINE

	Electrified	Unelectrified	Increase Output Electrified Mine Over Unelectrified	
Thickness of seam	8 ft.	8 ft.		
Kind of opening	Shaft	Slope		
Method of mining	Machine	Pick		
Kind of machines	Electric	None		
Method of haulage	Mechanical	Mules		
Men employed, total	402	550		
Miners	234	305		
Inside men	108	120		
Outside men	60	125		
Yearly output in tons	485,806	450,389	Amount	Per Cent.
Output per miner	2,092	1,476	616	42
Output per man, total	1,218	819	399	48
Number of days operating	308	310	....	..
Number of tons per man per day (total)	3.94	2.64	1.30	50
Number of tons per miner per day	6.79	4.7	2.09	45
Kind of haulage { Electric Locomotive	.....		....	..

Thus, there is shown a clear gain of 1.3 tons, or 49 per cent., each day by each man in the electrically equipped mine.

Considering the state in which these two mines are located and giving due consideration to the characteristics of the different seams operated, it is estimated that if all the mines now hand-worked were to be

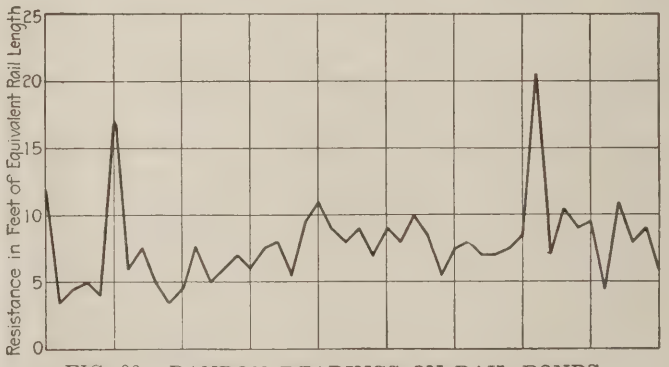

FIG. 23. RANDOM READINGS ON RAIL BONDS

electrically operated, there would be an increase in output of over five million tons; that is to say, the output of the state would be increased by over 25 per cent.

To obtain this increase in output there would be necessary an expenditure of about four million dollars, or approximately 75c. for each ton of increased yearly production. This sum of money in its relationship to the value of the increased production and as measured by the increased requirements of machinery is relatively

small when compared with the cost incident to coal conservation measures which are under way in many sections of the country.

Table VI shows the cost of cutting coal at a certain operation and the estimated cost assuming that electrical equipment were installed. Data gathered since a partial electrification has taken place fully bear out the figures shown. The table is introduced to show the magnitude of the saving made possible through the application of the electric drive.

This table shows that a saving of from 15 to 20c. on each ton produced should be possible when the operation

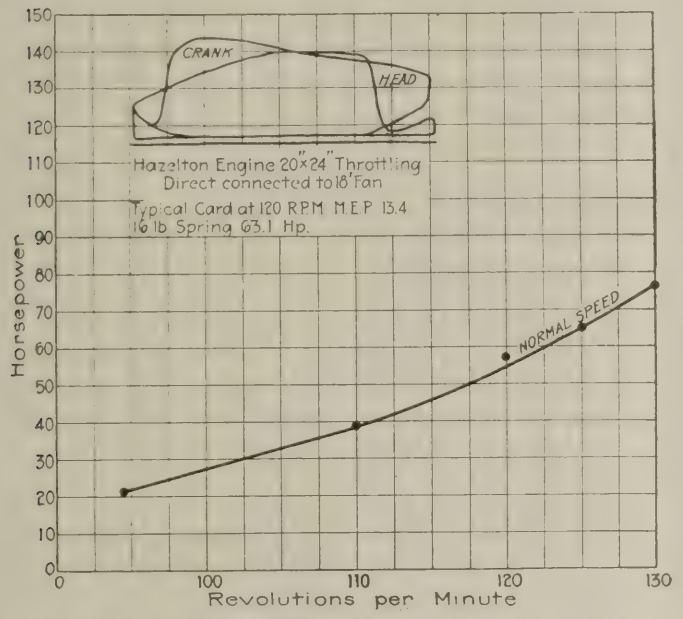

FIG. 24. A NOT EXCEPTIONAL INDICATOR CARD AND POWER CURVE

is completely electrified. In the state where this operation is located, assuming a saving of 15c. per ton, and with a total production from unelectrified mines of 11,000,999 tons, the figure of approximately one year ago, there would accrue a saving in the cost of production in the period of one year of $1,770,000.

These figures, as stated, represent an analysis made

TABLE VI. VARIOUS ITEMS IN PRODUCING COAL UNDER PRESENT UNELECTRIFIED AND UNDER PROPOSED ELECTRIFIED CONDITIONS

Cost of Cutting Coal	Present	Proposed
Labor	17.00c.	5.70c.
Power	4.93	1.12
Total	21.93c.	6.82c.
Cost of Haulage		
Rope	0.25c. labor	3.30
Mule	8.00 power	1.40
Gas engine	1.70 hoist	0.20
Total	9.95c.	11.72c.
Cost of ventilation	0.49	0.63
Cost of dewatering	0.10	0.08
Cost of screening	0.19	0.17
Cost of washing	0.58	0.27
Total	33.24c.	12.87c.
Cost of Pumping		
River pump	0.63	0.39
Cost of operating gin engine larry and tabby	0.23	0.32
(Not total, but cost affected by change in power)	34.10c	13.58c.
Saving		20.52c.

in one state. There is, of course, considerable variation in costs in this state and with respect to the different coal beds operated. Relatively, however, the estimates both as to increased production and decreased cost will hold true as between the different beds. They are also valuable when considering operating conditions in other states.

The mines that remain unelectrified are numerous. In the majority of operations, however, competition has forced electrification, even where decreased cost and increased production have not proved a sufficient incentive. The position of the partially electrified mine can be deduced to some extent from the facts given.

(To be continued)

Direct-Current Armature Trouble

By Frank Huskinson
Trinidad, Colo.

A peculiar case of trouble with a direct-current armature that will be of interest to those having to do with electrical work at the mines, came under my notice recently. The commutator of a 25-hp. direct-current armature was removed for rebuilding. The connections were marked so they could be put back in the same position as they were before. This was a rush job, and the time of testing out the connections was to be eliminated by simply marking the pairs of leads as they were removed from the commutator and then reconnecting them in the same way.

After reconnecting all the leads a bar-to-bar test was made with a milivoltmeter. This test showed all connections O.K. The machine was then assembled and put into service on a pump. The motor seemed to run all right but showed an increase of speed of at least 15 per cent. over what it had run when driving the same pump previously. After running about half an hour, it was noticed that the armature had developed an excessive amount of heat, not confined to any one point but uniform all over the armature and commutator.

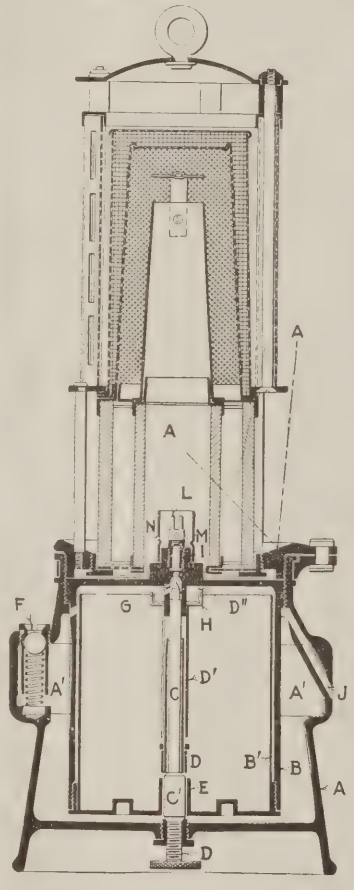
Several tests were then made and all connections as well as the voltage were found to be all right. Several trial runs were made, with the same results as before, the armature and commutator heating up excessively. There seemed to be good commutation as there was practically no sparking of the brushes and the commutator had been undercut.

Finally, I decided to remove the armature and give it another bar-to-bar test with the milivoltmeter. The result was the same as before. I thereupon removed all the leads from the commutator and made a rotation test, with the result that at one point I found that the leads had been interchanged so that the top lead of an adjacent commutator bar had been connected with the top lead of the next bar, and the bottom lead of an adjacent commutator bar was connected with the bottom lead of the next bar. This resulted in the windings being split at this point, putting them in series-multiple instead of straight series.

This armature was connected up to operate in a six-pole machine, and the motor was fitted with six brush holders. It was a compound-wound, 220-volt interpole machine. The action of the milivoltmeter in showing all connections O.K. can readily be explained. The current for testing was taken from a bank of lamps in series with only a small portion of the coils on the armature at a time. If the testing current had been used through one-half of the armature at once, it would have shown up this trouble; but the fact that the armature was for a six-pole machine was not even considered.

Chance Acetylene Safety Lamp*

THE lamp to be described in this article presents many interesting features. Although it is not claimed to have reached the final form for regular mine service, it marks distinct progress. Safety being assumed, the whole question of new lamps turns on the amount of light they will give. As a general indication some figures have been calculated showing that oil lamps will average 7.5, electric lamps 10.7 and the new Chance lamp 37.7 lumens, or about five times the illuminating value of the average oil lamp and 3½ times that of the average electric lamp. This increased lighting capacity will enable the miner to perform his work under conditions conducive to greater efficiency, will tend to reduce the falling of coal and rock, and will undoubtedly lessen the risk of all those accidents which, more or less directly, are the result of ineffective lighting.



A satisfactory acetylene safety lamp should be strong and so constructed as to withstand considerable rough handling without injury or deformation; be simple as to closure and operation; be compact, without projecting parts liable to damage; be reasonably light in weight; give a better light than any alternative type of lamp; be so designed that it can be inclined or even laid on its side for a few moments, without going out or causing excessive production of gas; be self-regulating, so that once lit the regulation of the flame does not require attention; be convenient to use, well balanced, fitted with suitable handle or hook, and preferably about the same weight and dimensions as the lamps ordinarily in use; be capable of detecting inflammable gas and a deficiency of oxygen and generally comply with the usual official tests for safety lamps; generate gas evenly under all ordinary working conditions; not be a source of danger in itself, either by liberation of a dangerous volume of unconsumed acetylene or through starting methane ignitions through the gauze. The cost of maintenance should lie within reasonable limits, having due regard to the fact that effective lighting is a source of profit both to owners and miners.

Advantage of Acetylene Safety Lamp

The Chance acetylene lamp, which is a combination of the American type of Wolf lamp with the Mueseler principle adapted to burn acetylene by means of several ingenious advances upon earlier practice, can be used to detect the presence of firedamp in the mine air and to indicate a deficiency of oxygen. It gives increased illumination and is provided with a special reflector which furnishes sufficient illumination of the roof without tilting the lamp, and allows a proper examination to be made. The upper part follows the construction of the ordinary Wolf-Mueseler lamp, with corrugated shield, double gauzes and Mueseler chimney. The novelties of construction are in the design of the generator and in the use of a special form of burner.

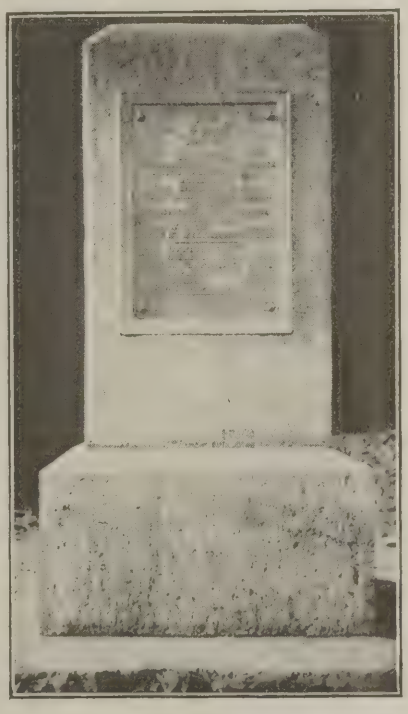
Referring to the accompanying drawing, the outer shell *A* (made of cast aluminum alloy) forms the water vessel. The carbide container consists of the inner cylinders *B*, *B'*, the cover *B* being screwed into the water vessel from above. The cylinder *B* is open at the bottom, which is threaded to fit the cylinder *B'* the latter forming the carbide holder proper. Concentric with these vessels there is the gas-regulating valve *C*, operated by the thumbscrew *D*, which is situated at the base of the lamp. This arrangement permits the raking of the carbide by movement of the valve stem *C'* acting through the water-feed tube *E* at the container base.

The enlargement of the water vessel near its middle, as shown at *A'*, is for the purpose of securing a more uniform head during the working of the lamp. The spring mechanism *F* is a water-filling valve. The gas generated by the upward percolation of water through the upper layers of carbide filters through the felt pad *D''* and into the burner tube *I* by way of the side hole *G* in the valve tube. The valve serves to shut off gas or to lower the flame for methane testing. There is no water valve, the gas control being automatic. When the valve is partly closed, the gas pressure increases, thereby pushing back the water into the outer vessel. If the gas pressure is not sufficiently relieved in this way, water is forced out of the lamp by way of the overflow tubes *J*, of which there are two. The brass tube *I*, shown surrounding the valve stem *C*, and resting on the enlargement *C'* at the base of this stem, is intended to prevent carbide from falling into the water-feed tube when the lamp is being charged. During charging this brass tube slips down into the water-feed tube *E*, and is lifted therefrom by the enlargement *C'* on the valve stem to the position shown when the carbide container is assembled in the water vessel.

DETAILS OF THE CHANCE SAFETY LAMP

The lamp is not dependent for safety on the presence of a rubber or fiber washer at any point. The gas is water-sealed with the addition of the mechanical seal formed by the screw thread at the upper end of the carbide container. The Chance lamp combines the use of the Mueseler chimney with that of the double glass safety lamp. It is thus practically two safety lamps in one. The inner glass chimney is virtually spring-supported, so that falls or blows which might break the outer glass have little or no effect on the inner one.

The air feed is from the lower portion of the bonnet



*From a paper by William Maurice presented at the Nottingham (England) meeting of the Institution of Mining Engineers, Sept. 13, 1918.

downward in the annular space between the glasses and through the bottom horizontal gauze to the flame. The weight of the lamp shown is approximately 4 lb. 2 oz. uncharged, and 5 lb. 4 oz. when charged for a 10-hour shift. It requires a charge of from 7½ to 8 oz. of carbide for 10 to 10½ hours burning time. After 4 hours working it is desirable that the water vessel be refilled, which is accomplished through the spring plunger filling hole. Actually the water vessel contains enough water to run a full shift, but during the later hours the gas pressure drops if more water is not added.

The lamp is of the lead rivet locking type with slip ring. The one lock completely secures both the whole of the generator parts and the internal fittings. Points in favor of the Chance lamp appear to be: Increased illumination, availability as a gas detector, facility afforded for roof inspection, reduced risk of extinction, increased safety, absence of perishable joints and portability and absence of deterioration during storage.

Pioneer Anthracite Mining Engineer

The monument illustrated is a tribute to Archibald Faulkender Law, who was the mining engineer of the first underground anthracite mine. This pioneer operation was opened near Carbondale in June of 1831. Up to that time anthracite had always been obtained by removing the surface; in fact the extensive introduction of stripping in recent years by engineers has been a reversion to the general principles which were accepted almost as final in the earlier days of the industry. According to the record on the stone which was laid in 1901 on the 50th anniversary of the City of Carbondale, Penn., the mine was opened by the Delaware and Hudson Canal Co. The names of John Wurts, president, and John H. Williams, treasurer, appear with those of the officers of the Delaware and Hudson Co., Robert M. Olyphant, president; C. A. Walker, treasurer, and C. C. Rose, superintendent of the coal department.

ERECTED AS A TRIBUTE TO ARCHIBALD F. LAW

Archibald Law was born in Scotland and came to this country in 1830, a year before he opened the Carbondale mine. He came to an extremely sad end. His back was broken in the performance of his duties in the mines and he lingered for five years. The memory of his patience under those years of affliction is still impressed on the minds of his descendants. It may well be said of him that he was bold in enterprise and patient in trial.

Legal Department

SUBSIDENCE OF SURFACE OF LEASED PREMISES.—When a coal lease purports on its face to state the full agreement of the parties, any invention of the lessor to waive the right to support of the surface must be determined by an interpretation of the written contract, without consideration of any extraneous evidence tending to alter, vary or contradict the terms of the writing. The following clause in a lease does not show any waiver of right to have the surface supported: "Said second party [the lessee] to work and mine said coal in a good, careful and workmanlike manner, and not leave unnecessarily any coal which should be and can be mined with safety to the mine and miner, and said second party shall not be required to work low places or rolls which cannot be mined except at a loss." Under the Kansas statute, which requires suit for damages on account of subsidence of the surface to be brought within two years after the right to sue accrues, the two year period commences to run from the time of subsidence, and not from any earlier date when the removal of coal resulting in the subsidence occurred. (Kansas Supreme Court, Walsh vs. Kansas Fuel Co., 169 Pacific Reporter, 219.)

USE OF CONVICT LABOR IN MINES.—A contract for working defendant's mine by convicts provided that the State of Alabama should have entire control of the convicts, who were to be worked under mine foremen and pitbosses to be selected, controlled, and paid by the state; and that the mines should be worked according to directions given by the defendant's mining engineer. Plaintiff, a convict, while working in one of defendant's mines was injured by fall of rock from a mine roof. Under these circumstances, the supreme court of the state holds in the case of Parker vs. Sloss-Sheffield Steel and Iron Co., 76 Southern Reporter, 924, that defendant's engineer was not charged with any duty to inspect the mine during operation to prevent or remedy dangerous conditions of entries and roofs arising from time to time from the operations of the miners in removing coal; and that the defendant cannot be held liable for injury resulting to plaintiff through failure of the state's bosses to discover a dangerous condition of overhanging rock. Liability could not be predicated on any negligence of the defendant's fireboss, in the absence of proof that it was his duty to make inspections for loose rock or to warn miners of its presence; his duty apparently being limited to inspections to discover the presence of explosive gas, and post or give warnings against its presence, and to look out for proper ventilation.

LESSEE'S RIGHT TO REMOVE MACHINERY—A lease of Arkansas coal land contained a clause providing that the "lessees shall have the right to remove all and any machinery placed upon said lands under this contract upon the termination of same." After the lessees had ceased to operate or pay royalties for several years, and had apparently abandoned the lease, the plant was badly damaged by fire. Later the lessors sued to cancel the lease and on cancellation being decreed granted a new lease to a coal company, which took possession of the premises and plant and repaired the machinery. No attempt on the part of the original lessees to recover the machinery was taken for several months after cancellation of the lease. Under these circumstances, the Arkansas Supreme Court holds that the original lessees forfeited all claim to the machinery, saying: "The original lease provided that the lessee might remove the machinery upon the termination of the lease. This did not mean upon the exact moment the lease was terminated, but it did mean that the property should be removed within a reasonable time after the termination of the lease. The facts in this case disclosed that they waited an unreasonable time, and, during that time, permitted the original owners and its lessees to place repairs on the property greater in value than the original property itself." (Heim vs. Brock, 202 Southwestern Reporter, 36.)

Work Sundays to Make Up Tonnage Loss

To offset loss of tonnage more than 70,000 miners in the central Pennsylvania district have agreed to work Sundays in order to keep up production during the epidemic of influenza. Charles O'Neill, the district production manager, reports that some fields have been very seriously hit by the epidemic. Some mines have been forced to close entirely for several days at a time. By working extra hours and on Sunday, it is believed that a considerable portion of the loss will be made up.

"For the week ended Sept. 28, central Pennsylvania produced 1,306,408 tons," says Mr. O'Neill in a report to the Fuel Administration. "Since then we have been losing tonnage, owing to the influenza epidemic. For the week ending Oct. 5, we produced 1,203,942 tons, or a loss of 102,466 tons, compared with the previous week; for the week ending Oct. 12, we produced 1,234,337 tons, or a loss of 72,071 tons, compared with the week of Sept. 28, making a total shortage of 174,337 tons to Oct. 12. The week ending Oct. 19 will show a greater loss."

More than one-tenth of the miners in the Pocahontas district are suffering from influenza, according to R. D. Patterson, the production manager, who has reported to the Fuel Administration for the week ended Oct. 19. He also reports the disease is raging among the employees of the coal-carrying railroads. In addition to the miners, themselves, who are ill, many are kept from work due to cases of influenza in their families.

Middle West Car Situation Satisfactory Says Regional Director Holden

Performance of the railroads in coal loading in the Middle West is all that could be asked, Hale Holden, the regional director for that section, says in a report which follows:

The coal situation in Illinois and Indiana during the month of September was more satisfactory in point of car supply than during the month of August, but much less satisfactory from a production standpoint, as indicated by the following figures, which cover loading in the central zone, or district, and are little more in excess of the actual coal loading in the central western region:

	August	September
Cars loaded, 1918	184,235	172,585
Cars loaded, 1917	150,940	146,302
Increase over previous year	33,293 (22%)	26,283 (18%)

It will be noted less cars were loaded in September than during the previous month due to mines not working Labor Day and many mines being down on the 18-45 registration day, and for the primary a few days later. Conversely, these holidays enabled the railroads to make a better showing as to car supply.

Even with the decreasing loading the Fuel Administration has been pressed to provide markets, and has only been able to do so by arranging for the sale of coal to railroads for movement beyond the normal commercial zone. In order to continue the ratio of increased loading over last year, particularly in Illinois, the Fuel Administration gave consideration the latter part of September to the established zone lines. As a result, the present summer zone line through Wisconsin and Minnesota will be continued as a winter line on all prepared sizes and mine-run. The lower peninsula of Michigan will be held open all winter for Indiana, all grades, and for Illinois screenings.

The accumulation of coal on track in the Chicago district is growing less and is practically down to normal. The state and Cook County organizations of the Fuel Administration have taken hold of the situation vigorously and will undertake to force unloading.

Taking it as a whole, the performance of the railroads during the month of September in this territory in coal loading was all that could be asked by the Fuel Administration. There is the closest coöperation between the railroad officers and the Fuel Administration, and the general organization is working harmoniously and to the best interests. Reports for the five months since April indicate that the commercial coal requirements for Illinois consumption were 48,360 cars per month, or a total of 241,800 cars. We have loaded and handled 290,330, an excess over the requirements of the Fuel Administration of 48,450 cars, or 17 per cent. Figures for September not yet available in detail indicate a still further excess over the requirements.

Treasury Department to Facilitate Handling of Taxes from Mining Companies

With the idea of facilitating the handling of taxes on mining properties, a separate division is to be formed in the Treasury Department. Examiners who are specialists in mining taxation will handle the returns from mining companies. Heretofore, returns from mining companies have given a great deal of trouble, much of which is thought to be due to lack of knowledge of the mining business on the part of examiners. The new plan will be resorted to in an effort to improve that situation.

What One Ton of Coal Will Do

In order that it may be easier to visualize the value of a ton of coal, the Fuel Administration has compiled a number of equivalents. For instance, one ton of coal will make 20,000 cartridges, or 400 bayonets, or 250 helmets, or one-fourth of a ton of steel. It will generate 200 kw.-hr. of electricity. It will carry 15,000 soldiers in one ship two miles at sea. It will move 50 freight cars 50 miles. It will build two tons of shipping. It will make 1400 lb. of coke and the following by-

products: 6200 cu.ft. of gas; 23 lb. of ammonium sulphate; 6 gal. of tar; 2 gal. of benzol; four-tenths of a gallon of toluol, in addition to many drugs, disinfectants and other chemicals. The materials can be gathered and an 8000-ton ship built with 9760 tons of coal. On the other hand, it does not last long when converted into shells being fired against the Germans. In the seven months' defense of Verdun, the French fired 60,000,000 shells, containing 1,800,000 tons of steel. The manufacture and transportation of these shells called for 9,000,000 tons of coal.

Fuel Administration Speakers Urge Large Production on Patriotic Grounds

While the epidemic of influenza has interfered importantly with the plans for stimulating coal production, the Fuel Administration has not called in its speakers. These men, instead of addressing audiences, are spending their time mixing with the men in order to put into circulation the thoughts which otherwise would have reached them from rostrums.

The message which these speakers carry is based on patriotism. The man is urged on patriotic grounds only to make his maximum endeavor. No appeal is based on the incidental fact that his earnings will be increased. No opportunity is lost to point out that six days' full time work every week is the best way a coal miner can back up his comrades at the front.

Holland to Get American Coal

Holland will begin again to take coal from the United States in the near future, it is believed. The War Trade Board has offered to supply her 100,000 tons of coal a month, if she will come for it. If the full amount is taken, however, it will not interfere with the coal budget, which provides 6,000,000 tons for export.

Holland will pay the mine price plus the bunker surcharge and the freight. This will represent a tremendous saving over the price of $36.18, plus a commercial credit of $12.06, which Holland must pay for each ton of German coal. The clearing of the Belgian coast so reduces the danger from submarines to Dutch shipping that it is expected Holland will take its full quota of American coal in the future.

Coal Loading Shows Decrease

Coal loading on railroad cars for the week ended Oct. 19, together with the figures for the corresponding week of 1917, according to the Railroad Administration are as follows:

	1918	1917
Total cars bituminous	195,143	171,041
Total cars anthracite	33,603	41,277
Total cars lignite	3,610	3,976
Grand total cars all coal	232,356	216,294

Increase of 1918 up to and including week ending Oct. 19 over same period of 1917 ..... 730,203 cars

The number of cars loaded with bituminous coal at all mines throughout the country during the week of Oct. 19 showed a decrease compared with the previous week, amounting to 7 per cent. The falling off occurred mostly in the territory east of the Mississippi, and apparently is a direct result of the epidemic of influenza which has been existent in that territory for some time, and seems to have reached the mining regions to an extent sufficient to affect coal loading during the week of the 19th and to a lesser extent during the previous week.

On those roads where the coal loading fell off more than 5 per cent., it was quite usually the fact that the orders for empty cars placed by the mines also fell off to the same extent or greater. The mines were not, however, able to load even up to their expectations, as evidenced by their car orders, a fact which is demonstrated by an extraordinary increase in the number of empty cars left standing over at these mines unloaded from day to day during the week.

The information concerning loading for the succeeding week of the 26th would seem to indicate that conditions have not improved in the coal-loading territory, and a further decline in production must be expected during the week ending Oct. 26.

American Coal Exports in August

Exports of coal, as reported by the Department of Commerce, for August, 1918, and the figures for August, 1917, as finally revised, are as follows:

Coal	August, 1917	August, 1918
Anthracite	678,797	411,804
Bituminous	3,051,628	2,222,187
Exported to:		
Italy	41,519	None
Canada	2,424,668	1,959,017
Panama	72,274	52,831
Mexico	10,389	13,082
Cuba	217,524	105,408
Other West Indies	19,373	12,367
Argentina	35,229	None
Brazil	132,898	46,877
Chile	None	22,720
Uruguay	9,971	7,245
Other countries	87,783	2,640
Coke	107,978	131,751

Retail Prices of Hard and Soft Coal

Retail prices of anthracite and bituminous coal in the principal cities of the country have been ascertained by the Bureau of Labor Statistics of the Department of Labor. The figures for some of the more representative places are as follows:

	January, 1913	January, 1918	July, 1913	July, 1918
Baltimore (2,240 lb.):				
Pennsylvania anthracite—Stove	$7.70	$9.60	$7.24	$10.45
Pennsylvania anthracite—Chestnut	7.93	9.75	7.49	10.55
Boston:				
Pennsylvania anthracite—Stove	8.25	9.85	7.50	10.25
Pennsylvania anthracite—Chestnut	8.25	9.85	7.75	10.25
Chicago:				
Pennsylvania anthracite—Stove	8.00	10.35	7.80	10.90
Pennsylvania anthracite—Chestnut	8.25	10.39	8.05	10.98
Bituminous	4.97	6.67	4.65	6.48
Cincinnati:				
Pennsylvania anthracite—Stove	8.25	9.50	7.50	11.66
Pennsylvania anthracite—Chestnut	8.75	9.50	7.75	...
Bituminous	3.50	6.10	3.38	6.73
Detroit:				
Pennsylvania anthracite—Stove	8.00	9.88	7.45	10.15
Pennsylvania anthracite—Chestnut	8.25	10.08	7.65	10.52
Bituminous	5.20	8.27	5.20	8.18
New York:				
Pennsylvania anthracite—Stove	7.07	9.06	6.66	9.30
Pennsylvania anthracite—Chestnut	7.14	9.08	6.80	9.29
Philadelphia (2,240 lb.):				
Pennsylvania anthracite—Stove	7.16	9.59	6.89	9.85
Pennsylvania anthracite—Chestnut	7.38	9.68	7.14	9.89
St. Louis:				
Pennsylvania anthracite—Stove	8.44	10.43	7.74	11.00
Pennsylvania anthracite—Chestnut	8.68	10.53	7.99	11.25
Bituminous	3.36	5.44	3.04	5.89
San Francisco:				
Bituminous	12.00	13.87	12.00	14.08
Seattle (Zone A):				
Bituminous	7.13	7.87	7.20	9.13
Washington (2,240 lb.):				
Pennsylvania anthracite—Stove	7.50	10.10	7.38	9.96
Pennsylvania anthracite—Chestnut	7.65	10.19	7.53	10.06

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The anthracite settlement has gone one step forward for it has been approved by the Conference of National Labor-Adjusting Agencies, which Conference adopts the regulation defense of the wage increase; namely, that it is necessary to prevent a depletion of mine labor and to avoid dissatisfaction. It declares that the wage scale is given for these reasons only, the mine workers having loyally stood by their contract.

A contract rightfully should require the man accepting it not to leave for other industries while under the contract. The ethics of this matter has never been worked to a finality and perhaps should not be pressed at this time. Furthermore, a dissatisfaction with a contract, such as is here alleged, has not been held in the past a good reason for its discontinuance or revision. As for the contract having been lived up to, that is true of a majority of the men. A large minority, however, has struck frequently to force the hands of the authorities.

Old Anthracite Contract None Too Generous

As a matter of fact the main reason for a change in the contract, namely that the old contract was none too generous, is only implicitly embodied in the statement of the Conference. It seemed reasonable to the labor-adjusting agencies that in view of the high cost of living and the improved status of those engaged in war industries, a better wage should be paid. It is therefore to be granted. It is to be feared that it will do little to reduce labor depletion, and there is a serious danger of its causing difficulty in the bituminous regions, where an increase is expected every time the anthracite region is granted one. Usually the bituminous region has been forehanded and secured its increase first.

Dr. Garfield has refused to consider the demand of the bituminous mine workers, at least at the present time. There is no argument justifying any increase in wage in the bituminous coal industry. The anthracite mine workers said the high wages of bituminous mine workers made an increase in anthracite wages essential. Now the bituminous mine workers say that the increase of the wages of the anthracite mine workers justifies the highly paid bituminous mine workers in seeking a proportionate wage increase.

Plan To Revive Inequitable Differential

To concede what they ask would be to reëstablish the differential in all its pristine inequity, and thus give the anthracite mine workers an excuse for more dissatisfaction and a further increase.

Dr. Garfield is to be congratulated on his decision. His patience with the anthracite claimants was excusable, but patience with the bituminous mine worker would be without excuse. The public is not ready to pay these men an outrageous price for their labors. The Government is little disposed to make the workingmen of America pay any larger wages to these workingmen than it is paying at present.

It is not willing to let a few men in key jobs make the workingmen in less strategic jobs sweat for them. The bituminous coal miner has been squealing about the cost of living, but he has been one of the most persistent boosters of living cost. He is like the man in the crowd, who roughly elbowing his way to the front, angrily demands of the bystanders that they "quit shoving."

It has been estimated that the influenza epidemic has cut the output of anthracite coal between 1,000,000 and 1,200,000 tons a month. When there is sickness, the mines become disorganized. Some who would work are not given the opportunity, and there is general dissatisfaction with the slower run. Moreover, many who come to work are rendered listless either by reason of their own sickness, the sickness of others or fears for themselves. Funerals also occur, keeping men from work. In some places the grave diggers could not perform the large amount of work demanded, and mine workers had to provide for the interment of their own relatives and friends.

Some Greensburgers Who Are Workers

The Fuel Administration has published an interesting account of the performance of the men working for the New Alexandria Coke Co. at Andrico, not far from Greensburg in central Pennsylvania, a mine operated under the supervision of C. L. Clark, a man whom all the members of the Coal Mining Institute of America remember with affectionate good will and whose success is as much due to his amiable personality as to ability as a mining man. Forty-eight men, or 38.3 per cent of the working organization at his mine won honor distinctions for full-time service during July, August and September. Each man worked 78 days during the three months, and the individual tonnage of the 48 men averaged 17 tons a day.

A big celebration will be held at the New Alexandria works this week and personal letters of congratulation and appreciation will be presented the honor roll workers. These letters have been addressed to the men by J. B. Neale, production manager of the United States Fuel Administration. James S. Amend, district production manager, will present the letters and will personally commend each worker for his loyal and patriotic service.

Records of the New Alexandria Coke Co. show it carried an average of 128 men on its pay roll during the three months. Of the forty-eight workers on the honor list 22 are Austrians, 14 Americans and 12 Italians. Each man who retains a record of 100 per cent service during October will receive an industrial service flag. These flags will be displayed by the miners in their homes and will serve as a badge of loyal war-time service.

Austrian Dug and Loaded 323 Tons Each Month

Frank Corent, an Austrian, made the high production record at the New Alexandria. In three months his output totalled 1615 tons. It does one good to commend these New Alexandrians who come from lands with which we are at war and who so admirably sustain us in our efforts. Their loyalty shows that they appreciate America. We could ill afford to intern such men. Good judgment has been shown by the administration in exhibiting resentment toward the subjects of enemy alien countries and toward naturalized citizens from those countries only when they exhibit by their lack of service or by outspoken attacks on the United States a lack of respect for the country of their residence. There are many men among these enemy alien residents who are doubly loyal, loyal for what they have sworn, and loyal again for what they have foresworn.

The miners in central Pennsylvania worked quite generally on Sunday, Oct. 20, to make up for the loss of tonnage due to the influenza, and at last reports were preparing to work again on Sunday, Oct. 27. They are determined to fill their weekly quota whether sickness intervenes or not. As the soldiers are forced to fight on Sunday, the industrial soldiers are backing them by working on that day. It is much to be regretted that such a sacrifice is necessary.

The Spanish influenza still rages in West Virginia. It has not abated to any appreciable extent and few are the coal districts that have escaped it. In the Pocahontas and Tug River districts there are 2100 cases of the epidemic and only 8000 miners are left to maintain the production.

In the New River district a large number of cases are reported, especially in the Loop Creek section and along

the main line of the Chesapeake & Ohio Ry. The production has accordingly been much reduced. The Kanawha and Fairmont districts have also suffered severely. The West Virginia coal association has thought the situation serious enough to put out a general bulletin on the subject.

The question of who is responsible for curtailed coal production has been brought up by the miners in Local No. 1421 at Buckner, Ill., in the form of a resolution which was adopted at a meeting a few nights ago. It declares that, although the Buckner mine was sunk and developed to have a capacity of 4000 tons a day, as much as 5040 tons have been hoisted in a single day, but under existing conditions it is turning out only 2853 tons daily. The reason, it is declared, is lack of cars and underground equipyment. The resolution states that one crew stayed in the mine 6 hours one day and 4 hours on each of three days of last month, and was given only two or three mine cars to fill. A St. Louis newspaper man who made inquiry at the request of the Buckner local found similar complaints at other mines, except at Mines No. 1 and No. 2, of the St. Louis & O'Fallon Coal Co.

Five hundred miners employed at the Security Coal and Mining Co.'s mine at Duquoin, Ill., refused to go to work on Oct. 23 because the Illinois Central R.R. did not provide suitable equipment to convey them to the mines.

There appears to be no finality to the demands of British Columbia mine workers. In the past year and a half, or two years, the wages of coal miners in British Columbia, roughly speaking, have risen 45 per cent., in addition to a 50-cents-a-day war bonus. In other words a man who was receiving $3.65 a day in wages now is getting $5.79 or, if he works an average of 30 days in the month, which most of the overmen do, he gets approximately $174.00 a month. But this is a small wage compared to what some of the best coal miners are making. Yet, on the other hand, it is much more than the wage paid to some of the coal mine inspectors.

The continued advance in living costs, however, has resulted, according to authoritative report, in the decision by the miners to request a further increase and it is understood that they have forwarded to the proper quarters a request that the scale be boosted a further $1 a day. It remains to be seen whether the Fuel Controller will find that this is justified by present living conditions in comparison with those who existed at the time the last raise was allowed. If the men are supported it will mean, no doubt, corresponding addition to the selling price of coal, which went up only a short time ago despite the protests of an indignant public.

Labor-Adjusters Approve Wage Contract

The Conference of National Labor-Adjusting Agencies has authorized the following statement:

"Since the beginning of the war the number of mine workers in the anthracite coal fields has decreased from 180,000 to 144,000, and, under existing conditions, a further depletion, which will seriously affect the output of coal, seems to be inevitable.

"An anthracite wage agreement was entered into last December [November?] by the operators and mine workers, a pledge being made at the time to the Fuel Administration that the contract should continue in force for the duration of the war; but events have made a continued performance of the obligation a real hardship to the mine workers. Yet in spite of this fact the mine workers and operators have adhered to their undertaking and have patiently exerted their energy in order to maintain the required output of coal. They regard the obligation as binding whatever hardships it may entail on them.

"But other considerations than the contract made by the men are involved; for time has revealed conditions that were not anticipated last winter. There has been a movement of men away from the mines to other war industries and a growing feeling of restlessness among the men at the mines. To continue the arrangement of last winter without any readjustment is to disregard a situation that threatens to interfere with the successful prosecution of the war.

"Therefore, in order to ascertain all the facts and to find a remedy for the situation, representative anthracite operators and mine workers have been meeting, in accordance with your [the Department of Labor's] suggestion, with Dr. Garfield and representatives of the Fuel Administration. They have thoroughly considered the figures available in regard to the increase that has occurred in the cost of living since last winter, the relations between wages in the anthracite and bituminous fields, and between anthracite and other war industries.

"As a result of these studies and deliberations, a plan of adjustment designed to check depletion and unrest in the anthracite coal fields has been submitted to this conference for our independent judgment and recommendation in view of the labor situation of the entire country. After careful study of the suggested plan of readjustment and the grounds upon which it is based, we are convinced that the interest of the whole nation compels this readjustment.

Wage Rate From $3.36 To $6.60 per Day

"We, therefore, recommend the readjustment of the anthracite wage scale, as provided in the plan submitted to us, which establishes, in substance, a scale of wages ranging from 42c. per hour for laborers outside of the mine to average earnings for contract miners approximately estimated at $6.60 per day. This scale we have found to be in line with the wages already established by governmental agencies for other industries, and we are convinced that its adoption will act as a stabilizing influence. Without such a readjustment, the vital coal needs of the country are jeopardized. With such readjustment, there should be no further drains on the labor force of the anthracite mines and production should be maintained and, probably, increased.

"Before reaching the conclusion that the readjustment we herein recommend is necessary to meet the national situation, we satisfied ourselves that in no other way can the necessary supply of labor be maintained or stability in the industry be assured. Prior to the European war, labor in the coal fields was largely recruited through immigration. Since 1914 this flow has entirely ceased. Therefore, especially in view of the increased coal need of the country, it is essential that the anthracite industry retain the labor resident in that region.

"The mine workers are fully alive to the country's need for production, and their organizations have carried on an intensive campaign to stimulate output. The efficiency of the workers is attested by the fact that, although there are 36,000 less to do the work now than there were before the war began, the production of coal has been maintained. It is gratifying to know that the mine workers have generously undertaken, for the period of the war, to continue steadily at work even though the observance of religious and other holidays has to be foregone.

Unascertained Factors in Labor Situation

"One matter was made clear in our meetings and we deem it pertinent for the consideration of the Fuel Administration. It appears that there is no scientific knowledge in regard to some of the underlying facts of the anthracite industry, though upon these facts all decisions as to wages and output should ultimately be based.

"Representatives of both mine workers and operators have urged upon us that steps should, at once, be taken so that systematic and authoritative information will be obtainable in the future, in regard to such fundamental questions as comparative earnings, labor turnover, continuity of employment and sufficiency of output. It was agreed that we must create conditions which will assure greater continuity of employment, greater regularity of work, greater quantity of output and that at the same time every safeguard must be provided that will protect the workers in this hazardous industry.

"In a word, the conditions of the industry must be stabilized. Therefore, the attitude of mind of those in the industry in regard to those conditions must be organized. As a necessary prerequisite we must have that basis of knowledge upon which alone we can act wisely and with justice."

EDITORIALS

Peace Without Victory

WE WANT peace because we did not enter the war from any pleasure in fighting. We do not keenly desire victory, for it was not a thirst for glory that made us take up arms. We have no purpose in this war but justice—justice especially for Germany.

And by justice we do not mean that right of "life, liberty and the pursuit of happiness" which the Declaration of Independence, written for well-intentioned people and intended for their governance, said was the right of all the well-intentioned. We, here in America, deny and have long denied the unrestricted rights of "life, liberty and the pursuit of happiness" to such men as are guilty of criminal actions. We do not give them the justice of the well-intentioned, but instead what is known as retributive justice.

That is the justice which for the present we desire for Germany. We seek for an unconditional surrender. If Lincoln was in any way justified in leaving the issue of peace and war to Grant, if Grant was in any measure justified in demanding "unconditional surrender," surely Wilson is today justified in leaving the terms of surrender to Foch; and Foch is authorized by all the dictates of conscience in requiring that the enemy shall admit itself beaten and without any defense but a plea for mercy. What was forced on the knightly Robert E. Lee should be demanded of the unnamed successor or successors of the bestial Ludendorff.

When the sheriff goes to get his man, does he argue with him? Does he promise him just what the jury shall decide as to his guilt? Does he announce to him what the judge shall award him as his deserts? If he did, the sheriff would be considered as violating the law and overstepping the measured limits of his domain. He catches him first, and the law tries him later. He is not suffered to compromise the court.

Of course, the judging and the apprehension of international offenders have not been by law circumscribed, so that we can say the chiefs of the armies and navies may not discuss terms with the offender; but in this case, at least, it would seem well to ask them to avoid doing so. We do not want the administration of justice to be hindered in any way by an agreement that may be used by the ruffianly Hun in such a manner that we may be adjudged as compounding with his villainy.

Economic Losses Arising from High-Ash Coal

DURING the past year or so much complaint has been heard concerning the large amount of slate and bone in the coal shipped by some operating companies. Although much improvement has been made in the matter of clean coal, there is still much room for betterment. Both in transportation and consumption dirty coal entails needless waste and loss.

Of course, the logical place to rid coal of its objectionable impurities is before these impurities have had an opportunity to begin their work; that is, objectionable impurities should never be allowed to travel farther or in any other direction than form the coal face to the gob, a few feet away. Once bone or slate enters a mine car it begins to be a drag and a drain upon transportation, and it never ceases its bad work until it lands upon the ash heap of the ultimate consumer. The farther it travels the more harm it does. The trip from face to gob is the shortest journey possible and consequently the least expensive.

When a coal bed contains high-ash impurity and the miner is paid by the ton, when the cry is constantly for coal and more coal, when miners are scarce, the union vindictive and employers can ill afford to "fire" anyone, the temptation to load out everything that comes down is ever-present. To some it is apparently irresistible. The loader who succumbs to this temptation certainly does not realize the effects of his iniquity. He sees only a chance to clean up his place a few minutes quicker or possibly get out an extra car of coal before quitting time. He does not realize that in loading out bone and slate and similar impurities he is "giving aid and comfort to the enemy."

American miners as a class are unquestionably patriotic. Should you search the country over from Tamaqua to Issaquah it would be difficult to find one who would willfully do aught to aid the Kaiser or any of his infamous brood. None would knowingly or wittingly harbor an enemy agent or spy within his gates—he would like nothing better than the chance to turn such a person over to the proper authorities. The enemy agent is in this country—figuratively speaking—to throw sledge hammers into the gear wheels of American industry. The miner who loads out dirty coal accomplishes this same result. He could scarcely perfrom a greater service for the Hun were he actually in the Kaiser's pay.

Will the Enemy Alien Return?

AFTER the war the enemy aliens are quite likely to return to Europe, those who are favorably disposed toward America as well as those who are not. The best and the worst will go back—the best because their hearts are the largest and they will want to return to restore those they left behind them, and the worst because this country never appealed to them.

It is a question, however, just what will happen to the men who go back. As they are citizens of foreign countries they may be held, and their earnings may be sequestrated in the land of their birth. No great regard will be felt for the sanctity of such property as they have secured by working in the mines of a nation with which their natal country was at war. It is not likely that Germany or Austria will be kindly disposed toward those who thus return. Moreover, their very leaving of their native land was in many cases a violation of the law, for which they may be punished.

It would be a kindness to such men to warn them about the dangers of a return. Their best interest would be served by prudently waiting till they discover just what happens to those who first venture to go home. It is by no means certain that they will not regret the rashness that led them to return to the lands from which they came.

Should there be a military occupation of those countries, perhaps it might be safe to revisit them. But if a revolution occurs, a visit may be anything but prudent; for the United States will not protect aliens, its ægis being held over only its own citizens. It would seem that few would be disposed to leave their jobs and risk their earnings if they only knew that some one would find their loved ones, report their condition faithfully and take charge of the money to be given toward their reëstablishment.

The Red Cross could perform this service for enemy alien laborers in this country, perhaps at a small charge. In fact it could do it better than the emigrant, should he return to do it himself, and meanwhile he would be earning good American wages.

It appears likely that by pointing out the dangers of a return and by providing the emigrant with a means for caring for his family without returning home, most of the enemy alien mine workers would willingly retain residence in America and become desirable citizens. After the war there will be need for them all. With the glories of their native land somewhat abated by the action of our valorous troops, and with a sense of the fair treatment accorded to them in a great war despite the stress of circumstances, they would be prepared to submit themselves to something better than naturalization—the mere letter of nationhood—and accept what is larger, patriotism, which is the nation's very breath and spirit.

Corporational and Personal Cleanliness

THE average mine village is none too cleanly. Some there are which are models in this respect, but in too many cases little attempt is made to keep them clean. What the tenants have to waste they throw on the roadways where a kindly wind may or may not carry it away, if it be light; where animals may devour it, if it be edible; or time convert it into some unobjectional form of matter, if it be perishable.

Some people have tried to blame the street conditions of mine villages for the present influenza epidemic, but if there is any relation between the two it is most indirect. What relation there is may be briefly stated as follows: Tenants who keep and are allowed to keep a noisome street are apt to be careless in the home and to omit these precautions which will prevent the spread of influenza.

The disease largely spreads by reason of personal uncleanliness. If everyone kept his own towel, soap, washrag, pencil, pen and pillowslip; if there had been no promiscuous dipping of individual spoons, knives and forks into a common dish; had knives not been used as forks; if individual knives thus used had not been allowed to slice butter from a common roll; had spitting and sneezing been controlled; had soiled handerkerchiefs been placed in a separate receptacle so that they could be dumped into scalding hot water where the germs in them would not be able to infect the clothes of others; had rooms been properly ventilated day and night, and had all cups and saucers been plunged into scalding water after being used, the germs would have been propagated only with difficulty and probably not in such an intensive way that they could not be resisted by those in good health. Frequent cleansing of the hands would also assist in keeping germs from the mouth. Cleansing the teeth and applying a little antiseptic to the throat and nostrils would give further assurance.

All this seems a terrible waste of time and effort, but who shall say it is unreasonable seeing that the little town of Wishaw, near Punxsutawney, Penn., lost from influenza 65 inhabitants, or one in every six persons. The neighboring town of Du Bois, in a frenzy of fear, is washing its streets with the hose daily and compelling the business men to flush the sidewalks every morning. Excellent measures these, but not nearly as important as that domestic hygiene which is too often neglected.

At the mines of the Lehigh Valley Coal Co., up in the anthracite region, 784 men were laid off at one time. How many of sick there were, in all, it is hard to say. There are probably more in the mines of other companies, for the Lehigh Valley Coal Co. has a splendid nursing and medical system where others have none of the first and less of the second, and have not taught hygiene in season and out of season as has the Lehigh Valley Coal Company.

Just think what the loss of wages must be from such a disturbance as that described. How many towels, pieces of soap, washrags, tooth brushes and glasses might be purchased with the money thus wasted. How many ablutions and scaldings could have been paid for with the money had it been earned! We have yet to learn the cost of disease in decrease of earnings and in loss of life. Some day we will perhaps admire in full measure the old Mosaic laws which kept a people alive when occupying the houses, operating the farms and drinking from the wells of a people who were fast dying out from virulent disease.

With our epidemics we have two mental periods. In one we say we do not know whether the threatened plague will come, therefore why waste time and effort and make ourselves foolish by ridiculous prophylaxis. Then the epidemic steals on us, and we take a new viewpoint. "The evil has reached its height. Those appointed to die are dead. The living are more or less immune, so why worry?"

We shall persist, it is to be feared, in our unprophylactic methods till the next epidemic, though perhaps if we used ordinary methods of self-protection it might never invade our homes. At no time can we train people in hygienic methods as well as we can immediately after an epidemic. We need now to get ready for the return of the disease that is promised for the spring. Had we acted early we could have doubtless prevented the scourge from invading America and spreading from shore to shore.

One great source of danger too often overlooked is the barber. That functionary should be more careful than ever about his ablutions, and when epidemics are rife he should wear a mask for the protection of himself and his patrons. In many towns the barber shaves, and thus infects, a large proportion of the people. A word from the owner of the mine would do wonders for sanitation in which, alas, few barbers have any devoted belief.

Don't Let Up Till He Puts Up Both His Hands

On hearing that the Kaiser had given up his throne and that the surrender of Germany was to be expected any moment, many miners quit work entirely. At other mines men took a day off so that they could celebrate an event which may not occur for several months.

To Your Shovels and Your Picks, Mine Workers, the Hun Is Not Yet Downed!

DISCUSSION BY READERS

Estimating Power in Haulage

Letter—No. 1—Kindly permit me to draw attention to one or two errors, in the reply to an inquiry regarding the manner of estimating the power in mine locomotive haulage, which appeared in *Coal Age*, Sept. 26, p. 615.

The weight of the loaded trip, which is given as 40 tons, is evidently estimated on the weight of coal hauled, instead of on the weight of the loaded cars in the trip, which is $25(3200 + 1200) \div 2000 = 55$ tons. Also, it is quite evident that the fraction, $\frac{1}{16}$, used for determining the tractive effort of the locomotive from its weight, is a typographical error for $\frac{1}{8}$. Permit me to say, however, that even this fraction would be low.

For steel-tired locomotives, the tractive effort may be taken as high as $\frac{1}{4}$ and, for chilled-iron wheels, $\frac{1}{5}$ of the weight resting on the drivers. Making these corrections and assuming the above factor for steel-tired locomotives, gives for the weight of locomotive required as $7\frac{1}{2}$ tons; or, for chilled-iron wheels, say $9\frac{3}{4}$ tons, the power, in the first instance, being 63 hp. and in the second instance 65 hp. But, this horsepower should not be confused with the horsepower rating of the locomotive given by the various manufacturers, in setting the size of motor for locomotives. The characteristics of each motor must be considered.

MANUFACTURER'S METHOD OF ESTIMATING POWER

It is my custom, in making this calculation, to multiply the weight of the loaded trip hauled by the sum of the track and grade resistances, and divide this product by a constant determined by the kind of wheels with which the locomotive is equipped, less the sum of the track and grade resistances.

Thus, taking the sum of these resistances, as given in the reply to this inquiry, as 60 lb. per ton, and the weight of the loaded trip as 55 tons, and using a factor of 500 for steel-tired locomotives, I find, for the required weight of locomotive, in this case

$$W = \frac{55 \times 60}{500 - 60} = 7\tfrac{1}{2} \text{ tons}$$

In like manner, using a factor of 400 when the locomotive is equipped with chilled-iron wheels gives for the required weight on the drivers,

$$W = \frac{55 \times 60}{400 - 60} = 9\tfrac{3}{4} \text{ tons}$$

Now, taking the efficiency of the motors as 90 per cent., and multiplying the weight of the locomotive resting on the drivers by its tractive effort per ton (500 for steel tires and 400 for chilled-iron wheels) and that product by the speed of hauling, in this case, 500 ft. per min., and, finally, dividing the last product by the efficiency of the motors and again by 33,000 gives the required hopsepower. Thus,

Steel tires, $H = \frac{7\frac{1}{2} \times 500 \times 500}{0.90 \times 33{,}000} = 63$ *hp.*

Chilled-iron wheels, $H = \frac{9\frac{3}{4} \times 400 \times 500}{0.90 \times 33{,}000} = 65$ *hp.*

Track resistance depends on type of bearing and the condition of wheels, track and bearings and may vary from 10 to 50 lb. per ton. E. STECK.

Chicago, Ill.

[We thank this correspondent for drawing attention to the inadvertent errors in the reply to the inquiry mentioned. However, we cannot agree with his suggestion to use a smaller factor than $\frac{1}{8}$ of the weight of the locomotive resting on the drivers when determining its tractive effort, in coal mining practice.

MINING CONDITIONS REQUIRE CONSERVATIVE AND SAFE ESTIMATE OF POWER

Coal Age has often drawn attention to the fact that the conditions existing in coal mines are such as to make it advisable to use a factor representing an adhesion of the wheels to the rails sufficiently small to insure that the tractive effort thus found will not be overestimated. Nothing is more exasperating or annoying in mining practice than to find that a locomotive will occasionally fail to haul the estimated load, because of a condition of the track so common in coal mining. It is far better to be on the safe side and underestimate the tractive effort of a locomotive than to err on the other side.—EDITOR.]

Steel Tires vs. Chilled-Iron Wheels

Letter No. 1—I have read with considerable interest and profit the articles presented in *Coal Age*, relating to mining equipment. The character of the equipment used in a mine should be vitally associated with the production of coal, as well as directed toward increasing the safety of mining operations. Much attention and good judgment based on experience must be given the matter of rolling-stock equipment and the maintenance of track in mines.

In this connection, it has occurred to me that much can be said with profit regarding the relative utility of steel tires and chilled cast-iron wheels for mine cars and locomotives. I believe that the cast-iron wheel on mining locomotives is more general than steel wheels or wheels equipped with steel tires. This is probably owing to the fact that the cast-iron wheel is cheaper and, perhaps, more readily obtainable.

In respect to the relative service given by these two types of wheels, it is worthy of note that where comparative tests have been made, the steel wheels, or wheels with steel tires, have been shown to give the most satisfaction. In many instances, it has been found that they have given two, three and four months'

more service under severe conditions of hauling. At times, it has been found that the steel tires last twice as long as a cast-iron wheel. Also, after a steel tire has been worn considerably, it can be turned down to the depth of the blind flange.

In the operations of hauling it is true that the steel wheel has been found to require much less sand than a cast-iron wheel, the amount being about half as much when pulling the same load. Further, a locomotive equipped with wheels having steel tires possesses the advantage that it will pull a much greater load on the same grade, as one equipped with chilled cast-iron wheels. The steel appears to take a hold on the rails, while the cast iron has a tendency to slip, even when pulling a light load. In my experience, I recall an instance where a 10-ton electric locomotive equipped with steel tires pulled a load weighing 10 tons heavier than another locomotive equipped with cast-iron wheels could haul on the same grade.

These facts are extremely interesting to the mine operator, as they show the advantage to be gained by enabling the locomotive to pull a much greater load by reason of this item of its equipment, while consuming the same power and yielding a longer service, which means a great saving in the cost of operation. Even the sand saved is no small item in the mine expense, where the haulage road has some grades requiring its use. W. H. NOONE.

Thomas, W. Va.

The Miner and His Pleasure

Letter No. 6—The letters in the discussion department of *Coal Age* are always interesting to me, but none have given me greater pleasure than those that have been written on this subject, as I am a miner myself and know what it means when one is obliged to forego the pleasure of the few hours he spends on the surface and devote these wholly to the interests of his country.

We have, in our locality, several mines, none of which are the heaviest producers, however, but employ an average of about 200 men. I believe I am safe in saying that 95 per cent. of these men work every day the mines hoist, while 3 per cent. of them may lose a day or two a month and the remaining 2 per cent. perhaps a little more.

MINERS SET ASIDE PLEASURE TILL AFTER THE WAR

Let me say that our miners here enjoy the pleasures of life about as well as any to be found anywhere; but they seem always willing to lay aside their pleasure trips, drunks, etc., until a more convenient season. It may surprise many to learn that about 50 per cent. of the miners in this immediate field own their own homes, and very attractive little homes they are, too.

It was a very common sight, the past summer, to see miners out digging in their war gardens, who, heretofore, had been accustomed to spend their evenings automobiling, playing cards, or loafing in the pool rooms and on store fronts. Almost without exception these men have answered the call to duty, and their evenings are now spent at work in the gardens. It is my belief that they derive as much pleasure in this work as when the hours were formerly spent in pleasure. As the season advanced, and the gardens began to take on a productive appearance, there was a sharp rivalry between neighbors, and a pardonable jealousy was often aroused when another garden nearby appeared a little more advanced than one's own. In other words, the gardening scheme was competitive, each striving to outdo his neighbor.

WORK OF MINERS IN FOURTH LIBERTY LOAN

Speaking of automobiling, several of our boys own cars, but not many trips are taken that lose the owner of the car a shift in the mine. As showing the patriotism of our little community, however, I need only mention the way the Fourth Liberty Loan went over the top in a single day's time, in our township, which is one of nine townships in the county. Our population is principally miners, while the adjoining townships are chiefly farmers, retired farmers, merchants, bankers, etc. We have one town of about 2500 inhabitants and six or eight small villages in our township, while another township has a small city of 6000 or 7000, besides villages. In the recent drive our quota was $82,500, while that of the remaining township was $237,000.

When the drive started, Sept. 28, everybody in our township got busy at once, with the result that we went over the top at noon and had an overplus of $10,000 at 6 p.m. that first day, and there were yet several to be solicited. Two days later, Sept. 30, another township was $48,000 behind its quota, and the remainder of the county is $127,000 behind. It is no exaggeration to say that our men have derived much pleasure from the results of this drive in the Fourth Liberty Loan. Everyone is happy.

OBSERVE STRICTLY BAN ON USE OF GASOLINE

Before closing, I want to say a word on the ban on gasoline. Sunday is the only day the miner really has for rest and pleasure; but the announcement of gasless Sundays found our men well content to abide by the ruling. Although our local fuel administrator gave his permission for the use of an automobile where a man had a long distance to walk to church or to his work at the mine, in one or two instances, such a use was hailed by the cry of "slacker," and, it is needless to say, that put an end to the use of autos on gasless Sundays.

No! The feeling here is that we have no time for pleasure as long as our boys are sacrificing their lives on the battlefields of Europe. Our purpose is to produce enough coal to meet all demands and carry the war to a successful issue and freedom and liberty are proclaimed in Berlin. VICTORY.

The Wagon Mine a Menace

Letter No. 3—While I cannot agree with everything said by H. E. Gray, in his letter, *Coal Age*, Aug. 8, p. 282, I am in favor of closing most of the small wagon mines, so many of which have been opened recently and have a tendency to draw miners from their work in larger mines where they would be able to mine and load a much larger amount of coal.

My conviction is that a miner will produce more coal in a day when working in a large mine equipped with up-to-date machinery than he could if employed in a small mine not possessing the same advantages. There are many reasons for this.

Ordinarily the ventilation of these smaller mines is poor, owing to the fact that there is not enough coal in the tract to pay for building and operating a suitable fan, and the mine must depend perhaps wholly on natural ventilation, or that produced by a furnace.

Small Operations Lack Necessary Capital

Again, the usual operator of a small mine has not the capital to install pumps or other suitable means of drainage. Instead, he must employ waterboxes, which afford a poor means of keeping the mine free of water. Anyone familiar with the use of waterboxes knows what a disagreeable task it is, especially in the winter time when one is liable to contract a serious disease if obliged to work all day in wet clothing, to say nothing of walking two or three miles to his home at the close of the day.

Further, the small operator generally employs no particular system of mining. Such is his desire to put out coal and realize on his investment, that he adopts the quickest means of accomplishing this. The majority of small mines are opened and operated on the single-entry system. Rooms are turned off this entry as fast as the place is extended, and what ventilation is provided must pass through these rooms. The result is that the circulation is often blocked by a fall of roof in one or more of the rooms and the men suffer for want of air.

Conditions in respect to timbering and haulage of coal are practically on a par with those just described. Mules are employed on all the roads in the mine. Light iron and even wooden rails are used, resulting in many wrecks and delays and increasing the danger to the workmen.

Modern Equipment Means Greater Production

There is truth in the statement of George Bowker, in his letter of Sept. 5, p. 464, that every ton of coal mined is that much help in winning the war; but he must remember that the miner working in a small mine and producing four or five tons of coal a day would probably be able to mine from ten to twelve tons a day in a large mine equipped with modern machinery and appliances. The difference between the man's actual production and his possible output represents our loss and the Kaiser's again.

Speaking of clean coal, I agree with Mr. Bowker that the small mine compares favorably, in that respect, with the larger mine, except where the former may be working outcrop coal, which is more or less impure and cannot be satisfactorily cleaned, since the coal itself is of a low quality. However, his statement that the small operator visits the working places every day to inspect them and see that the men are working under same conditions is far from the truth. It is the exception where a small operator does not devote all of his time to working in a place by himself or superintending the hoisting and loading of coal at the surface and other matters, which seldom leave him any time for inspecting the working places of his men.

While the majority of so-called "wagon mines" are operated under the conditions I have described, there are a few of these that, while obliged to haul their output from the tipple to the railroad for shipment, do not deserve the same classification as the local wagon mine. Many of the former are equipped with good machinery and work enough men to call for state inspection by the district mine inspector. Let me suggest that any ruling regarding the operation of small mines should discriminate in favor of such as these.

A competent committee should be employed by the Government to look into the matter and decide what mines are being operated to advantage, and should be permitted to continue operations, and what mines should be closed for the period of the war.

Cleaton, Ky. Ostel Bullock.

Transportation of Coal by Canal

Letter No. 4—Last March, there appeared in *Coal Age* [Vol. 13, p. 402] an article by W. W. Wotherspoon, superintendent of public works for the State of New York, regarding the cost of transportation on the New York Barge Canal, the operation of which has been taken over by the Federal Government.

A little later the question of the relative cost of transporting coal by railroad and canal was discussed, in *Coal Age* [Vol. 13, pp. 938, 1075, 1172] by Mr. Wotherspoon and myself, with a view to showing the practicability of utilizing the canal system of the state for that purpose and the ultimate effect on the taxpayers.

Shortly after the Government assumed charge of the canal, Mr. Tomlinson, the operating manager for the Government, wrote a letter to the New York Chamber of Commerce, in which he said:

> The Government has established identical rates for canal and rail service. . . . But business is not being offered to the canal. . . . I am compelled to admit that traffic if not at a standstill is very small in volume. . . . I have contracted for a considerable fleet of large new steel and concrete boats, which will be built in a few months provided material for their construction is forthcoming.

Following this is Mr. Wotherspoon's statement, in the New York Times, June 22, "We have experienced much disappointment in our attempt to influence private capital to form boat lines and engage in the canal business." Again, June 25, Alfred H. Smith, Regional Director for the Government for Eastern Railroads, for the purpose of inducing shippers to use the canal, issued a tariff making the Railroad rates 20 per cent higher than both canal and former railroad rates.

In view of the foregoing statements, it would be interesting to learn the following facts regarding the operation of the canal under Government control:

1. How many boats have been built by private owners, and what is their carrying capacity?
2. How many boats have been built by the Government and what is their capacity?
3. Has the 20 per cent. raise in the railroad rates resulted in private shippers sending their freight by the canal instead of by rail?
4. If private shippers are using the canal, how many through trips of loaded boats were made from Buffalo to Albany only, and what total tonnage did they carry?
5. How many through trips were made from Buffalo to New York, and what was the total tonnage carried?

6. How many empty trips were made between Buffalo and Albany, in both directions?

7. How many empty trips were made betwen New York and Buffalo, in both directions?

8. What has been the average time of trips between Buffalo and Albany, and between Buffalo and New York?

9. What has been the total tonnage, including through and local, carried on the canal proper, between Buffalo and Albany, in both directions?

If *Coal Age* can obtain answers to all or any of these questions, from either Mr. Tomlinson, Mr. Smith or Mr. Wotherspoon, considerable light will be thrown on the subject of whether the canal will prove to be the economic and commercial success that its advocates have prophesied would result. G. W. WILKINS.

Pittsburgh, Penn.

Air-Cylinder Lubrication

Letter No. 1—I have been very much interested in the inquiry on this subject contained in *Coal Age*, Sept. 12, p. 522, and the reply to the same. My interest in this subject is greater owing to the fact that we have experienced, in our plant, the same trouble from the accumulation of a carbon residue in the air cylinder of our compressors. In some instances, the residue has so choked the valves as to interfere with the proper operation of the compressor.

For a long time, we sought to find a proper remedy for this difficulty, which not only caused much trouble and annoyance but was expensive to remove. It would happen that from two to three times a year, it was necessary to take the compressor apart and scrape the residue out. At times, we have put the cylinder in the lathe, for the purpose of cutting away the deposit from the metal.

EMPLOYS A CARBON REMOVER WITH GOOD RESULTS

After awhile, we learned, through a friend in charge of a large plant, of a carbon remover that he was using that had given good results. It was known as the "J & J" carbon remover. My friend had found that it was also very useful in cleaning out the gummy deposit and carbon residue from gas-engine cylinders. The gummy deposit, he explained, came from the use of a lubricating oil that was not adapted to gas-engine practice. The "J & J" carbon remover cleaned out the cylinders and the valves, in every case.

We had been frequently troubled with a residue that formed a coating similar to oyster or clam shell. Upon the recommendation of my friend, I determined to use the carbon remover he named. Instead of taking the cylinder apart and cleaning it, as previously, I simply attached a belt and ran the compressor, injecting some of the carbon remover through the air valves. The result was simply marvelous, as it cleaned the valves and cylinders from the deposit, which gave no further trouble.

Since that time I have recommended the use of this carbon remover to others. We have found that, by using a small quantity of it, occasionally, the cylinder and valves are kept clean and no trouble is experienced in the operation of the machine. I thought that this information would be of interest in connection with the subject discussed and offer it quite gladly.

Travel of Electric Current

Letter No. 6—Kindly permit me to refer to a few of the statements made by correspondents who, in attempting to give their understanding of the question of whether an electric current flows through the body of a conductor or over its surface only, may have confused the matter in the minds of many.

The flow of an electric current in a conductor is a question that should be left to scientists only, as it possesses no practical value for the electrical engineer. For the most part, the statements made by others are prone to give the impression that there are still great unknown mysteries about electricity, which tends to develop a lack of confidence in the work of the practical electrician.

As a matter of fact, there is probably no other branch of engineering in which the basic facts relating to the application of any particular form of energy to the work it is designed to perform is more perfectly known than in the electrical field. I would even say that the electrical engineer is able, in most instances, to work with far greater precision, in designing means for utilizing the power he employs, than most other engineers.

PRACTICAL APPLICATION OF ELECTRICAL POWER

While it is not known what electricity is, and its nature may not be understood completely, this fact does not hinder the utilizing of this form of energy by the practical engineer. Speaking of the flow of current in a conductor, correct and reliable results are obtained by assuming that a direct current flows practically uniformly throughout the entire section of a conductor, whether the latter be magnetic or nonmagnetic. As has been stated, in the use of alternating current there is a tendency of the current to flow near the surface of a conductor, rather than in its interior. This has been spoken of by some as a "condensation of the current at the surface of the conductor," but is more commonly described as "skin effect."

It can be said, with more or less certainty, that the three factors concerned in this characteristic of alternating current are: The frequency of the current; the magnetic quality of the conductor; and its nearness to the return, which apparently exerts an influence beyond itself having a tendency to modify the flow.

However, in his practical work the electrical engineer can safely forget all that scientists have said about the flow of an electric current not being confined to the conductor. Scientists may have good and proper reasons for this assumption. In like manner the practical engineer, with the exception, perhaps, of the electrochemist, may forget that electricity probably flows from negative to positive, or in the opposite direction to what is universally assumed, which is from the positive to the negative element or electrode.

In other words, our highly esteemed Benjamin Franklin, who formulated this long established theory, may have guessed wrong. But the point I wish to emphasize is that these scientific questions should only concern the practical engineer, in as far as they have a bearing on the use he wishes to make of the matter in practice. Otherwise the discussion may do more harm than good by casting doubt on results already accomplished.

Kansas City, Mo. ELECTRICIAN.

INQUIRIES OF GENERAL INTEREST

Working a 22-Deg. Pitch

I am the foreman of a mine here that has been opened in a seam pitching 22 deg. The coal varies from 3 ft. 6 in. to 4 ft. in thickness and is full of spars, rolls and dykes. The coal has been worked thus far by driving dip planes and turning rooms on 60-ft. centers. Owing to the bottom being quite uneven, it is impossible to drive the rooms on sights; but they must follow more or less the contour of the floor, so as to avoid the necessity of brushing the roof to obtain headroom for the cars. The rooms are widened out on the lower side to a width of 20 ft. The coal is cut with a Sullivan iron-clad, electric chain machine.

Formerly, the rooms were widened on the upper side of the track, but this was changed and they were then widened on the lower side, because so much trouble was caused by the rooms cutting through the pillar. In many cases, hardly any pillar was left, and what remained was too hard to get and did not pay. To avoid this trouble, the company decided to change and widen out the rooms on the lower side of the track.

I have been trying to find a way to widen out the face so that the machine can do better work. It is hard to cut the rooms downhill, and there is not sufficient room to square the machine around and "sump in" at the lower corner so as to enable the machine to cut uphill.

The machine cuts in the bottom slate, which is very soft. Indeed, the bottom is so soft that it is necessary to use planks under the machine. Much time is required to unload the machine and "sump in" and then load it again when the cut is finished. The difficulties encountered in working this seam have caused me to wonder if there was not a better method to employ and one that would give less trouble and produce better results.

In studying over the matter, I thought it might be worked on the longwall panel system that I have seen described in books. Neither myself nor any of the men working with me have had any experience in longwall work. The most of our miners are Mexican and Spanish miners and require much care and watching. I shall be glad if *Coal Age* and its readers can give me any suggestions in regard to a better method for working this seam. MINE FOREMAN.

Madrid, N. M.

It is difficult to give a wholly intelligent answer to a question of this kind and suggest a method of working that would be adapted, in every respect, to the conditions described in the inquiry. In order to form a correct judgment, in the mining of any coal seam, it is necessary to be well acquainted with the situation in all its details. Without being on the ground and making a careful survey of the proposition, it is only possible to give, in a very general way, the outlines of a method that would seem to be adapted to suit the conditions described by this correspondent.

In the first place, assuming that the rooms are driven, on 60-ft. centers, off the dip inclines and widened out to 20 ft., as stated, the thickness of the remaining pillar would be 40 ft. It is hard to see how the rooms would cut through this thickness of pillar when widened on the upper side of the track; or how this difficulty would be avoided by widening out below the track.

However, it is stated that, owing to the uneven formation, the rooms have not been driven on sights. In that case, it is easy to understand that adjoining rooms might hole into each other at any time, unless great care was taken to keep them apart and maintain a good thickness of pillar. This, we assume, is the real cause of the rooms cutting through the pillar.

We understand that when the rooms were widened out on the lower side of the track, the difficulty arose of sumping in the machine, at the lower corner, so as to enable it to cut uphill, instead of starting the cut at the roadhead and cutting downhill. Our suggestion, in this respect, is that the rooms should be widened out, as formerly, on the upper side of the track so that the machine can start at the roadhead and cut uphill.

The necessary precaution must then be taken to maintain the full thickness of the pillar. There is no excuse, in good mining, for permitting rooms to hole into each other, especially where pillars are supposed to be left 40 ft. in width. If the rooms are not driven on sights, they should be surveyed at regular intervals and the position of the roads determined closely in order to avoid the trouble mentioned.

Speaking of longwall work in this seam, we would suggest working the seam on a panel system, by driving places off 300-ft. levels, say 100 yd. apart. When these have been driven up a suitable distance, say 75 or 100 yd., the pillar of solid coal between two adjoining places should be cut across at the face. This can be done by driving a crosscut 20 ft. wide directly across the pitch until it intersects the face of the adjoining place.

By this means, a panel of solid coal will be cut out 100 yd. square. This panel can then be worked out on the retreating system. The machine should start to cut the coal at one corner of the crosscut and cut the full width of the panel, or 280 ft. As the coal is cut and loaded, it can be taken along the face to the roadhead where it is lowered to the level or gangway and hauled to the main slope to be hoisted.

This system would have the advantage of giving the machine one continuous cut for a distance equal to the width of the panel which would mean much time saved in loading and unloading the machine, and sumping. As the cut is started from the roadhead in one of the rooms, it will not be necessary to sump in the machine.

We recommend this system of working as being best adapted to the conditions described. No doubt many of our readers who have had practical experience in the working of such seams will be able to give further suggestions that will be helpful.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—What is the breaking strain and safe working load of a good steel hoisting rope $1\frac{3}{8}$ in. in diameter?

Ans.—For a six-strand 19-wire hoisting rope of crucible cast steel, having a diameter $d = 1\frac{3}{8}$ in., the breaking strain is calculated by the formula

$$S = 39d^2 = 39(1\tfrac{3}{8})^2 = 73.73 \text{ tons}$$

The safe working load varies from one-fifth to one-eighth or even one-tenth of the breaking strain, depending on the depth of the shaft, speed of hoisting and importance of the operation. In this case, for a depth of shaft not exceeding 100 yd., the safe permissible load may be taken as one-fifth of the breaking strain, or, say 15 tons.

Ques.—The current of air entering a mine is 32,000 cu.ft. at the inlet and 34,000 cu.ft. at the outlet. What is the cause of the increased quantity?

Ans.—Assuming that the observations have been carefully taken showing an increase of 2000 cu.ft. per min. discharged at the outlet, the cause may be ascribed to an increase in the temperature of the air current after it has passed through the mine workings. Since the increase, in this case, is one-sixteenth of the intake volume, the increase in temperature of the return current will require to be one-sixteenth of the absolute temperature of the intake air. Assuming the intake temperature is 60 deg., or 460 + 60 = 520 deg. absolute, the required increase in temperature would be 520 ÷ 16 = say 33 deg. F.

In other words, if the increase in the return volume is wholly due to the increase in temperature, the return air current must have a temperature, in this case, of 60 + 33 = 93 deg. F., which is not probable in the normal working of a mine. However, the intake temperature may be much lower, say 32 deg. F., while the return temperature will frequently be 65 deg. F., which would easily account for the observed increase in this case.

Another cause for increase in the return current, in a mine, is the generation of gas in the workings. For example, take a mine generating large quantities of gas, and assume an increase of 2000 cu.ft. per min. makes the return volume 34,000 cu.ft. If this increase is all gas the return air must carry (2000 × 100) ÷ 34,000 = say 6 per cent. of gas, which would show a highly dangerous condition in the mine that can hardly be supposed to exist.

Again, in both the blowing and exhaust system of ventilation the pressure on the intake air is always greater than that on the return. This decrease of pressure will cause a slight increase in the return volume. However, ventilating under, say a $2\frac{1}{2}$-in. water gage (2.5 × 5.2 = 13 lb. per sq.ft.), the atmospheric pressure due to 30 in. of barometer being 2160 lb. per sq.ft., the drop of pressure on the return, in this case, would represent only (13 × 100) ÷ 2160 = 0.6 per cent. of the absolute pressure on the air. Hence, for a circulation of 32,000 cu.ft. per min., under a $2\frac{1}{2}$-in. water gage, the increase on the return from this cause would be only 34,000 × 0.006 = 204 cu.ft. per minute.

Therefore, replying to the question asked, it may be assumed that the increase of 2000 cu.ft. in the return volume, in a mine generating no gas, is due largely to an increase of temperature in the mine when the outside temperature is low. Or, the observed increase may be due to all three causes mentioned.

Ques.—It is proposed to work a pump, which it is estimated will require 23 hp. to drive it. Give particulars of size of motor, dimensions of cable, etc., assuming the pump to be 1300 yd. from the dynamo.

Ans.—Allowing for a line drop of 10 per cent. makes the required power of the generator, in this case, 23 ÷ 0.90 = 25.6 hp. Then, estimating on a 500-volt circuit gives a current of

$$C = \frac{746H}{E} = \frac{746 \times 25.6}{500} = 38.2 \text{ amp.}$$

In order to transmit this current, a distance of 1300 yd. and return, allowing a 10 per cent. line drop, will require a copper wire having a sectional area (A), expressed in circular mills,

$$A = \frac{10.8 \times 2(1300 \times 3)38.2}{500 \times 0.10} = 64{,}360 \text{ cir.mil.}$$

Referring to a wire table, it is found that a No. 2 B. & S. gage wire most nearly corresponds to this requirement, the diameter of this wire being 257.6 mils, or slightly exceeding $\frac{1}{4}$ in.

Ques.—Find the size of an engine required to drive a fan to produce 200,000 cu.ft. of air per min., with a 3-in. water gage.

Ans.—In estimating the size of engine required to drive a mine ventilating plant, it is well to allow for the combined efficiency of the fan and engine of, say 60 per cent. The horsepower on the air required to produce this circulation is

$$H = \frac{(200{,}000 \times 5.2 \times 3)}{33{,}000} = 94.45 \text{ hp.}$$

Assuming an efficiency of 60 per cent., the required indicated horsepower of the engine is 94.45 ÷ 0.60 = 157.4 i.hp. Now, estimating on a piston speed of S = 600 ft. per min. and a mean effective pressure in the cylinder of $p = 76$ lb. per sq.in., the required sectional area (a) of the cylinder is

$$a = \frac{33{,}000H}{pS} = \frac{33{,}000 \times 157.4}{76 \times 600} = 114 \text{ sq.in.}$$

The required diameter (d) of the cylinder then is

$$d = \sqrt{\frac{114}{0.7854}} = \text{say } 12 \text{ in.}$$

Assuming a stroke of 18 in., the piston speed being 600 ft. per min., this engine must run at a speed of (600 × 12) ÷ 18 = 400 r.p.m.

COAL AND COKE NEWS

Harrisburg, Penn.

Urgent representations made to United States Senator Boies Penrose at Washington by state officials, and statements by W. J. Richards, president of the Philadelphia & Reading Coal and Iron Co., as to conditions in the anthracite field, have brought about the issuance of the order by the war department canceling the movement of drafted men from Pennsylvania to Camp Greenleaf scheduled for the week beginning Oct. 28. Under the schedule prepared 6740 men would have gone from Pennsylvania to the southern camp. It was impressed upon the army officers that there are many men ill and that drafted men would go from infected homes, while the coal production was being menaced at the same time.

From all parts of the Central Pennsylvania district messages are being received of Sunday work by the miners, who volunteered following the receipt of telegraphic requests for such service. In those districts where no Sunday work was done the men decided to work from nine to ten hours three or five days each week instead of eight hours, and two days at regular hours, so that the output might be increased. Mines in which the epidemic is prevalent worked with reduced numbers of miners, although several districts, notably the Clearfield, near DuBois, portions of Indiana, Jefferson, Clarion and Cambria, were obliged to suspend operations entirely last week.

Hazleton, Penn.

While the daily papers have published figures showing the tonnage loss due to the influenza epidemic, the figures are not official, and no attempt has been made to total the loss in coal due to the disease, which appears to be on the decrease in Southern Schuylkill and moderating in the Hazleton region. The companies are doing all in their power to stamp out the discase. A daily report of every absentee reported "off sick" is made and nursing help given where needed.

Purchasing departments ordering brass valves and other brass goods are now required to furnish a Government affidavit when placing an order, and in this way they obtain permission for the manufacturing people to ship the material needed.

The Lehigh Valley Coal Co. has notified its Drifton shopmen that the recent wage increase will apply to them. Many of these employees were preparing to seek other employment, as they did not believe the new increase would affect them. The company's action will help to retain these men.

When the first Liberty Loan drive was on, John Markle, president of the G. B. Markle Co., authorized a reduction of 50 per cent. in the rental of the company's houses, giving the employees a chance to invest in bonds. In the Fourth Liberty Loan campaign, Mr. Markle authorized the purchase of $500,000 of bonds by the company in addition to the bonds bought by the men. The credit for the sale of the bonds was given to the villages where the Markle Co. employees reside.

Uniontown, Penn.

The fuel production campaign for the Connellsville coal and coke region, which has for its aim the increasing of the average weekly output to 800,000 tons, 50,000 tons above the present maximum, opened this week under most discouraging conditions. Hardly had the campaign gotten under way when a car shortage paralleling that of last winter struck the region. This shortage is not due to a scarcity of cars, but the lack of railroad crews to move them. The condition grew gradually with the influenza epidemic, but did not reach an acute stage until this week, when it caused a virtual paralysis of the transportation systems in this region. Commencing on the Baltimore & Ohio system, the congestion has gradually extended until it has now affected all lines.

While the car situation had not reached the acute stage for the week ended Oct. 19, the weekly production of the region took a drop of 35,266 tons over the previous week. The output in terms of coal was 714,118 tons. Coal shipments aggregated 246,077 tons, while 312,027 tons were manufactured into beehive coke. In his weekly report to Director of Production J. B. Neale, W. L. Byers, manager of production, stated that had the car placements been normal the figures would at least have reached the last high record of Oct. 12, despite the loss of some 600 workmen because of influenza.

The bone-dry liquor order of the state health department is still in effect, but its good results have been nullified by the combination of car shortage and influenza at the plants.

Charleston, W. Va.

There was not as much of a drop in production in the Tug River and Pocahontas districts as might have been expected in view of the fact that there were 2100 cases of influenza in those regions, the decrease being only 394 tons during the week ended Oct. 19, as compared with the previous week—tonnage produced being kept up to 463,151. Tonnage lost from all causes was 588,684. An increasing car shortage cost 17,539 tons in production, while 37,457 tons were lost because of a shortage of labor. No loss, at least no material loss, in the coke output was recorded, the production of coke being 50,627 tons.

The output for the Fairmont district has been reduced by half during the last few weeks. That is not hard to understand when it is said that the car supply, for instance, on Oct. 19 was only 613 cars, on Friday 579 cars, on Thursday 770 cars, and that on all three days only 500 cars have been placed on time. The loss of production in the field the week ending Oct. 19 varied between 33,000 and 47,000 tons a day. On Oct. 19 there were over 4000 men idle and out of 177 mines reporting 53 were shut down. Lack of cars has caused much enforced idleness and of course has seriously interfered with the movement for the increased production of coal.

Mines in the Upper Potomac region, especially in Mineral County, have been hard hit. This has been particularly true at Elk Garden. A telegram from that point to Governor Cornwell this week requesting two doctors and a few nurses stated the situation was serious and that the coal mines had been paralyzed.

Heavy inroads were made on production in the Kanawha region the week ending Oct. 19 through the wider prevalence of influenza, and even at points where there were comparatively few cases fear of the disease tended to keep the men out of the mines, thus making it impossible to secure the capacity output. As a result of such conditions production dropped from 178,000 tons to 148,380 tons. Some idea of just how badly crippled the mines are may be gathered from the fact that only a few weeks ago 217,000 tons were produced. Total hours worked during the week under review were reduced to 4482. There was a greatly augmented shortage of cars, 1029 hours alone being lost from that cause. The labor shortage was responsible for the loss of 733 hours.

Production sagged in the New River district the week of Oct. 19. While in some parts of the district there was a tendency to take advantage of the situation created by the influenza epidemic, nevertheless on Loup Creek and in that part of the district on the main line of the C. & O. sickness kept many men out of the mines. Taking both the New River and Winding Gulf districts there was a decrease of 15 per cent. in production, as compared to the preceding week. This decrease may be attributed solely to the prevalence of influenza and a car shortage on the C. & O. Cars were plentiful on the Virginian Railway.

Birmingham, Ala.

The coal-mining situation in the Birmingham district at present is not as bright as it might be, the influenza epidemic making itself heavily felt throughout the district. In several camps the physicians themselves were stricken with the disease and were unable to attend sick miners. The state health authorities and the Government were applied to for assistance, and physicians have been sent those asking for them.

The production of coal for the week ending Oct. 12 was 382,846 tons, against 409,022 tons for the week ending Oct. 5. Transportation facilities in the district have been good recently, everything considered. Operations at mines throughout the district have been greatly curtailed during the past ten days, and as a consequence, the demands for cars were not so urgent. In other traffic, however, there has been no decrease in the demand for cars. The records show an exceedingly fine business being done by the railroads.

The Woodward Iron Co. is planning extensive improvements to its plant at Bessemer during the coming year, according to rumors in industrial circles and especially at Bessemer, where the improvements will be made. The taking on of H. M. Urban, former superintendent of the byproduct plant of the Tennessee Coal, Iron and Railroad Co. at Fairfield, is declared most significant.

Victoria, B. C.

In view of the discussion as to the production of British Columbia's coal fields this year, and the possibility of the output meeting at least the most pressing demands, both domestic and foreign, it is interesting to give the results of a rough estimate made by a high authority. Up to the end of the month of August the production was 1,821,681 tons, and an estimate of the output of the month of September (the returns being not yet available) is 167,301 tons, making a total of 1,988,982 tons up to the last day of last month. From this must be taken 221,840 tons, which was used in the making of coke. The total coal marketed from this Province for the first three quarters of the year, therefore, would be 1,767,142 tons. At the conservative valuation of $5.50 a ton, this would be $9,719,281. In this period it is estimated that the Crow's Nest Pass Collieries had produced 130,389 and the Canadian Collieries (D) Ltd. 19,196 tons of coke, a total of 149,585, which at a valuation of $9 a ton, equals $1,306,265. So that the value of the coal production of British Columbia may be said to aggregate approximately $11,025,546.

The opening up and development in a small way of coal outcroppings is being given more attention in British Columbia as a result of the increased demand and the higher prices received for coal. One of the most important of these is situated on the Grand Trunk Pacific Ry. not far from the City of Prince Rupert. The Government has assisted in the construction of a road to the property, and the owners and operators are confident that they will be able to take care of the greater part of the domestic demand of Prince Rupert and the adjacent district this winter. Another enterprise of a somewhat similar nature is that of the Osoyoos Coal Co. at Ashnola, nine miles from Princetown, B. C. This has been reopened and the coal will be hauled into Princetown by motor trucks for local use and for shipment by railway to outside markets.

PENNSYLVANIA

Anthracite

Jeddo—The G. B. Markle Coal Co. has installed 30 cots in the Jeddo Casino, which will be used as an emergency hospital for influenza victims.

Tamaqua—The Maryd Coal Co., operators of the Maryd colliery, near Tamaqua, have lost 18 miners by death, due to the influenza.

The Mill Creek Coal Co. has electrified its New Boston colliery, and the same work is now under way at the Shepp mine at Tamaqua, Penn.

Hazleton—M. S. Kemmerer & Co., operators of the Sandy Run colliery, have let the contract for an addition to their breaker.

Bituminous

Waynesburg—A deed was recently recorded here by which W. F. Bute disposed

of a one-half interest in four tracts of land in Green and Monongahela townships, Green County, to W. Harry Brown, for a consideration of $55,211.04.

Uniontown—O. M. Coughenour, of Uniontown, has sold a one-half interest in the coal underlying three tracts of coal land in Green and Monongahela townships, Green County, to W. Harry Brown, of Pittsburgh, for a consideration of $1.

Greensburg—All production records for the Westmoreland district were broken last month, when the mines produced 401,000 tons of coal. The output was 13,000 tons in advance of the previous high mark of the district since the coal production campaign began July 1.

Boswell—The Atlantic Coal Company is abandoning its mine at Boswell, Somerset County, on account of the large number of rolls and faults encountered in the seam. This mine is in what is known as the "E1" seam, the company having previously exhausted the "C1" seam of coal below it.

Homer City—The Homer City Coal Co. is erecting a bathing and dressing house for its miners at its Tearing Run Mine near here. The building will include shower baths, dressing rooms and clothes-drying room. There is also provided a first-aid room and a room for use of the officials.

Fallen Timber—Announcement has been made that M. Hempskie, a coal miner at the local plant of the Fallen Timber Coal Co., recently broke all records for large earnings. A total of 116 tons of coal was mined in two weeks, including 17 yards of main heading, 13 yards of back heading, and four yards of room, for which he was paid $246.28.

Orbisonia—James L. Devveny, broker, reports the sale of the Daugherty mine at Rocky Ridge, Huntingdon County, to Thomas and Roth of Wilkes-Barre. The mine has been operated by Henry M. Kerr, of Philadelphia. The new owners will greatly increase the production by installing new machinery and making a number of improvements.

Uniontown—The Vanderbilt Coal and Coke Co. has taken over the old Clarissa plant of the James Cochran Sons Co. and has resumed operations at the works. Eighty ovens have been reconstructed and a number placed into blast. More will be fired when labor conditions permit. A new tipple has been erected. Forty-four houses at the plant have been repaired. Between 75 and 100 workmen are employed at the plant, of which A. C. Stickel is president and Gaetano Corrado of the same place is treasurer and general manager. What coal is not used at the plant is shipped for by-product purposes.

ILLINOIS

Freeburg—The five mines in the vicinity of Freeburg have been facing a shutdown during the past week for lack of water. The lake and ponds from which they had drawn their supply had about gone dry, and the Government had interdicted the bringing of water from the Okay River at New Athens in tank cars. Rainfall has in a measure relieved the situation.

Williamson—The Mt. Olive and Staunton Coal Co. has offered a reward of $500 each for the bodies dead or alive of the four men who robbed the company's cashier here on Oct. 15 of $14,000, and an additional bonus of $1000 if all are taken together, and 10 per cent. of all or any part of the stolen money that is recovered. Information is to be communicated to B. G. Valentine, Chief of Police of Staunton, Ill. The men are described as dark complexioned, apparently either Italians or Greeks, between the ages of 20 and 25. Three were smooth shaven and wore caps. One had a black mustache and wore a black soft hat. They escaped in a new black automobile.

O'Fallon—Steps are being taken to resume construction work at the O'Fallon mine, which was stopped some time ago on account of financial embarrassment of the promoters, John Hargraves and W. A. Knapp. The property has been taken over by Albert W. Black, John L. Lamont and William S. Fotheringham, of Bay City, Mich., to protect a loan which they made when the sinking of the shaft was begun. Besides the unfinished mine they find themselves with about $70,000 obligations on their hands. Arrangements have been made to compromise the claims with the exception of those of the miners, which will be paid in full. The shaft will be completed at an estimated cost of $200,000. A new pump has been installed and the water is being drawn from the shaft. Two carloads of machinery are on the way. Alex Jeffrey, of Bay City, will be general manager, and Oscar L. Pyle, of O'Fallon, will superintend the construction work.

OREGON

Marshfield—The old Klondyke coal mine of Beaver Hill was opened recently for the first time in twenty years and 160,000 tons of coal was found in the tunnel. The output will go to the Government for fuel in engines used in hauling logs from the Boutin tract of spruce now being cut by the Government, which has a force of 200 men at work building railroads to the mine and to the timber. The Government has contracted for the entire output, and any surplus not used by the engines will be handled by the Fuel Administrator.

WASHINGTON

Chehalis—W. F. West, W. D. Sheldon and Ben Sheldon, owners of the Sheldon Coal Co., have disposed of their interests in the mining property near the town of Coal Creek to Gay & Olson Co., of Tacoma. The property is to be immediately placed on a production basis of 550 tons per day. At present an 8 ft. sub-bituminous vein is being worked. A new slope is to be sunk at once.

Personals

O. P. Chatfield has severed his connection with the Kanawha Central Coal Co. and will hereafter be associated with the Carbon Fuel Co.

W. B. Plank has been transferred from the Bureau of Mines Rescue Station at Urbana, Ill., to take charge of the Bureau of Mines Rescue Station at Birmingham, Ala.

E. T. Twescher has been appointed office manager for the Campbell's Creek Coal Co.'s harbor at Point Pleasant. Mr. Twescher was formerly with the Producers Coal Co. at Cincinnati.

B. E. Geer, of Greenville, S. C., has been appointed fuel administrator for South Carolina. He is a manufacturer of cotton goods. He succeeds **B. B. Gossett**, who has entered the military service.

Jerome Watson, of Neffs, Belmont County, Ohio, has been appointed chief mine inspector for Ohio by the Ohio Industrial Commission, to fill the vacancy caused by the death of L. D. Devore. He has assumed his duties.

J. C. Maguire, formerly construction engineer for the Wilmot Engineering Co., Hazleton, Penn., has entered the service of Wentz & Co. as mechanical engineer. Mr. Maguire will have charge of breaker machinery, a line in which he specialized while with the Wilmot company.

W. D. Tyler has been made acting director of the Bureau of Prices of the Federal Fuel Administration. For the past twelve years, Mr. Tyler has been in charge of the real estate department of the Clinchfield Coal Corporation. He succeeds **E. Q. Trowbridge**, who has entered military service.

Samuel Jones, formerly mine foreman at McIntyre, Penn., for the Jefferson & Clearfield Coal and Iron Co., has resigned his position as mine foreman for the Morrellville Coal Mining Co., Johnstown, Penn., to accept the superintendency of the Union Central Coal Co., Inc., Butler, Penn. Mr. Jones will assume his new duties on Nov. 1.

Richard D. Maize, mine inspector, of the Fifth Bituminous district at Uniontown, Penn., has been granted a leave of absence by the Chief of the Department of Mines of Pennsylvania, to enter the army. Mr. Maize will enter the University of Pittsburgh for intensive training. **Silas C. Hall** of Van Voorhis, has been appointed temporary inspector.

Wade H. Horn, formerly chief engineer of the Raleigh Coal and Coke Co., at Raleigh, W. Va., and at present right-hand man to Frank A. Ray, consulting mining engineer, Columbus, Ohio, has accepted a position with the Wisconsin Steel Co., Benham, Harlan County, Kentucky. The company contemplates the doubling of its present coal output, and Mr. Horn will be in charge of the new construction work.

Obituary

Charles G. Roebling, president of the John A. Roebling's Sons, Co., Trenton, N. J., manufacturer of wire rope for coal mining, died on Oct. 5.

W. H. Christ, a prominent mining engineer and former official of C. M. Dodson & Co. at Beaver Brook, Penn., died at his home in Mahanoy City recently.

Donald B. Earwood, store manager of the Ingram Branch Coal Co., died Oct. 22 of pneumonia, following an attack of influenza, at Beckley, W. Va. Mr. Earwood was sick for only a week.

W. W. Harding, superintendent of the No. 9 works of the United States Coal and Coke Co., died Oct. 22 of influenza. Mr. Harding had been for ten years with the United States company and was one of the most efficient mining men in the region. He was buried at Wilkinsburg, Penn.

J. M. Guthrie, of Indiana, Penn., died Oct. 19 after a short illness of pneumonia. He was the pioneer coal operator of Indiana County and was instrumental in opening the Graceton, Tearing Run and other mines in the county. He was the builder of the first coke ovens in this section. He was aged 87 years.

Frank I. Parker, of the Cutler-Hammer Manufacturing Co., Milwaukee, Wis., died at his home in Milwaukee on Oct. 18, at the age of 36 years. His death was due to pneumonia contracted through Spanish influenza. Mr. Parker was graduated from the University of Wisconsin in June, 1906, and in July became engineer in charge of production in the magnet and clutch department of the Cutler-Hammer company. Since 1911 Mr. Parker has had charge of sales service work on clutch department products. He was made an associate member of the American Institute of Electric Engineers in 1910 and in 1913 became a member. He is survived by his widow and one child.

Industrial News

Columbus, Ohio—The Columbus city government has purchased a coal conveyor for the municipal coal yard from the Columbus Conveyor Co., for $3875.

Cleveland, Ohio—The Lakewood Engineering Co. announces the opening of offices in New York City, at 111 Broadway, in charge of George S. Hedge, district manager. The company specializes in construction plant and industrial haulage.

New York, N. Y.—Morris & Co., of Chicago, Ill., recently placed an order with the Locomotive Pulverized Fuel Co., of New York, for the installation of a complete "Lopulco" system for crushing, drying, pulverizing and burning coal. The equipment is to be installed at the company's steam power plant at Oklahoma City, Okla., and native coals and Texas lignite will be used.

Cleveland, Ohio—The Barber-Greene Co. announces the strengthening of its organization as follows: F. E. Smith, chief engineer, formerly of the Engineering Department of the Stephens-Adamson Manufacturing Co., of the Granby Mining and Smelting Co., and the American Zinc and Chemical Co. George C. Sanford, superintendent, formerly of the Elevator Supplies Co., and of the Otis Elevator Co.

Washington, D. C.—Despite speed at which coal is being produced in this country, and the increasing danger of accidents, there was a reduction of 121 fatalities the first six months of this year as against the same period last year. Figures issued by the Federal Bureau of Mines show that fatalities during the first six months last year totaled 1298. During the same period this year the number dropped to 1177.

Wallace, Idaho—Robert N. Bell, state mine inspector, who recently inspected the Teton Valley Coal property, stated that the development work being carried on will insure hereafter the whole upper Snake River valley against future coal famines and will make coal prices considerably lower in this section. As soon as a ten-mile spur track is completed the mine will be able to supply the entire southeastern section of Idaho.

St. Louis, Mo.—The Walter A. Zelnicker Supply Co. announces the appointment of R. H. Wilson as assistant to the president, with office at St. Louis. Mr. Wilson, who has been with the company for years, latterly as Houston representative, is succeeded there by E. O. Griffin, well known in Southwestern railroad circles for the past twenty years as storekeeper and assistant general manager of the International & Great Northern, and more recently as assistant to the President of the St. Louis Southwestern in charge of purchases.

Toledo, Ohio—Because of the prevalence of the influenza epidemic lake shipments from Ohio and West Virginia have been slightly reduced. This is shown by the record of the tonnage handled by the docks at Toledo. For the week ending Oct. 19 Hocking Valley docks loaded 151,780 tons, as compared with 206,508 tons the previous week, making a total of 4,234,433

tons for the season. The Toledo & Ohio Central docks during the same week loaded 89,000 tons, as compared with 91,000 tons the previous week, making a total of 1,979,000 tons for the season.

Springfield, Ill.—Governor Lowden of Illinois has appointed a mine investigation committee to pass upon proposed amendments to the state mining laws which are to be offered to the next General Assembly. The first meeting was held this week at Springfield, at which Thomas A. Jeremiah, of Williamsville, was chosen chairman and Charles M. Jones, of Marion, secretary. Meetings will be held at intervals and miners and operators will be summoned to give their views on proposed changes in the law. A number of recommendations will be made by the State Mining Board.

Charleston, W. Va.—Casualties in the mines of West Virginia during September reached a total of 37, by far the largest proportion of such deaths being due to falling roof and slate or coal, no less than 20 men meeting their death in such a manner. Mine cars within the mines killed five and a motor one. Two were electrocuted, two died in inside explosions and one was killed by a mining machine. Outside the mines there were only six deaths—four being killed by mine cars, one by a motor and one under the head of miscellaneous. The heaviest death rate was in McDowell County—8. Of the 37 men killed, 24 were Americans and 13 were foreigners.

Columbus, Ohio—A general advisory committee to have charge of production of coal in Ohio has been named by James H. Pritchard, production manager for southern Ohio, and J. J. Roby, production manager for eastern and northern Ohio. These two production managers felt the need of a general committee in order to coördinate the production campaign which is to be started soon. The committee consists of three miners and three operators. For the operators G. C. Weitzell, resident vice president of the Pittsburgh Coal Co.; A. A. Augustus, president of the Cambridge Collieries Co., of Cleveland, and S. H. Robbins, president of the Pittsburgh Vein Operators' Association, Cleveland.

New York, N. Y.—The Anthracite Committee of the Fuel Administration, composed of J. B. Dickson of Dickson & Eddy of this city; S. D. Warriner of the Lehigh Coal and Navigation Co., and W. J. Richards of the Philadelphia and Reading Co., have about completed arrangements governing distribution in the United States and Canada of virtually every ton of domestic anthracite which can be supplied to consumers up to next April. This includes all coal that can be produced between now and then. Since last April the committee has controlled and distributed some 45,000,000 tons of anthracite, in accordance with the allotment as announced by the committee on May 29.

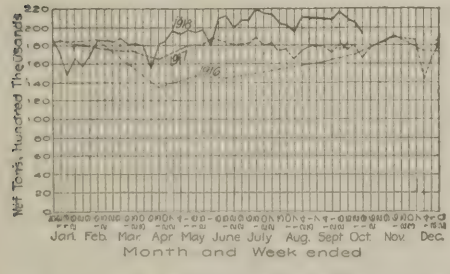
Uniontown, Penn.—Activity in water transportation down the Monongahela River as the Clairton byproduct plant increases its capacity for coal has resulted in several steamers changing hands, and within a short time new boats will be put in the river service. The Carnegie Steel Co. has purchased the steamer "Monitor" from the Diamond Coal and Coke Co. for $70,000 and has added it to the regular towing fleet. Within a short time the "W. H. Clingerman," the new stern wheeler being built in Pittsburgh, will be placed in service. Captain John F. Klein has sold the steamer "E. F. Jackson" and a fleet of 21 barges to the Lyons Coal Co. at Fairmont, W. Va. Coal will be towed from the company's operation there to the Pittsburgh harbor. The consideration was $27,000.

MARKET DEPARTMENT

Weekly Review

Coal Production Affected by Influenza Epidemic—Output Still Ahead of Last Year—Need for Economy—Domestic Sizes of Anthracite Scarce—Small Sizes Plentiful—No Prospect of Bituminous Shortage.

BOTH anthracite and bituminous coal suffered a setback during the week ended Oct. 19, owing to the epidemic of influenza in the mining regions. The 11,523,000 net tons of soft coal produced in the week under review, though 800,000 net tons behind the output of the week ended Oct. 12, exceeded by 1,300,000 net tons the production during the same period of 1917. Reports show that influenza caused a decrease in the shipments of soft coal from all fields except western Pennsylvania. The epidemic has not helped the anthracite situation. Production of hard coal during the week ended Oct. 19 totaled 1,715,000 net tons compared with 1,955,000 net tons the preceding week. The total output of anthracite from April 1 to date is estimated at 57,573,000 net tons, as against 56,736,000 net tons for the same period of 1917.



Though the country as a whole is rather well supplied with bituminous coal, the necessity still exists for the exercise of the strictest economy. The quantity of anthracite distributed so far this year to those sections which are permitted to burn hard coal is greater than in normal years. The demand for domestic sizes is strong.

Prepared sizes of anthracite, such as egg, stove and chestnut, are scarce. Many consumers have been advised to purchase the smaller sizes, and mix it with the larger grades. The small sizes of anthracite are plentiful and in order to move some of their surplus stocks of these coals several shippers have been cutting the prices somewhat.

Summed up concretely, the coal situation can be said to be generally satisfactory. There is no prospect of a serious shortage in bituminous, and the belief is expressed that domestic consumers will receive their share of anthracite before November closes.

WEEKLY COAL PRODUCTION

Production of bituminous coal for the week ended Oct. 19 not only decreased 800,000 tons, or 6.7 per cent., due to the influenza epidemic, but fell to the low weekly record of last May of 11,500,000 net tons. Preliminary estimates place production during the current week at 11,523,000

net tons, and while 800,000 net tons below the week of Oct. 12, exceeded production during the corresponding week of 1917 by 1,300,000 net tons, or 12.3 per cent. The average production per working day is estimated at 1,920,000 net tons, during the week ended Oct. 19, as compared with 2,056,000 net tons during the week preceding, and as against 1,702,000 net tons produced during the week ended Oct. 19, 1917. The average daily production for the coal year to date is estimated at 1,992,000 net tons, which is slightly below requirements, and in order to make up the deficit it is necessary that daily production during the balance of the coal year should be equivalent to 2,039,000 net tons, or 2.4 per cent. in excess of the average daily production to date. Carriers' reports show that the influenza epidemic caused a decrease in shipments from all fields with the exception of western Pennsylvania.

The influenza epidemic also caused considerable loss in the anthracite fields, and production during the week ended Oct. 19, estimated at 1,715,000 net tons, is a decrease of 240,000 net tons, or 12.3 per cent. compared with the week of Oct. 5. The daily average during the current week is estimated at 286,000 net tons, as compared with 326,000 net tons during the week of Oct. 12, and as against 335,000 net tons during the coal year to date. Total production for the period Apr. 1 to date is estimated at 57,373,000 net tons compared with 56,736,000 net tons for the same period of 1917.

Production of beehive coke in the United States during the week ended Oct. 19, is estimated at 575,000 net tons, a decrease of 25,000 net tons or 4 per cent. compared with the week preceding. The average daily production is estimated at 96,000 net tons as against 100,000 net tons during the week ended Oct. 12.

The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke during the week ended Oct. 19 at 360,488 net tons, and the operation of their plants at 75.1 per cent. of full time as compared with 77 per cent. during the week ended Oct. 12. In addition to labor shortage which was, as in previous weeks, the limiting factor, shortage of coke cars caused a loss of 2.5 per cent. of full time, as against 0.9 per cent. during the week preceding.

Byproduct coke plants of the United States were operated during the week ended Oct. 19 at 91 per cent. of their full time as compared with 91.3 per cent. during the week preceding. Of the total loss of 9 per cent. 1.3 per cent. was due to lack of byproduct coal, 0.6 per cent. to shortage of labor, 5.7 per cent. to repairs to plants and 1.4 per cent. to other causes.

Material improvement was reported during the week in the Maryland, Pennsylvania and Tennessee plants. In Maryland the operators attribute the improvement to better labor conditions, in Pennsylvania, to other causes, and in Tennessee, to repaired plants. Operators reporting a noticeable decline in production during the week ended Oct. 19 compared with the week preceding were those in Kentucky, Minnesota, New Jersey and Ohio. In Kentucky and Ohio, the limiting factor was repairs to plants, in Minnesota, other causes, while in New Jersey, the lack of byproduct coal curtailed production.

BUSINESS OPINIONS

Marshall Field & Co.—Current distribution of dry goods is slightly in excess of the corresponding week of 1917. The volume of road sales for both immediate and spring delivery is well ahead of the same period last year. There was a falling-off in the number of merchants in the market. Collections continue good.

American Wool and Cotton Reporter—Release of wool for civilian purposes is the subject of some discussion in the wool trade. It is not likely, however, that any wool will be released before the first of the year, for it is understood that the Government wants to be absolutely sure that there is plenty on hand for its needs before any is sold to the manufacturers for civilian purposes. No great change has taken place in the cotton market during the week under review. Brokers are not looking for any big drop in the market.

Dry Goods Economist—The order issued by the Priorities Division of the War Industries Board, limiting the production of silk goods of all classes to a maximum of 50 per cent. of the average quantity produced in 1915, 1916 and 1917, has caused no serious comment, it being recognized that for months past the output has not exceeded 60 per cent of the average of the last three years in any line of silk goods and that in many lines it has been as low as 40 per cent. The order is effective as of Dec. 1, and is to continue in force for six months.

Bradstreet's—Maintain production and speed it if possible, is the order of the day in the iron and steel line, and such essentials as plates and sheets are in great demand, while mills making barbed wire for export to France are oversold; but on the other hand, calls for pig iron have abated somewhat. Besides buying heavily of oats, the government is expected to soon give out large orders for woolens, and contracts for auto trucks, calling for the expenditure of $132,000,000, practically have been placed. Shortage of labor is as marked as ever, in some sections more acute, in fact, and even the most essential plants complain of the frequency of the turnover, but from some quarters come intimations that munition and powder plants may soon provide relief in this respect.

The Iron Age—The quieting effect of peace talk has been noticed particularly in the markets for pig iron, scrap and ferro-alloys, all of which have until lately shown more freedom of action than finished steel. Some pig iron sellers are protecting themselves by the proviso that unless changed by Government action the present prices shall apply on all iron delivered under the contract. Thus if the war ended suddenly and the controlled price policy were terminated, the prices now prevailing would continue to be the basis of settlement. Consumers have not taken kindly to these riders in the case of allocated iron. The distribution of 137,000 tons of barbed wire to the Allies—65,000 tons to Italy, 50,000 tons to France and 22,000 tons to Great Britain—and the setting aside of 60,000 tons for the United States have tied up most of the wire capacity for some time.

Atlantic Seaboard

BOSTON

Chief factors of situation are influenza epidemic and volume shipments overseas. Hampton Roads dumpings for New England continue light. Baltimore clearances also relatively few. New York piers slow dumping because of sickness. All-rail receipts average about as last week, but less regular, due to local conditions. Wagon coal practically ceased moving to this territory, at least through Fuel Administration channels. Less heard of coal offered for delivery extending over twelve months period. Anthracite shipments by water improve slightly. "Storrow anthracite" coming mostly from "independents" is less eagerly sought, although there are still many holes.

Bituminous—New England is thoroughly well stocked with steam grades, but there is yet a little doubt whether current requirements will be allowed to come forward in sufficient tonnages. The war program so far as industrial plants are concerned shows no sign of easing off, and it is only because of the tremendous effort in July and August to "stuff" New England that the situation here is so quiet in a coal way. The cost of all-rail deliveries from Central Pennsylvania at practically every point in this territory is less than any coal by water, and that of course restricts current buying of water-borne coal to a minimum. All buyers are taking their commitments, provided the fuel authorities leave the way open, and it is only this possibility of interference always hanging over us that today gives occasion for any anxiety as to the coming winter.

A number of lake-built steamers of around 2500 to 3000 tons have now been substituted for the larger colliers that were taken for transatlantic carrying. In a more restricted sense, therefore, contract coal is coming forward from Hampton Roads. Deliveries are less regular, and generally the use of smaller steamers will mean a distinct curtailment in receipts at this end. Dumpings for New England have fallen off materially and from the standpoint of the distributor inland it is well they have. To place any more coal than is now being absorbed, and still follow the directions of the various state administrators, would be at least embarrassing to the wholesaler. Average dispatch at the Norfolk and Newport News piers is now from three to four days, a marked improvement over conditions a month ago.

Baltimore loadings for New England are also very light. Line and offshore requirements have stiffened the past fortnight, and these together with the slack in production and the disinclination of shippers to risk sending coal to Boston for distribution have had their effect. Except for railroad purposes we are likely to get less coal from Baltimore this winter, although it is possible that a new blocking out of territory by the fuel authorities at Washington will make a difference in this.

At New York the loading piers are still seriously handicapped by the lack of men to handle coal as it arrives. At times there has been only a corporal's guard to dump long lines of cars, and meanwhile bottoms have waited and demurrage has accrued. In some cases barges have waited in excess of two weeks and have then been taken away to load at other piers. At Port Reading manifestly too much has been attempted. In the opinion of several who are competent to judge, the Railroad Administration will be forced to resume sending P. & R. barges to Philadelphia, at least in part, unless the use of valuable transportation is to be wasted.

For the seven days ending Oct. 24 the receipts of commercial bituminous at the five New England gateways averaged 383 cars. The movement of railroad fuel has again dropped off to about 150 cars daily, so that the total movement of bituminous is now down to about 535 cars per day, or only slightly less than a week ago. Daily receipts have been much less even, however, due doubtless to suspensions local in the mining districts.

In the Central Pennsylvania district wagon-coal is still being distributed by the Fuel Administration, but calls are sufficient from other sections to take care of current receipts without sending much to New England. In fact, the receipts here of wagon coal through Administration channels have practically ceased. There has been a sentiment here in some quarters none too cordial to the effort made by the District Representative to clear up the box-car situation, but there was enough support at the time it was most needed. The cars came forward, they were placed, and the billing was most carefully supervised. The result is an end to price-monkeying on wagon coal and for his courage and initiative in carrying through a difficult program Mr. Cameron deserves much praise.

This week there is less talk of contracts being offered for delivery over a twelve months period. So far as we are advised there has been practically no business closed on this basis.

The local fuel authorities are again busily revising their embargo lists to conform to the most recent modification from Washington of the rule covering permissible reserves. In Maine non-essentials are now allowed to have 90 days supply, where a few weeks ago, had the rule been strictly adhered to, a number of plants would have been practically put out of business.

Anthracite—Shipments of domestic sizes have increased slightly by water the past week, although the comparison is with the first three weeks of the month when New York loadings had dropped way off. As it is, a large proportion of the cargoes coming forward have broken and pea sizes, with only small doles of either stove or chestnut. The Boston Fuel Committee is expected to issue an order directing dealers to deliver with each order for domestic sizes some stipulated proportion of pea. Rail receipts at the five New England gateways are practically on the same footing as a week ago, an average of 400 cars daily, domestic sizes.

It develops that most of the free "Storrow anthracite" coming forward is from "independent" operators, and therefore carrying the 75c. additional. As rural dealers come to realize this they are inclined to rely more upon their regular sources of supply, and the result is that this emergency supply is somewhat less sought after. This is quite likely to change, however, with the approach of more seasonable weather.

NEW YORK

Influenza epidemic cuts production at the rate of nearly a quarter million tons each week. New England wants more hard coal, but boats find it difficult to get cargoes. Physicians are sent into the coal fields to fight malady. Bituminous market in good shape. Manufacturers are well stocked. Bunker situation serious.

Anthracite—Receipts of anthracite here have been further reduced because of the influenza scourge throughout the coal regions. Production is being curtailed at the rate of nearly a quarter million tons weekly in spite of the efforts of the Fuel Administration. The epidemic has also left its imprint on the local situation, workers at the loading docks having in some cases been reduced to one-fifth of their normal number and the local dealers, already short of help, being further hindered in their deliveries.

Dumpings at the local piers for the seven-day period ending Oct. 25 were 5597 cars as compared with 6050 cars the previous seven days, a decrease of 453 cars. With the exception of the week ending Oct. 11 this was the lightest in several months. Should similar conditions continue for any length of time, they will have a serious effect upon the program of the Fuel Administration and dealers to give every consumer at least part of his winter supply of fuel before cold weather sets in.

Not only is New York feeling the effects of the curtailed production, but towns along Long Island Sound and as far north as Maine which receive their coal in small schooners from this port are hard-hit. The lack of fuel at this time means considerable to these small towns, many of which are so far removed from a railroad that if coal could be shipped by rail it would mean a long haul by wagon to the place of consumption.

The State Fuel Administration is advising consumers to mix the small anthracite sizes with those ordinarily used, telling them that they cannot get a full supply of stove and chestnut for the reason that only 41 per cent. of the anthracite mined comes through the screens in these two sizes.

The local market is being crowded with the smaller sizes from pea down to and including No. 4 buckwheat and culm, while the prepared coals are becoming scarcer and harder to get. There is scarcely any egg, stove or chestnut in the market, orders for these two sizes being placed far ahead so that the dealer anxious to find a loose lot finds it difficult to obtain it.

Pea coal is plentiful, but the demand is not heavy. Buckwheat and the smaller sizes are nearly a drug on the market and various shippers have been cutting prices slightly in order to move their surplus. Retail dealers are not anxious at this time to take any more of the small coals than they have a market for, hence the overstocks in the hands of the shippers and producers who have no place to store it.

Retail dealers are being hard pressed. They cannot obtain all the coal they want and on the other hand if they could they would not have the help to take care of it. Between the lack of labor and the influenza epidemic raging in the city, the dealers are in a quandary, but hope to be able to give all of their customers some coal between now and the first of November.

Current quotations, per gross ton, f.o.b. tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$6.75	$7.50	Buck	$5.10	$5.90
Egg	6.65	7.40	Rice	4.65	5.10
Stove	6.90	7.65	Barley	4.15	4.30
Chestnut	7.00	7.75	Boiler	4.60	
Pea	5.50	6.25			

Bituminous—At this port receipts show a decided decrease, but loadings based upon the tonnage received show a better average than existed a couple of months ago, and this in view of the fact that the working forces at the various docks are greatly depleted because of the epidemic, some of the docks having about one-fifth of their usual working forces on hand.

The dumpings at the local docks for the week ended Oct. 25 were 6430 cars, a decrease of only 13 cars as compared with the previous week, but, with the exception of the week ended Oct. 11, the smallest week in several months.

Locally the situation as regards commercial coal is not serious. There is plenty for all, as most owners of essential plants are well stocked and under the new regulations regarding the storage of coal all

others are now permitted to carry larger stocks than for some time past. Large consumers are not now inclined to add to their stocks, preferring, presumably, to take chances of picking up some coals at lower prices later on.

That the situation in New England is much easier is evidenced by the presence here of many empty bottoms used in that trade. Empty boats are to be seen everywhere. This situation is due as much to the lack of anthracite as to the lack of orders for bituminous for points along the Sound and the New England waterfront.

Large producers and shippers of the better grades have a steady call for their product, and some of them claim to be behind on their contracts.

The bunkering situation is not encouraging to shipping interests. Supplies are short and coal is not being received in sufficient quantities to guarantee continuous loading should there be any transportation interruption. The Pocahontas district has been hard-hit by the epidemic, the railroads as well as the mines being the sufferers.

Current quotations, based on Government prices at the mines, net ton f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite receipts short. Illness cuts production 25 per cent. Companies, however, promise to meet allotments. Water yards being filled. Stove and nut still in heaviest demand. Steam coal quiet. Bituminous coal in fair supply. Decreasing production beginning to be felt. Scarcity of gas coal.

Anthracite—This city has probably received less coal during the past ten days than during any similar period of the present coal year. At the office of the largest operating company it was learned that their production is at least 25 per cent. short owing to the prevalent illness among the miners, and that the current shipments are practically all being consigned to tide points and to the western market. Another one of the big companies reports a labor shortage of 20 per cent., with by far the larger proportion of the production also going to tide. At the offices of this company we learned they were giving their Philadelphia trade, located on the P. & R. tracks, positive assurance that they would receive every ton of their quota based on the 1916-17 allotment, and that it was expected to increase same about 20 per cent.

While the trade as well as the public is growing more impatient, yet we can only report that all signs indicate there is no real cause for alarm. Philadelphia will surely be supplied beyond all fear of suffering, providing reasonable economy and wise distribution especially by the dealers themselves, is shown. We are also firmly convinced that the heavy tonnage will not begin to arrive until cold weather sets in. The dealers dread the prospect of being responsible for its delivery to the consumer during the winter months, with the accompanying bad weather. It will be remembered that the local fuel administrator promised to have the suburban dealers supplied early because of the more difficult deliveries in the outlying sections of the city, but it begins to look as if they too would have to wait. Of course, the principal cause of the retailer's concern regarding these late shipments is the labor situation, which is certain to be more difficult to control as the season advances.

Locally the only dealers who have any stocks to speak of are those with water yards. The shippers who were responsible for their supply have all along tried to dispose of their obligations to them while navigation is open. When prices advance these dealers are wondering if the fuel authorities will allow them to charge the new rates for the coal on hand.

There are no stocks to speak of. The supply of egg that a few dealers had accumulated is rapidly disappearing. The same is true of pea coal, but it had been stored in larger quantities. Stove and chestnut is in as much demand as ever and is in even shorter supply than at any time during the past month.

Attention has recently been directed to the peddler trade, who it is estimated supply about 15% of the city's domestic coal requirements. Although efforts are being made by the fuel administrator to protect the small buyers who are usually supplied with a bucketful at a time at a greatly increased cost to the dealer, the prices fixed under the present ruling will cost small buyers at the rate of $19.10 for chestnut and $16.70 for pea coal. These are the sizes handled almost exclusively by the peddlers. Stores handling coal by the bucket and bag are compelled to sell at 3c. less than the peddlers, the prices being 19c. and 16c. for nut and pea respectively in bags, and 13c. and 11c. in 10-quart buckets. The difference in price is due to coal being handled as a side line by storekeepers, and they are thus not put to the same expense as the peddlers.

The steam coals still continue to be very quiet. While there is no particular heaviness with buckwheat, yet on the other hand users of this size are doing very little urging for increased shipments. Those concerns who have been permitted to stock this coal have ample piles, and while they do not refuse additional shipments, in many cases it is for the reason that they do not want to hurt their case when the pinch comes this winter. Rice is quite plentiful and some of the larger companies continue to place a light tonnage in the storage yards near the region. The same can also be said of barley. Culm is out of the market.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous.—While the market continues to be fairly well taken care of, there is beginning to be some evidence of a falling production. Many operators report the influenza epidemic as reaching its height in the western part of the state now, and it is thought by the end of the week there will be a somewhat serious shortage. One operator advised us that 50 per cent. of his men are out on account of the illness. The miners are also somewhat restive due to their wage demand having been denied by the National Administration.

In this market there is a particular shortage of gas coal, which is principally used by the steel plants in and about the city. Some of the largest plants have only a five-day supply ahead. Much of this coal comes from the Greensburg district, and the statement is made that relief cannot be expected from that quarter for some time on account of the illness now prevalent there.

BALTIMORE

Influenza continues to play havoc with production and distribution of soft coal. Demand growing steadily as consumers run low on their stored stocks. Improvement in grade of shipments. New order disturbs jobbers. Hard coal situation unimproved.

Bituminous—Influenza still holds the upper hand in this section. Not only do mine reports show efficiency cut from 30 to 50 per cent. by the disease, but the Baltimore & Ohio R.R. is seriously crippled and has been shipping less than half of its normal coal tonnage. In distributing the coal coming through there are complications due to inadequate pier handling forces.

The demand is growing steadily, as the stored stocks of both non-essential and essential industries run below their permissible 15- and 30-day allotment. Several industries that had been cut off the delivery list for weeks because they had stored from 60 to 120 days ahead before the Fuel Administration's limitation order are now back in the market for more coal.

A feature of interest just now is the steady improvement in some of the box-car coal coming through. For such coal consumers have been entirely willing to pay the added price on box-car movement and for unloading. The old jobbing trade is somewhat disturbed over a new order from the National Fuel Administration which says that all coal requisitioned on the order of a state administrator shall at his request be invoiced to a licensee named by the purchaser, unless the producer prefers that it be invoiced directly to the purchaser. Such licensee named by the purchaser may, if the coal is invoiced to him, charge a purchasing agent's commission subject to the rules and regulations governing licensees. Purchasing agents here feel that this may result in mines dealing direct with many of the best customers they have had for years, and for whom they have at times recently been forced to appeal to the fuel administrator to get requisitioned coal to cover their contracts.

Anthracite—Little or no improvement is noted in the hard-coal situation. Coal is now coming through at the rate of about 50,000 tons a month, while there still remains about one-fourth of the homes of the city without coal. Some dealers here are still giving two-thirds on orders when they get coal, while others deliver in one- and two-ton lots. Probably 30,000 homes will still be without coal when cold weather arrives. The receipts here since last April have not only fallen below the allotment for the city, but have fallen below the receipts for the same period of last year. This spring, also, the city started off with a deficit of probably 75,000 tons, as against the yard and home holdover supplies of the previous spring. The local fuel administrator is now advising householders to burn soft coal. The trade also faces the fact that just now a large proportion of the coal coming in is of sizes which are unsuited to their household trade.

Lake Markets

PITTSBURGH

Price shading in some Ohio districts, but wider distribution now allowed. Heavy pressure on Pittsburgh district for lake coal, particularly gas and by-product. Serious effects of influenza.

The market for coal in the Hocking, Goshen and some other Ohio fields has been soft, and at times there has been considerable price shading. Some coal allowed a Government limit of $2.90 has sold down to the general standard of $2.35. A part of this congestion arose from the recent recasting of zone limits, whereby more territory was given to Indiana and Illinois, this being followed lately by a curtailment in the amount of coal that could be received for lake movement, on account of vessel and dock conditions. The situation is likely to be relieved, and a broader market furnished for the coal that is in excess of demand, by the recent opening of the Black Rock, N. Y., gateway, giving Ohio coal a wider field.

As to the Pittsburgh district there is no relaxation in the pressure for lake coal, as gas and byproduct coals are given precedence in the matter of lake carriage, and such coal must come chiefly from this district. As noted a fortnight ago, the coal distributor has been permitted to divert 200 carloads additional weekly to retail dealers, and lake shipments are at a correspondingly lower rate; but hopes are entertained of shipping 300,000 tons a week to the lakes from the district unless production is seriously curtailed.

Influenza has been affecting production of coal more than a week ago, some mines being seriously affected while others are almost free. The influenza is much worse in the Connellsville region than in the Pittsburgh district. No opinion is hazarded as to whether the epidemic has passed its crest, as it has a way of affecting large centers of population first and then working out into regions where population is not so dense.

There are no market transactions in Pittsburgh coal as all coal is moving under contract or allocation, but there has been some activity in coal from a few Ohio districts. The market remains quotable for the district at the set limits: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, with 15c. brokerage allowed to be charged in addition by regular brokers.

BUFFALO

Bituminous more plenty. Some shippers say the market is pretty flat. Consumers do not seem to be afraid of a serious shortage right away. Influenza affects mining. Anthracite very short locally.

Bituminous—The trade is easier than it has been in a long time. There is still complaint of coal being ordered to various consuming plants, some of them here, faster than it can be unloaded, so that while the consumers that the shpipers are trying to serve are going without coal the concerns that do get it are paying demurrage. What the shippers hope for now is coal enough before long so that no further commandeering will be practiced. At present the railroads are taking large amounts.

In general the jobbing interests are selling only small amounts of coal, though a few manage to get near enough to the operators to obtain a pretty good tonnage. The jobbers generally agree that the zonal authorities are still undermining them, and

that if the present method of distributing the coal continues long the business of the middleman will mostly be transferred to the zones.

All reports agree that the active manufacturing plants the country over are pretty well supplied with coal, so that they can afford to buy soaringly for awhile and most of them seem to be doing so. Slack is especially plenty and only lump is at all scarce. Prices continue on the basis of the Government figures, $4.65 for Allegheny Valley thin vein, $4.45 for Pittsburgh lump, $4.20 for Pittsburgh mine-run and slack, $5.85 for smithing and smokeless and $5.60 to $6.10 for cannel, all per net ton, f.o.b. Buffalo.

Anthracite—The complaints of no coal are heard about as much as ever. They are met as before by statements from the fuel authorities that they are taking care of every emergency case, and that the winter's supply will be forthcoming before it is needed. As a rule the city anthracite distributors are declaring that they have kept up former delivery amounts, but their neighbors have not. It will all be easy if the shipments to the lakes are turned in on the city a short time after the lakes close early in December. The influenza is cutting down the production and may make a serious difference with the movement if it continues. It has not abated to any extent yet here.

Shipments by lake are about as formerly, being for the week 107,633 net tons, of which 57,400 tons cleared for Duluth and Superior, 15,000 tons for Milwaukee, 17,233 tons for Chicago, 5500 tons for Port Arthur, 3000 tons for Gladstone, 2700 tons for Fort William, 2500 tons for the Sault, 2400 tons for Manitowoc, 1000 tons for Depere and 900 tons for Lake Linden.

Freight rates remain strong at $1 to Sault and Depere, 48 to 75c. to Lake Linden, 60 to 65c. to Chicago, 55c. to Milwaukee, 50c. to Manitowoc, 48c. to Duluth, Port Arthur and Fort William.

CLEVELAND

Bituminous for the lake trade is tapering off somewhat—though October shipments will come close to exceeding the schedule by 1,000,000 tons—while the receipts for domestic and industrial consumption have gained in proportion. Domestic orders are on the decline, indicating the well-coaled condition of the district. Improved car supply is aiding in offsetting lost production attributable to influenza.

Bituminous—Receipts for the industrial and domestic trade, as well as for dumping for the Northwest, are holding up remarkably well in the face of the epidemic of influenza that is sweeping the No. 8 district. While some mines have been forced to suspend entirely, others have scarcely been affected. On the whole, the inroads have been more mild than expected, though many operators fear the crest has not yet been reached. More serious inroads seem to have been made on the train crews of the roads supplying southern Ohio mines. Car supply, despite this handicap, is averaging 85 per cent. or better. The real truth of the labor situation is almost impossible to determine because of the sick lists.

The movement of bituminous into Cleveland and northern Ohio for industrial and domestic consumption is slightly heavier, at the expense of the lake trade. For the first time, a falling off in new business is noted by domestic dealers. Their increased receipts, however, are more than taken up by deferred business. Industrial stockpiles, which only in rare instances are below the 30-day mark and run as high as 120 days in instances, continue to be added to, and advantage is being taken of the extension of stocking limits. This is most comforting to operators, who point out that the one factor that will cut off spot shipments this winter—extreme cold paralyzing the railroads—will at the same time increase consumption out of all normal proportion. Some fair-sized lake shippers of coal, who assert they have been most diligent in heeding the Federal Fuel Administration's admonitions in regard to contracting, assert that all but 25 per cent. of their contract business will expire with the closing of navigation on the Great Lakes the middle of December. While they expect industrial and domestic demands will take up whatever slack results, they predict that many wagon mines will be compelled to close. A slight surplus of coal is looked for by some interests unless much more than the expected tonnage released by the lake trade is diverted toward the east. The report of the Pittsburgh Vein Operators' Association of Ohio on car supply to its members for the week ended Oct. 12 places the shortage of cars in that week at an average of 28.41 per cent., and the lost production chalked up to this factor as 119,100 tons. The average car shortage in the preceding week was 15.49 per cent. The diversion of all B. & O. cars to the Fairmont region for the last half of the week is blamed for the extremely poor showing. Shipments in the week ended Oct. 12 totalled 5,419 cars as against 6,103 in the week preceding.

Anthracite—Receipts continue to drag along at from 150 to 200 cars a week, about 25 per cent. of what ordinarily could be disposed of at this time. Upper lake dock interests complain that to Oct. 15 they have received only 1,325,000 tons of anthracite, compared with 1,950,000 tons to the same date last year.

Lake Trade—Unless shipments of bituminous in the last week of the month fall down unexpectedly, the Northwest will have been given fully 4,500,000 tons in October, or 1,000,000 more than the Federal Fuel Administration called for. To Oct. 15 the total bituminous loaded at lower lake ports for the Northwest—exclusive of vessel fuel—is estimated at 23,050,000 tons. From Oct. 1 to 21 the loading is placed at 3,450,000 tons. Receipts at the docks in the last 10 days of the month slumped somewhat owing to the influenza epidemic. Instead of fearing that the Northwest will not get its 28,000,000 tons of bituminous this season, the Great Lakes vesselmen in charge of the downward movement of grain in November and the first half of December are hoping coal operators will purposely slow up shipments in order to leave some coal for ballast in December. Barring the slight recession the past few days, the October movement is proving the fastest of the season, and some operators predict that the high mark set in August, when 4,996,929 tons of both cargo and bunker coal were handled over Lake Erie car dumpers, will be broken.

DETROIT

Reserve piles strengthen position of numerous industrial consumers. Fine weather in October brings relief to many domestic consumers. Lake shipments heavy.

Bituminous—Though there is less coal available in the Detroit market than a few weeks ago, the demand from consumers of steam coal is apparently not urgent. Jobbers explain this as being an indication of successful accumulation of large storage piles by many of the great industrial and manufacturing plants of the city. Profiting from their experience of last year, many of the consumers of steam coal, according to the jobbers, have been gradually building up reserves through a large part of the summer. Some of these consumers have on hand so abundant a supply that they are said to be meeting their present requirements from storage stocks rather than by direct shipments. By following this course a number of manufacturing plants are able to avoid using the coal now coming to Detroit from Illinois and Indiana, which, in the opinion of some of the buyers, is undesirable stock likely to damage furnaces. The supply of steam coal is being augmented somewhat by shipments of slack from mines in Ohio, but not all of the industrial plants are able to handle the fine coal to advantage. Only the continuance of unusually mild weather throughout the month so far has saved hundreds of household consumers from experiencing hardship and suffering. The favorable conditions have made it possible for retail dealers to speed distribution to an unusual degree, despite the handicaps of shortage of labor and, at times, deficient coal supply. The latter difficulty has been relieved by the action of the Federal Fuel Administration in placing an embargo on shipments of domestic lump and prepared sizes from Ohio, West Virginia and Kentucky, except when sent for domestic use or for gas and byproduct plants or railroads. Mine run later was made available for use of the domestic consumers.

Anthracite—Improvement in volume of anthracite receipts, though not very great, has tended to aid in relieving the situation. Base-burner users are still receiving most of the anthracite distributed.

Lake Trade—Coal is moving freely over the lake routes and from present indications shipments in October will exceed 5,000,000 tons. For the week ending Oct. 19 vessels loaded more than 1,800,000 tons of cargo coal.

COLUMBUS

With a serious reduction in output in Ohio fields as a result of the influenza epidemic, the Ohio coal trade is in a rather uncertain condition. There is still a good demand for domestic and lake tonnage. Screenings and mine-run are rather plentiful.

The outstanding feature of the coal trade in Ohio is the reduction in output due to the prevalence of Spanish influenza which has become widespread in mining districts. But the output has not been curtailed as much as might be expected under the circumstances, although it is a serious reduction. There is a marked car shortage on certain railroads, more especially the Toledo & Ohio Central and the Kanawha & Michigan. The shortage appears to be due largely to a lack of train crews to handle the trains promptly. The output in the eastern Ohio field is reduced to about 60 per cent. of normal. In the Pomeroy Bend district it is about 50 per cent., and in the Hocking Valley and Jackson fields it is about 65 per cent.

The domestic trade rules firm in every particular. Retailers have accumulated rather large stocks in order to be in a position to take care of the rush when colder weather arrives. There is a good supply of mine-run in the yards of retailers, but lump is not so plentiful. As a result dealers are in the market for prepared sizes. Retail prices are firm at the levels which have prevailed for several weeks. Pocahontas is not out of the market. There is a fair supply of West Virginia splints, but on the whole the bulk of domestic tonnage comes from Ohio mines. Reports show that a much larger tonnage than ever before has been stored up to the present by householders.

Lake trade is rather active, despite the general reduction in production. The docks of the lower lake ports are busy loading vessels which are being moved promptly. The upper docks are in good shape as the interior movement is prompt. Prospects are for a complete supply for the Northwest unless something unforeseen occurs.

Steam trade is rather slow in many respects, largely due to the oversupply of screenings and mine-run on the local market. Some modifications of the embargo against shipping those grades into Michigan have been received, but these are not yet sufficient to relieve the situation. Storage in the hands of large steam users is up to the limit, and in many cases in excess of the amounts permitted by the Federal Fuel Administration.

CINCINNATI

Production and shipments have been reduced by influenza among miners and railroad men, but demand is not heavy, as weather continues moderate.

In spite of the high degree of activity among industrial plants in this section, calling for a correspondingly large consumption of coal, conditions have brought about the old-fashioned state of a weather market, a thing which was hardly anticipated for this fall or winter. The answer seems to be that storage by domestic consumers, and, to a large extent, by others as well, coupled with such shipments as are coming forward, is taking care of all needs very nicely.

So far during the current month the weather has been mild and pleasant, with very little rain and only a few frosty nights. Inasmuch as the prevalent epidemic of influenza has hit the mining regions hard, this is especially fortunate, as it seems that so many men have been out of the mines on account of illness that production could not possibly have kept pace with a heavy demand. In some sections as high as 50 per cent. of the men have been ill, reducing production to a corresponding extent. However, indications are that the epidemic is on the wane in this section, and it is hoped that another week will see it virtually at an end.

LOUISVILLE

A decrease of 50 per cent. in coal production of the state is claimed as a result of the influenza epidemic. Demand for Western Kentucky domestic draggy. Steam coal generally draggy, as industrial consumers are well stocked, and industrial consumption is lighter due to curtailment on account of illness of employees.

The influenza epidemic is having a serious effect on the coal man at the present time. Many large industrial plants are operating on one wheel due to the shortage of hands brought about by illness, this reducing industrial demands considerably. Domestic demand is dull on account of mild weather, with the result that a slight surplus stock is being accumulated in the local yards. Much trouble is being experienced in securing hands for unloading coal from cars.

At the present time the western Kentucky mines are so short of hands that many of them are down, and the car supply for the first time in months is showing a surplus, although it would be a shortage with normal shipments.

In eastern Kentucky the car supply is fairly adequate for the small shipments moving. It is estimated that the mining sections are not operating more than 50 per cent. full as a whole, as many of the mines are closed.

BIRMINGHAM

Steam market soft despite the restricted output. Domestic demand continues strong while the supply is short. Sickness proves disastrous to production.

Steam coal in the local market is reported easier than at any time before in months, and some distributing agencies report some effort is being required to dispose of the full tonnage at their command. Some industries are said to have accumulated several months' supply ahead and have had shipments suspended temporarily, though railroad fuel is moving in about the normal volume.

There is no semblance of softness in the domestic trade and dealers are unable to get anything like the desired tonnage to fill orders in hand. There is very little coal on local yards, and not an infrequent sight to see them completely bare.

Production took a big slump for the week ending Oct. 12, the output being only 382,846 net tons, or 26,000 tons less than the previous week. This loss was due in a measure to the large number of mine workers suffering from influenza, the epidemic being very much worse during the week just past. Numbers of operations in Walker County worked not more than half time last week while others were closed down entirely. The situation is still serious, both as regards coal production and physical distress. Mines in Jefferson County have also been affected to some extent, particularly in the western part of the county.

Transportation service is now good and ample cars are being supplied. The tug boats and barges purchased by the Government from private interests operating them on the Warrior River in handling coal to New Orleans, Mobile, and other points are now being repaired and will be placed in service soon. It is announced that the Government has appropriated $6,170,000 for the purchase of six towing steamers and 40 steel barges for use in the Mississippi and Warrior Rivers, the barges each having a capacity of 2000 tons.

Coke

CONNELLSVILLE

Production reduced by influenza. Extensive inoculation. Efforts to speed production continue under handicaps. Market conditions unchanged. Blast furnaces fairly well supplied.

Production of coal and coke in the Connellsville region has suffered seriously from the influenza epidemic. Output in the week ended Oct. 19 showed a noticeable curtailment, while there has been a further loss since then. The medical staff of the H. C. Frick Coke Co. took measures early against the disease and have inoculated all employees with the "anti-flu serum," while they are now inoculating members of employes' families when requested. Many of the independent operators are inoculating their men. While the number of cases in the region is large the mortality is reported much lower proportionally than in other districts. Precautions are being taken against men returning to work too soon.

All the machinery of W. L. Byers, production manager for the district, to stimulate production of raw coal and of coke is in operative condition, but actual work in the campaign has been materially interfered with by the epidemic, particularly by the impossibility of holding meetings. Good results are expected in the long run, however. No material shortage of coke is reported by blast furnaces, which seem in nearly all cases to be well supplied, though there is little opportunity to accumulate stocks. There remains much complaint as to the quality of beehive coke furnished, although there has been some improvement since the Fuel Administration started its vigorous campaign nearly two months ago to bring about an improvement in quality. Some furnace managers estimate that one-third the coke operations have shown a market improvement in quality of coke turned out.

There are practically no market transactions in furnace coke, the current output moving against contracts or allocations. In foundry coke there is a little activity and foundries engaged in important work can generally secure supplies without much difficulty. A good trade continues in screenings from old dumps, for household use, and present operations have enough material as a rule to keep them going for two months or longer. The market remains quotable at the set limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over ⅝-in., $7.30; clean screenings from old dumps, over ½-in., $5.50 per net ton at ovens.

The "Courier" reports production of coke in the Connellsville and Lower Connellsville region in the week ended Oct. 19 at 314,045 tons, a decrease of 8875 tons, and shipments of coal out of the region at 246,078 tons, a decrease of 20,475 tons.

Buffalo—The supply is fairly good to the smelting furnaces and is likely to continue, as this district is pretty well provided with byproduct plants. Some jobbers in fuel coke complain of careless preparation, consumers finding it with a high percentage of dirt and other foreign matter. An effort will be made to correct the abuse. Prices run from $2.75, a cut, to $7.68, a regulation figure, at the ovens. Only government prices are allowed on smelting coke. Lake receipts of iron ore are still good, being 367,591 gross tons for the week.

Middle Western

GENERAL REVIEW

Mining districts suffer from influenza epidemic. Market continues weak in both steam and domestic sizes. A serious situation predicted for first of year if steam users do not come into market early.

Influenza has a strong foothold in the mining districts of Illinois, and the situation today is more than serious. We are advised that the tonnage for the week will suffer heavily, some authorities going so far as to state that the production figures will be decreased from 25 to 50 per cent. It will not be a surprise to anyone in close touch with operating conditions in Illinois if the epidemic becomes as serious as it is in the anthracite fields of Pennsylvania and the southeastern district of Kentucky.

Market conditions in the Middle West remain, generally speaking, unchanged. In spite of the fact that coal-carrying equipment continues to move to the mines in the east, and in spite of the fact that the man shortage caused by influenza is beginning to be felt, the market continues weak, both on steam and domestic sizes.

The weakness of the steam market is explained easily, as the majority of the manufacturers have enough coal on hand to last until the latter part of December or the early part of January. The domestic market appears to be purely a weather proposition, and as the weather in this territory has been unusually mild, there has been little purchasing on the part of the retailer.

A number of operators are looking forward and predicting what will probably happen about Jan. 1. As we stated before, the average steam coal user has enough fuel on hand to last until this time, and consequently will not be interested in purchasing additional coal until at least the latter part of this year. As a natural result, the operators will be swamped with orders—far more than they can begin to take care of—and the manufacturers will be out of coal. It will naturally follow that there will be a panic similar, if not more serious, to that experienced last winter. The only way to avoid this threatened state of affairs is to advise the steam user to come into the market early, and gradually; otherwise, nothing can hinder a very serious situation.

CHICAGO

Most of the large industries are well supplied and are not interested in coal. No improvement in the anthracite situation.

Steam coal continues to be offered freely, a substantial tonnage of it at a discount, and little interest is taken in it by the average purchasing agent. Most of the industries have a big supply of coal on hand, and no coal to speak of is being purchased, in spite of the fact that operators are predicting freely what will happen to the tonnage production from the influenza epidemic and from the probable car shortage.

Little interest is shown in anything but the high-grade and well prepared coal from the southern part of the state. As soon as a cold snap comes, operators are anticipating a strong market on all domestic coals, but until then the retail trade will continue weak and erratic.

The anthracite situation does not appear to improve much from day to day. The epidemic in the hard coal field of Pennsylvania will further hinder any favorable developments, and the retailers in Chicago are expressing, pretty generally, an intense dissatisfaction in the manner in which the State Fuel Administration is handling the anthracite problems.

ST. LOUIS

Market continues with a surplus of all coals. Mild weather and no domestic demand. Steam business easy and light, and no storage purchases. Country Demand slow. Cars plentiful and transportation good. Tonnage decreasing.

The local situation is one that continues serious for both operator and retailer. With unbilled coal at the mines in the Standard and Mt. Olive field, the operator cannot look ahead to any extent without figuring idle time on account of no orders. With the domestic demand in St. Louis filled, the retailer finds his equipment idle and his stock eating up the profits.

In the face of these conditions, the Fuel Administration at Washington has not consented to eliminate the zone lines as far as shipments to western Missouri, Nebraska, Iowa and the Northwest are concerned. In these places, which in the past have been the logical territory for Illinois coal, there is a scarcity of fuel.

There are no prospects of any business developing in St. Louis until real, cold weather comes, and that business will be light, both as regards steam and domestic.

The country demand within the zone of Illinois fuels in Missouri and the southeast is pretty well taken care of. Car supply is plentiful and transportation shows considerable improvement.

In the Standard and Mt. Olive field there has been a decreased tonnage at many mines on account of the influenza epidemic. This is not so serious as in the Carterville field, where one-fourth of the men at some mines are idle on account of sickness, and in some places in the state some mines are idle altogether on account of sickness of the engineers, firemen, and other essential men, whose places cannot be readily filled.

The railroad tonnage from all the fields in Illinois continues good. That is the only thing that is keeping business going in the Standard and Mt. Olive fields.

There is still a good tonnage of domestic booked in the Carterville field moving north, but the demand for that coal in the southwest is easy and light, excepting on the Iron Mountain lines proper.

There is no outside coal coming in to speak of, excepting a few cars of Arkansas anthracite, and there is no change in the local price from that of the past few weeks, excepting that Standard 2-in. lump is down to $2.25 and $2.30, and screenings around $1.50. All other coals seem to be holding their own, at the Government maximum, in the face of the surplus.

The prevailing market prices per net ton f.o.b. mines, are:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump..	$2.55@2.75	$2.55@2.75	$2.40@2.70
3x6-in. egg..	2.55@2.75	2.55@2.75	2.40@2.70
2x3-in. nut.	2.55@2.75	2.55@2.75	2.40@2.70
Washed:			
No. 1.....	3.05@3.20	3.05@3.20	.....
No. 2.....	3.05@3.20	3.05@3.20	.....
No. 3.....	3.05@3.20	3.05@3.20	.....
Mine Run..	2.35@2.50	2.35@2.50	2.20@2.30
Screenings..	2.17@2.32	2.17@1.32	1.50@1.60

Special prepration on Carterville is 10 cents extra.
Williamson & Franklin Co. rate is $1.10.
Other fields 95 cents.

SEATTLE

Fuel Administration to conduct campaign of conservation throughout the Northwest. Railroad consumption to be given first attention.

A campaign for the conservation of coal is to be inaugurated throughout the Northwest at once by the United States Fuel Administration, the first effort being confined to the various railroads operating in this section, following which the education will extend to power plants and other industries. E. P. Roesch has been appointed supervisor for the entire district and will have his offices in the Union Pacific depot with W. C. Wilkes, assistant to the regional director, railway administration. The department is not connected with the railroad administration, however. The first meeting called by Mr. Roesch was attended by the railroad superintendents, trainmasters, roadmasters, master mechanics, superintendents of bridges and buildings, road foremen and the chairmen of the brotherhoods of trainmen, and ways and means discussed in unloading and firing locomotives with reference to fuel conservation.

The retail coal trade in Seattle reports a brisker movement in winter storage coal, due likely to the persistent reports here that prices of fuel are to be materially advanced before November and to the curtailment of coal supplies to certain industries. While the curtailment does not apply to home consumers, it has caused a flurry among those who were over-anxious.

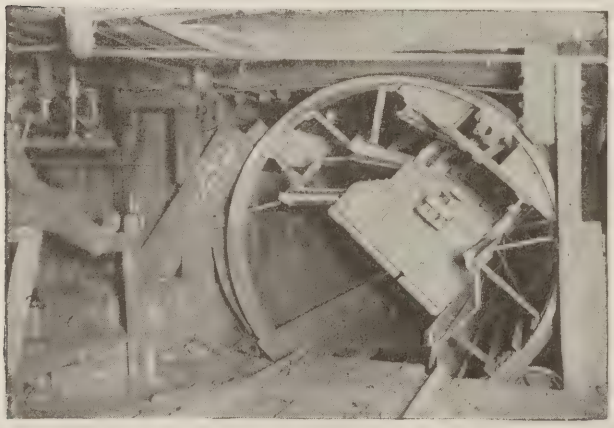
1st —Output Increased
2nd—Labor Saved
3rd—Coal Breakage Minimized
4th —Cars Promptly Released
5th —Mine Car Costs Reduced
6th —Car Repair Bills Lowered

7th —Dust Explosion Risk Lessened

BY using solid cars and the Pneumatic Rotary Dump, most of the coal dust on roadways may be prevented. That is of value in every mine, and particularly in those mines where the dust is of an explosive character.

Of course, cars with open ends or doors can be kept in use with the

Pneumatic ROTARY DUMP



until they are worn out in service. Afterward, when more substantial, less costly solid cars replace them, the fine dust and coal will stay in the solid cars, rather than be distributed along the track.

This is only one of the many advantages of the Rotary Dump. Why not write for Bulletin 180-A and see what are the others?

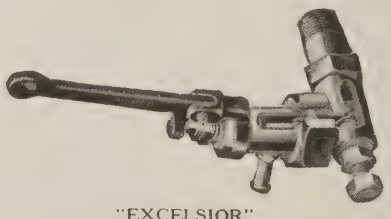
LUNKENHEIMER Water Gauges and Gauge Cocks

"MONITOR" Automatic Water Gauge

are boiler accessories of exceptional merit, possessing qualities which make them the most substantial, practical and durable devices of their kind.

All parts are interchangeable, permitting the repair or replacement of a worn or broken part when occasion requires. Users should follow this principle in preference to discarding the entire device. To repair means to conserve. To conserve means to economize. CONSERVATION and ECONOMY are necessary to our success in the war.

Our "War Period" Appeal



Engineering Appliances Are Prime War Essentials

Stocks of distributors and facilities of manufacturers must be adjusted to care for essential needs.

Lunkenheimer patrons are earnestly requested to assist in the common cause by confining their War Period specifications to requirements for essential plants, craft, vehicles or equipment.

COAL AGE

Volume 14 New York, November 7, 1918 *Number* 19

Let Safety Help the War

DURING the past few months, Uncle Sam has made two demands and one request of the coal industry. All three have been complied with so promptly and willingly that the entire country is proud of the men in and about the coal mines.

The Government has demanded that the men load clean coal at the working face, and that the operator ship only coal that will pass a rigid inspection as being practically free from slate and bone. The nation also demanded that the mines and the individual miners work full time as far as humanly possible. These were followed by the request that the coal companies and their employees invest a large part of their earnings in Liberty Bonds.

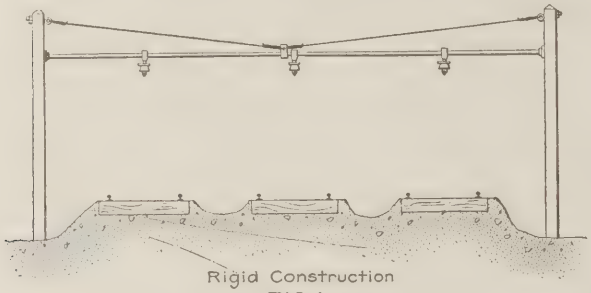
How well the two demands have been met can be determined from a study of the reports of the Fuel Administration and by a comparison of tonnages for 1917 and 1918. The spirit with which the request was responded to is readily revealed by a visit to any mining town, where the honor flag of the Third Liberty Loan and the newer flag of the Fourth Liberty Loan float proudly below the Stars and Stripes.

We now have another duty to our Government —one that is peculiar to this season of the year, and which is especially important at this time. The country needs every ounce of coal that can be produced if our boys on the other side who have the "Hun on the run" are to keep him going. We cannot produce this coal unless we look at once into the condition of our mines and take the necessary steps to insure that they do not, with the coming of cold weather, become so dry that they are in an explosive condition. An explosion that closes down a mine may result in the loss of an important battle, or in the slowing down of a big drive toward Berlin.

Our mines must not get into such a condition this winter that an explosion may occur. It is the duty of every one of us to see to this. Each of us has his part to do in this work, the miners no less than the superintendent.

Mr. Superintendent and Mr. Foreman, your part is to see that there are no accumulations of explosive coal dust anywhere in your workings. Remove all such accumulations at once, and watch carefully for any sources of explosive coal dust. Remember that a dry and dusty mine is a dangerous one. Don't let yours be of this character.

Miners, your part is to see that nothing is done in your working place that may bring about an explosion. Make sure that every shot has a good chance; don't drill a hole "on the dead." The due observance of these precautions will make blownout shots less likely, and you well know that every windy or blownout shot may mean an explosion that may shut the mine down indefinitely —perhaps with you and your buddies inside. If the mine in which you work is gaseous, remember that a smoke after dinner may also cause a serious explosion. Take your last smoke on the surface before going into the mine, and don't run the chance of hindering Uncle Sam by "lighting up" underground.



Let's all keep our mines safe this winter and help put the German back where he belongs.

IDEAS AND SUGGESTIONS

Flexible Trolley Construction for Mines

The more flexible or yielding overhead trolley construction is made, the longer will be the life of the trolley wire and wheels that operate on it. There are some conditions under which it is not feasible to install the trolley from flexible supports. Inside coal mines it is most convenient and economical to attach it to insulated hangers fastened rigidly to the roof or overhead timbers. Also lack of headroom in the mine often prevents the use of flexible construction.

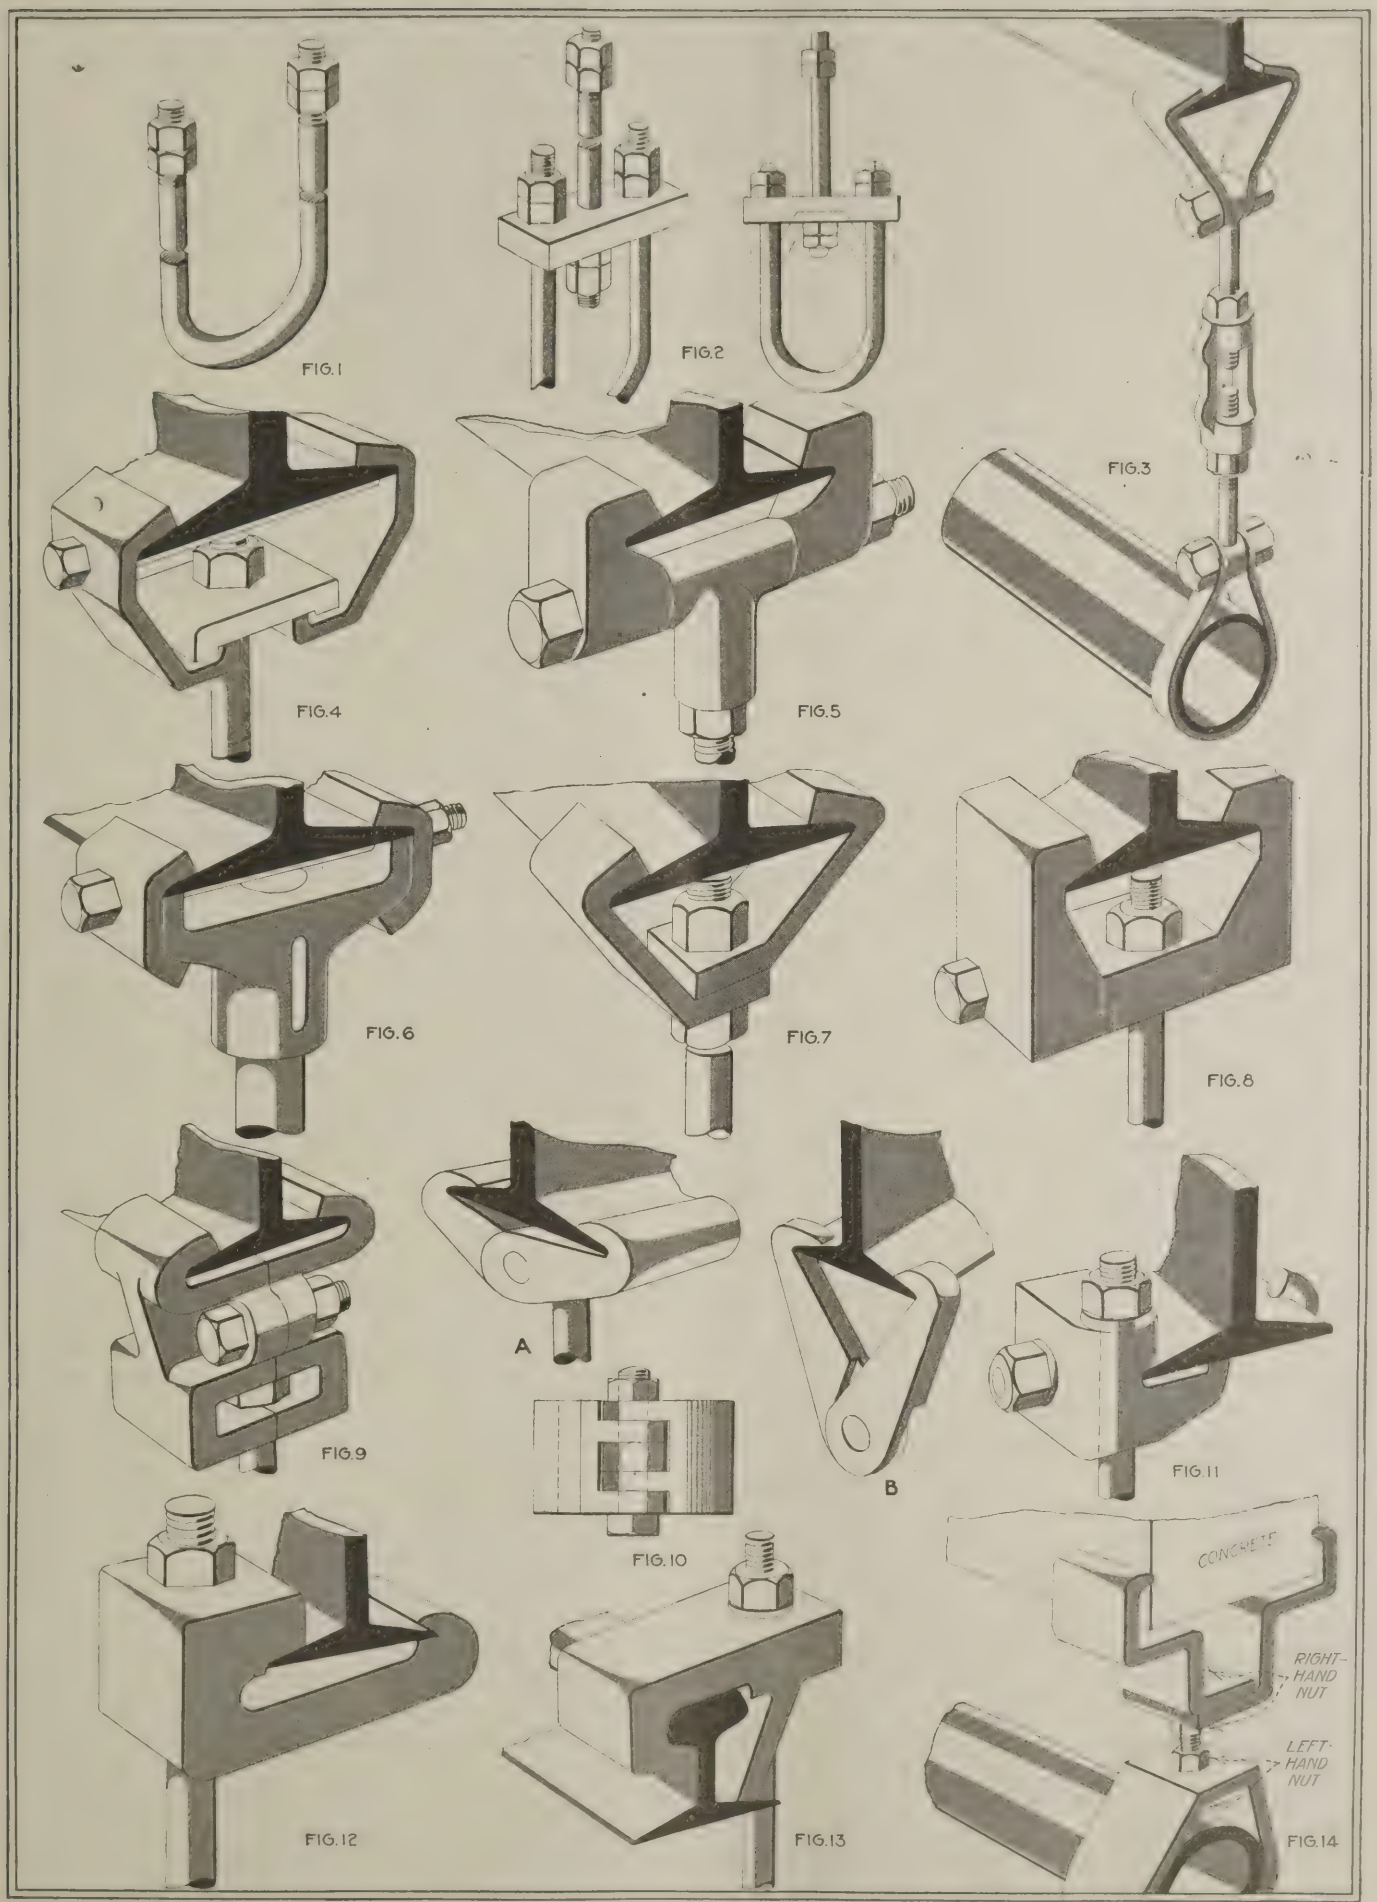
Outside the mine there are no such limitations as underground, and it will be found usually that considerable saving can be effected by suspending the trolley from a flexible cross-span wire. The common practice of continuing outside the same rigid construction that is used inside the mine shortens the life of wire and wheels and requires a large amount of material that could be saved. Great lengths of pipe have been used, some spanning four or five tracks, and quite low, in an endeavor to make the overhead rigid.

FIGS. 1 AND 2. TROLLEY DESIGN FOR MINE WORK

Fig. 1 shows an installation of the rigid type. Hangers are secured to cross pipes spaced about 30 ft. apart. There is a great weight of material to be supported. A better construction for such a condition is shown in Fig. 2. Light $\frac{3}{8}$-in. soft steel cross-span wires take the place of the heavy pipes, hangers are snapped into the strand without cutting and the whole line is flexible, thus insuring maximum life of wheel and wire.

At 1800 lb. trolley tension, which is good practice, a 4-0 hard-drawn trolley wire supported every 30 ft. sags only about $\frac{1}{2}$ in.—*Ohio Brass Bulletin.*

Various Types of Pipe Hangers



The common U-bolt, as shown in Fig. 1, on the facing page, forms about the simplest and cheapest pipe hanger when there exists a suitable structure overhead for attaching it. The rod should be threaded for a considerable distance on each end for adjustment, and for pipes subject to vibration, such as steam, exhaust, hydraulic-pressure lines, etc., there should be jam nuts or other form of nut locks. Where the distance to the joint of support is excessive, or the overhead structure favors attachment at a single joint, the pipe hanger in Fig. 2 is suitable. If a flat bar is used for the cross-beam, it should be bent as shown in dotted lines.

Fig. 3 illustrates a complete hanger with clamp suitable for attachment to the lower flange of an I-beam. The strap in which the pipe rests is made from a broad flat bar of wrought iron or steel, varying in thickness from $\frac{1}{8}$ in., or even less for very small pipes, to $\frac{3}{8}$ or $\frac{7}{8}$ in. for large pipes. A turnbuckle with locknuts provides a means for adjusting the length. The rod ends in the turnbuckle are upset to give the same strength at the rest of the thread as in the full section of the rod, and the whole forms a strong, sightly hanger suitable for nearly any location where minimum cost is not considered a matter of first importance.

A large percentage of the pipes in use at the present time are suspended from overhead beams, and Figs. 4 to 12 show a variety of clamps intended for this purpose. These are mostly designed to be made of steel castings or forgings. On lines subject to shocks, it is useless to attempt the determination of hanger dimensions by calculations of the dead weight to be carried. Only good judgment qualified by experience is of any use in this case, and about the only rule to be followed is the one that says, "When in doubt, make it stronger."

Fig. 10 is commonly made as shown at *A*. There is less stress upon both the pin and the clamps if made as shown at *B*. Fig. 13 represents a hanger on T-rails used for supporting heavy pipes in a tunnel with smaller pipes hung beneath them. In Fig. 14 a pipe is supported with an adjustable hanger by grooves formed in a concrete beam. The strength of the groove was found by experiment to be far in excess of that of the clamps, which were designed of ample proportions for the service required.

Large vertical pipes are usually supported from the bottom by means of a properly constructed special fitting provided with a base for resting upon a suitable foundation, preferably of masonry. Smaller ones may be suspended from above by rods connecting to a split collar placed beneath a convenient pair of flanges. Sometimes a vertical line is supported about midway of its length by a fitting made of a bracket form and bolted to the wall.

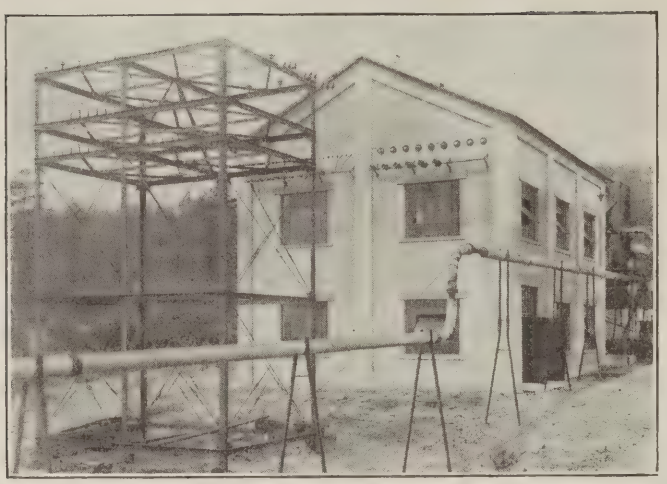

FIG. 1. SUBSTATION AT TAMAQUA COLLIERY

Modern Substations of Large Anthracite Distribution System

THE electrical equipment of some of the larger anthracite mining companies of Pennsylvania is the finishing touch to a development which has taken years to bring to its modern high state of efficiency. A number of the large companies in the anthracite field are committed, to a greater or less degree, to an electrical policy. Prominent among these is the Lehigh Coal and Navigation Co., whose main collieries are operating in the Panther Creek Valley, which is an eastern extension of the southern region of the anthracite field. Here, in a section 1½ by 10 miles in area, is installed an 11,000-volt distribution system which includes 23 substations.

Among the larger substations is the one at the Tamaqua colliery, shown in Fig. 1, which is typical of all the substations of this class. These buildings are among the finest in the anthracite coal region—the most modern in construction as regard building and equipment. They are built of hollow tile, cemented over, inside and out; concrete is used for foundations and floors, and fireproof construction is further secured by the use of red asbestos protected metal roofing, made by the Aspromet Co., of Pittsburgh, Penn. The smaller substations are made with a wood frame covered with Hyrib outside and cement inside to keep down the fire risk.

The electrical development of the Lehigh Coal and Navigation Co. as regards distribution and substations is of the indoor type. As current is distributed at 11,000 volts, nothing would seem to be saved or gained by putting in expensive outdoor equipment, such as switches, transformers and so on. What would be saved in buildings would be expended on equipment of the outdoor class. On the other hand, in high voltages, G. M. Kennedy, electrical engineer of the company, advises that money be invested in outdoor equipment rather than in buildings.

Electrical power is generated at the Hauto power station—a 25,000-kw. installation located in the adjoining valley to the north of the Panther Creek. There are 11,000-volt tie lines connecting the main Hauto plant with the substations. These lines are used in case of failure of any of the main transmission lines from Hauto and were not installed as tie lines, but were the original transmission lines from the old power house, which has been abandoned. Rather than discontinue these old lines it was found that with little expense they could be converted into tie lines which would connect the various substations with the power supply. The substations were built by the company, and all equipment was installed by the company's engineers. The iron work connected with the substations and lines was made at the Lansford shops of the company. The main transmission lines were owned by the Lehigh Navigation Electric Co. —the original power plant holding company—but now they have been taken over by the Lehigh Coal and Navigation Company.

The 11,000-volt transmission system to the various plants is shown in Fig. 2. This illustration was not taken from a scale drawing and merely shows the approximate relation of the more important substations to each other and to the Hauto power house. There are 23 substations in the Panther Creek Valley and four in the valley to the north. Some of the main substations and the horsepower of each are as follows: Lansford, 4200; Greenwood, 3240; Nesquehoning, 3160; Tamaqua, 2312; Hauto washery, 1100 and the North End pumping station, 700.

The type of larger substation is illustrated in Fig. 1; in which is shown a distributing tower and the wire connections to the building. The prominent steam pipe line shown in the illustration will have a limited life, for it supplies steam to an engine driving a fan which adjoins and is almost hidden by the substation; the fan will shortly be electrically driven and the steam line will be removed.

There are two 11,000-volt, three-phase and 25-cycle incoming lines from the Hauto plant to the substation; both lines are kept active supplying power to the bus, but in case of either line going out of service for any cause the entire load is carried on the other line. Each

of these lines is tested often enough to insure that both are capable of carrying current and are equipped with electrolytic, or aluminum cell, lightning arresters of Westinghouse manufacture. These arresters have disconnecting switches for the purpose of disconnecting the power to the arresters to enable making any repair or inspection of the arresters.

Continuing with the description of the course of the current through a substation, the process and equipment at substation No. 14, or Tamaqua, is typical and will be noted as an illustration. Here the lines pass through disconnecting apparatus and choke coils to oil circuit breakers and thence through disconnecting apparatus to 11,000-volt busbars. These busbars are composed of

Equipment is installed for a future bank of three (500 kv.-a. each) transformers, 11,000 to 2300 volts. Also a bank of three transformers, the required capacity of which is not definitely decided upon as yet. The equipment is also installed for an outgoing line from this bus to furnish power to outlying points at Tamaqua or other collieries in the vicinity. Connected at the end of this bus through disconnecting switches and proper fuses are two potential transformers (11,000 to 110 volts) for supplying potential to all voltmeters, wattmeters and power factor indicators in the substation.

The 2300-volt transformers mentioned above are used to furnish power to the 1200-hp. water hoist and also to the 375-hp. tender hoist. This is done by running

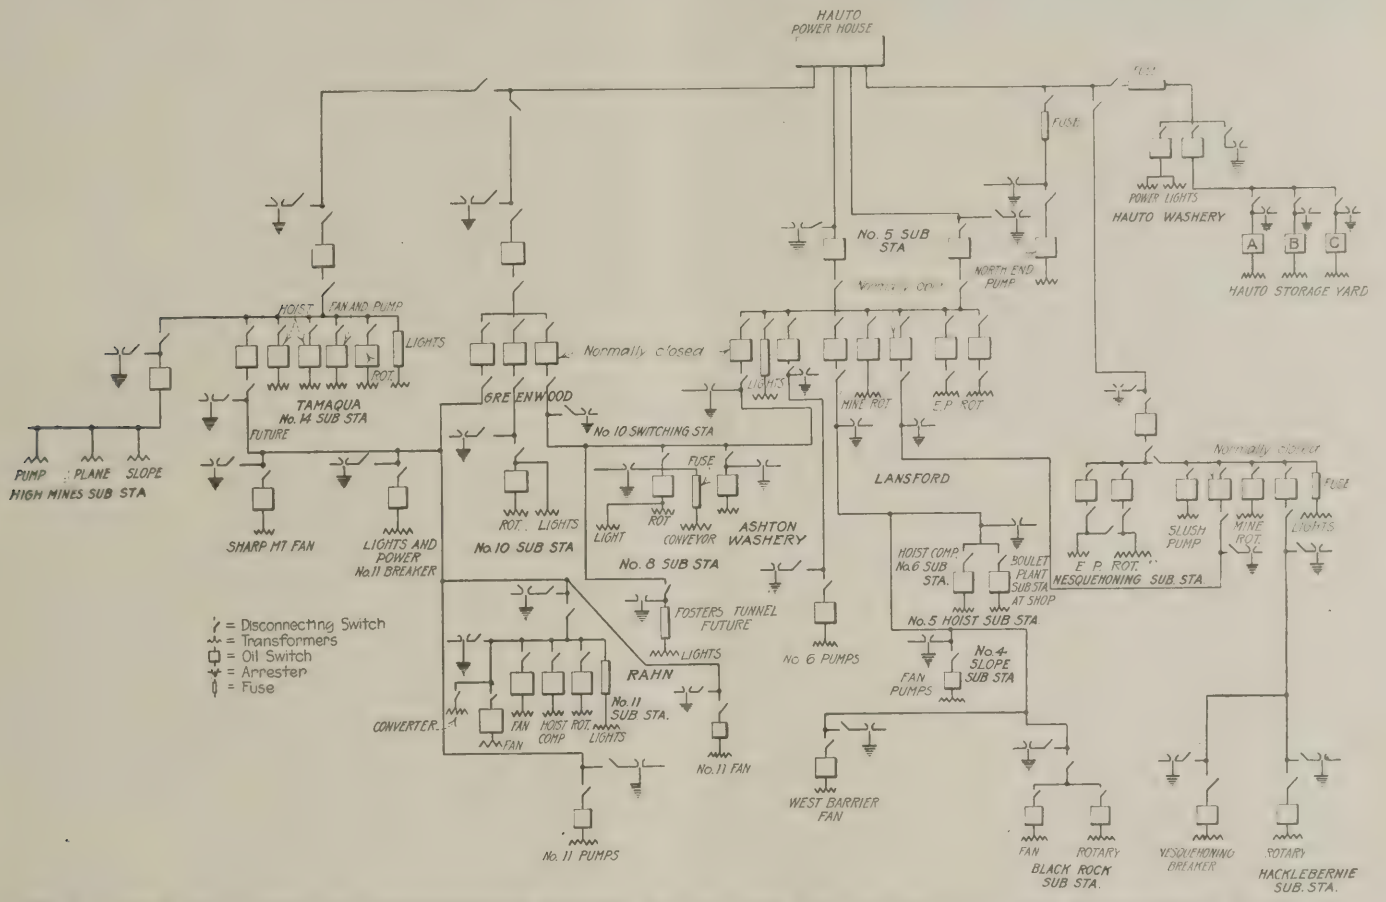

FIG. 2. PLAN OF 11,000-VOLT DISTRIBUTION SYSTEM FOR PLANTS OF LEHIGH COAL AND NAVIGATION COMPANY

copper tubing with an outside diameter of $\frac{15}{16}$ in. and an inside diameter of $\frac{11}{16}$ in. There are two sets of disconnecting switches, so that power can be cut off both sides of the oil circuit breakers to permit of making repairs and inspection. These incoming lines are equipped with necessary current transformers (Fig. 3), which are used in connection with the trip coils of oil circuit breakers and the instruments (ammeters and wattmeters) mounted on the switchboard. In the bus between the two incoming line connections and connections for feeders are mounted the current transformers used in connection with watthour-meters which measure the power delivered to the substation. From this bus are supplied, through the disconnecting switches and oil circuit breakers, a bank of three (500 kv.-a. each) oil-cooled transformers, 11,000 to 2300 volts, and a bank of three (110 kv.-a. each) oil-cooled transformers, 11,000 to 172 volts, all the transformers being of Allis-Chalmers manufacture.

secondary or 2300-volt lines from the transformers through suitable disconnecting switches and oil circuit breakers to a 2300-volt bus, from which taps are taken through disconnecting switches and oil circuit breakers to the lines, which extend to the hoists. Each hoist has its independent line and equipment.

The 172-volt transformers (noted above) are used to supply the alternating-current power to the rotary converter (Fig. 4). This is done by extending taps from transformers through disconnecting switches to three-pole, double-throw knife-switches, to the converter. The direct current is taken from the converter through a single-throw, single-pole knife-switch to a suitable carbon break circuit breaker to a 275-volt bus. From this bus a tap is taken through a carbon break circuit breaker to necessary switches to a feeder which extends down the shaft to furnish power to the haulage system, car hauls, transformers and so on.

The switchboard, which was furnished by the West-

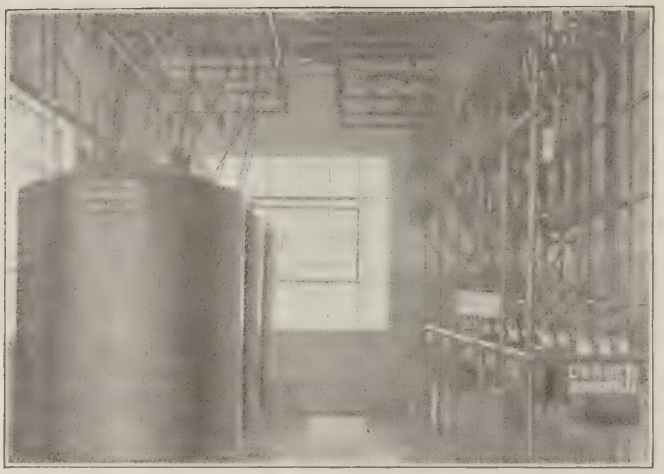

FIG. 3. THE TRANSFORMERS AND MODERN WIRING ARRANGEMENTS AT TAMAQUA SUBSTATION

inghouse Electric and Manufacturing Co., is made up in two sections—one of ten panels and the other of nine panels respectively. The nine-panel board is used to control panels Nos. 1 and 2, the two incoming lines; panels Nos. 3 and 4, the present bank of kilovolt-ampere transformers, 11,000-volt side and future bank of 500 kv.-a.; panels Nos. 5 and 6, control 2300-volt side of transformers; panel No. 7, controls power to water hoist; panel No. 8, controls power supply to a future coal hoist; and panel No. 9, controls power to the present tender hoist. There is a panel at the end of this nine-panel board which was installed by the power company, on which is mounted all metering equipment for measuring the power supplied to the substation.

The ten-panel switchboard is used to control panels Nos. 1 and 2, control 11,000-volt side of present rotary converter transformers and also future converter transformers; panel No. 3, controls the future high-tension side of 440-volt transformers; panels Nos. 4 and 5, to control future 440-volt equipment; panels Nos. 5 and 6, to control the 172-volt side of present and future rotary transformers as well as the alternating-current side of converters; panels Nos. 7 and 8, to control the direct-current side of present and future converters; and panels Nos. 9 and 10, to control the present direct-current feeder with the possibility of an additional feeder being installed at some future time.

In these substations, the copper tubing and pipe-frame mounting of equipment permit of open construction whereby everything is accessible. It is only the low-tension wires which run in fiber conduits in the floor. The electrical machinery and apparatus were furnished by the leading manufacturers in these lines.

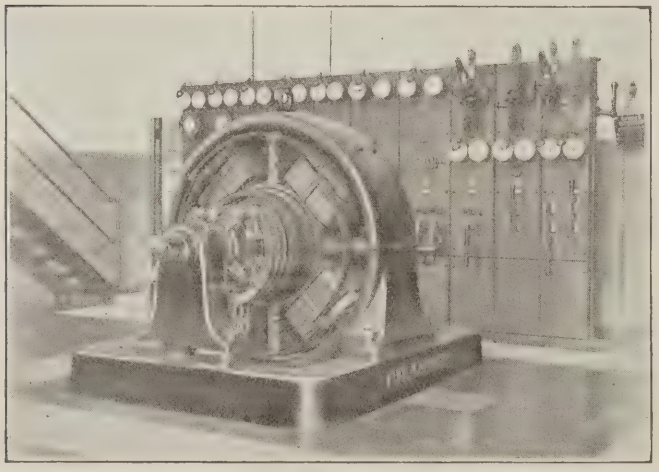

FIG. 4. ROTARY CONVERTER AND SWITCHBOARD AT TAMAQUA SUBSTATION

Direct-current rotary converters are used for supplying power for mine haulage, which includes 95 miles of trolley wire and 88 locomotives of various types and sizes. Alternating current is supplied to mine fans, pumps, hoists, air compressors and breaker machinery. Every breaker, pumping station, individual fan and hoist is metered so that information is obtainable as to the amount of power consumed by each individual class of equipment. All meters are read monthly and a close check is kept on the way power is used in haulage, pumping, ventilation and in the breakers. Thus the cost of power per ton of coal is distributed among the various items entering into the expense of production.

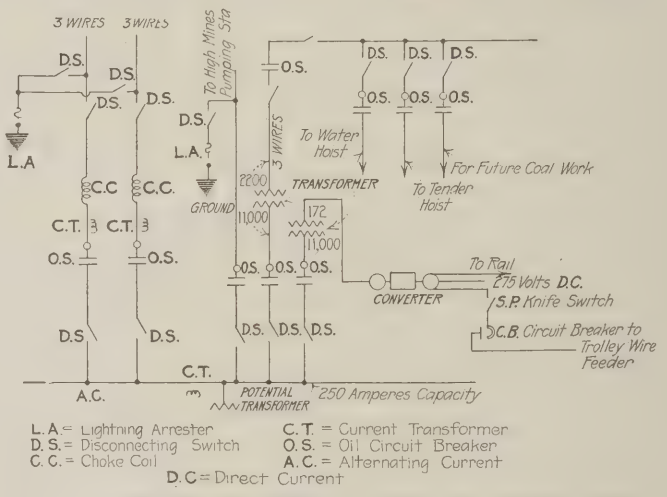

FIG. 5. WIRING DIAGRAM AT TAMAQUA SUBSTATION

When sufficient data have been secured to make the information reliable for reference under every condition likely to be met with in operation, valuable standards will be established. Leakage due to many causes encountered in practice then will be the more readily detected.

Gives $300,000 for Engineering Research

Ambrose Swasey, of Cleveland, Ohio, has recently given the Engineering Foundation an additional $100,000 for the endowment of engineering research. In 1915 he gave $200,000 for this purpose, so that his total gifts are now $300,000. Mr. Swasey's original gift made possible the establishment of the Engineering Foundation by the United Engineering Society, representing the American Society of Civil Engineers, American Institute of Mining Engineers, American Society of Mechanical Engineers and American Institute of Electrical Engineers.

Mr. Swasey is a past-president of the American Society of Mechanical Engineers and is well known as a designer and builder of large telescopes, other optical instruments and fine machine tools. His gifts have been inspired by his conviction as to the necessity for research in engineering sciences, in connection with the war, and in keeping the United States of America in the forefront of the nations in industrial development in the new peace era.

Research and Progress in Byproduct Coking in Great Britain—I

By J. B. C. KERSHAW
Colwyn Bay, Liverpool, England

SYNOPSIS—*The series of articles of which this is the first deals particularly with conditions in Great Britain. Much progress has been made, chiefly in heat control, but also in the recovery of various byproducts. Costs of byproduct recovery have likewise been somewhat reduced.*

AUG. 4, 1918, marked the entry of the European war upon its fifth year, and with no prospect of an early decision the demand for war materials and stores of all kinds is increasing month by month. Especially is this true in the case of explosives. For as the world struggle continues, the urgent call of the army and navy authorities in all countries engaged is for more and yet more explosives.

In an article published in *Coal Age* for Nov. 24, 1917, I gave a diagram showing the various products obtained in the byproduct coking industry, and the connection of this industry with the manufacture of explosives. Figures were also given showing the expansion of byproduct coking in the United Kingdom, in the years 1907 to 1915, the increase of the byproduct coke production during this period being from 18 to 50 per cent. of the total amount produced. The enormous demand for benzol and toluol for explosives manufacture has of course accelerated the movement in favor of byproduct coking both in the United States and the United Kingdom, and it is probable that over 60 per cent. of the coal coked in the latter country is now treated in byproduct ovens.

As regards America, the latest reliable figures show that the capacity of the byproduct coke ovens has doubled in the last three years, and that the output of light oils has increased from 7,500,000 gal. in 1914 to between 40,000,000 and 60,000,000 gal. in 1918, with a corresponding increase in the yield of toluol. The number of byproduct recovery ovens has increased from 6500 in 1915 to 12,000 in 1918 (when all the present building contracts are completed), and the carbonizing capacity of these ovens, which was 24,000,000 tons of coal per annum in 1915, is now said to be 60,000,000 tons.

In view of these striking figures proving the remarkably rapid growth of the byproduct coking industry, it is thought that some notes upon the recent work and progress in the United Kingdom may prove of value to American readers. American practice no doubt is ahead of English in the size of units and plants, in the use of mixed fuels, and in the higher temperatures employed in carbonization. On the other hand, English practice is superior to American in the completeness and more scientific control of the recovery processes. Coke-oven managers in each country therefore have something to learn from "over the water."

In the present series of articles the following subjects will be dealt with: Modern theories of the carbonization process; the path of the coke-oven gases; modern coking practice in the United Kingdom and a comparison of early and modern practice; tar distillation plant and its problems; benzol recovery and distillation plant; the utilization of waste gases from coke-ovens; the future development of the industry.

A paper read last year before the Western Section of the newly formed British Coke-Oven Managers' Association by D. V. Hollingsworth discussed at considerable length the results of the latest research work upon the constitution and composition of coal, and the occurrences in coke-ovens during carbonization. Since coking practice in the past, both in Britain and America, has suffered from being founded entirely upon empirical rules and principles, the paper is worth the attention of all coke-oven managers and engineers.

Summarizing the research work carried out in recent years in the United Kingdom by Aitkin, Bedson, Lomax and Wheeler, the author stated that:

> The microscopic work of Lomax, of Pendlebury, and Aitkin, of Glasgow, has clearly shown that the substance of coal may be divided into three main parts: (a) An opaque black substance (probably granular or amorphous). (b) A yellow or reddish substance (soluble in turpentine). (c) An earthy substance, like umber. These different parts are clearly distinguishable when coals are cut into very thin sections.
>
> Professor Bedson, of Newcastle, has demonstrated that it is possible to divide coals into three parts by the use of different solvents. It has been found that one portion of coal is completely insoluble in pyridine; another portion is soluble in pyridine, but not in chloroform: while a third portion is soluble in both pyridine and chloroform. It is considered that the substance insoluble in pyridine represents stable humic matter, produced through the destruction of the cellulose portion of vegetation, and that the part soluble in both pyridine and chloroform is of a resinous nature, and results from the decay of the natural resin, well known to exist in living vegetation.
>
> The report of the Home Office on "Coal-Dust Explosions" contains Wheeler's results of experiments on heating coal in various ways, whereby it is shown that coal contains at least two different classes of organic compounds, namely: (a) A part which breaks up at between 400 deg. and 700 deg. C., and yields principally paraffin hydrocarbons, but little hydrogen; and (b) a part which requires a temperature of above 700 deg. C. to effect its decomposition, and yields principally hydrogen.
>
> It would therefore seem that there is a definite connection between the results of these experimenters, which together establish the opinion that coal is composed of at least two different types of substances. Further, it has been established that it is the resinous portion of coal which produces its caking or fusing properties, because on carbonization it first breaks up to a pitchy residue, which causes the particles of true coke to become agglomerated together. This resinous matter is easily oxidized by exposure to air, and when oxidized the coal will no longer produce an adhesive coke.

The author then discussed the effects of heat upon coal, and pointed out that the rapid changes which occur

in the coke ovens are somewhat analogous to the slow changes which Nature has produced in the past, during the conversion of dead and decaying vegetation into coal.

It must not be supposed that under the influence of heat coal breaks down straight away to the products which are drawn from the oven. Intermediate products of different degrees of complexity are formed, which suffer further decomposition, or maybe themselves react with each other to form new compounds. Nor must it be inferred that there is any accident about the formation of these substances. Without doubt the reactions occurring in the oven during carbonization of coal are all in accordance with well-known laws, and it should be the duty of those in charge of such processes to learn what these laws are, in order the better to control them.

The influence of the iron impurities present in coal upon the coking results was next dealt with, and the reason for the advantages gained by the removal of pyrites and the addition of lime to the fuel were scientifically explained. The effects of increased temperature upon the yields of gas, light oils and pitch, and of moisture upon the yield of ammonia, were also examined, and the figures contained in Tables I and II were given to illustrate this portion of the paper.

TABLE I. INFLUENCE OF TEMPERATURE UPON YIELDS OF GAS, LIGHT OILS AND PITCH (HOLLINGSWORTH)

Temperature, Deg. C.	Gas Made, Cu.Ft. per Ton	Light Oils from Tar, per Cent	Pitch from Tar, per Cent.
500	6,600	19.67	28.89
600	7,200	16.51	33.80
700	8,900	8.20	41.80
900	10,162	0.445	64.08

TABLE II. INFLUENCE OF TEMPERATURE UPON YIELD OF AMMONIA (HOLLINGSWORTH)

Temperature, Deg. C.	Nitrogen in Coke	Nitrogen as Ammonia	Nitrogen in Gas	Nitogen in Tar, Etc.
600	72.4	10.6	5.13	11.87
700	70.1	19.6	7.98	2.32
800	65.2	21.7	9.43	3.67
900	62.1	20.8	15.61	1.49

The paper concludes with some practical suggestions, and as these represent a combination of advanced English theory and practice, they may well be summarized:

1. The sulphur and ash in the fuel charged should be reduced to the lowest possible percentage, by careful picking and scientific control of the washing plant.

2. The moisture permitted to remain in the coal, after washing, should be as near 9 per cent. as possible.

3. The temperatures of the ovens should be raised or lowered *en masse*, and not individually; tampering with the heats as between one shift and another should not be permitted, and the effect of darkness in rendering more conspicuous the heat of the flues should be discounted.

4. The damper should not be adjusted by anyone save the plant manager, and the two extremes of damper position should be avoided. A too high damper means "loss" of heat in the chimney; a too low damper "smothering" the heat in the flues. The lowest damper position consistent with a clear atmosphere in the flues is the one to be aimed at, and a sufficiently well spread-out flame to prevent local heating of the ovens should be obtained.

5. The ovens should be filled with even level charges, and there should be no "humps" on the bench side of the compressed charge. A "make up" car of slack should never be omitted, as the vacant space caused by the falling of the front end of the cake leads to thermal decomposition of the evolved gases.

6. The ovens should be discharged in regular order, and to insure this regularity a chart should be devised allowing the maximum time between the discharge of adjacent ovens.

As regards the speed of the removal of the gaseous products, the author stated that this was one of the most important features of good management, and one that ought always to be under perfect control. He recommended therefore:

1. Regular and proper cooling of the gases, whereby the exhausters have a uniform bulk of gas to deal with.

2. Keeping thoroughly clean the ascension pipes and mains, and especially the valves. This last is insured by the use of a chart, indicating when valves were last dismantled and cleaned.

3. The use of properly acting main governors.

4. Proper leveling of the charge to prevent back pressure.

5. Keeping such a vacuum in the mains as will leave only slight pressure on the oven when at its maximum output.

Finally, he urged that for the more efficient and scientific control of the coking process some means of measuring the volume and testing the thermal value of the evolved gas was necessary; and for this purpose he recommended the installation of meters and recording gas calorimeters. With this combination of apparatus, the coke-oven manager would be warned at once when any departure from normal working had occurred, and he could then take whatever steps were necessary to restore the conditions that had been temporarily upset.

Another contribution to the theory of carbonization that is worthy the attention of American coke-oven managers is an article by G. E. Foxwell, which appeared in *The Gas World* of Dec. 1. 1917. In this the author cites experiments carried out by himself to prove that in coke ovens the path of travel of the evolved gases is not, as generally assumed, up the interior or center of the mass of half-coked fuel, but is up the outside of the charge. The gases therefore must come into intimate contact with the heated coke and with the walls of the oven; and as it is proved that heated brickwork has a catalytic action upon gases, and is therefore more effective in producing decomposition than radiant heat, the greater number of secondary reactions will occur in this outer area of the oven. The following paragraphs contain the gist of this important article:

The actual temperature at which a coal decomposes—that is, at which the primary products of distillation are evolved—is probably nearly the same (within narrow limits) for all coals and in all ovens. Differences in yield due to varying oven temperatures are simply caused by the different temperatures at which the gaseous products are "fixed." This "fixing" consists essentially in setting up a condition of equilibrium between the various gases present, and is brought about by contact with the red-hot coke and oven walls. There is probably an optimum temperature for the formation of each particular byproduct, and it is only by a careful experimental study of the reactions taking place in the coke oven that any real light can be thrown on the matter.

These considerations open the way to a further wide field for research. The writer has shown that the products of distillation come in contact with the oven walls, and that hence the temperature to which they are subjected is under control. It has been mentioned that heated firebrick exerts a catalytic influence on the gases evolved. It follows, therefore, that if found advantageous the catalytic influence

may also be brought under control. Thus there may be found to be a radical difference between the products formed and yields obtained when the walls are made of silica bricks, as compared with those obtained with fire-clay bricks. Again, lime-bound silica bricks may give results which differ from clay-bound silica bricks. Bauxite, magnesite, etc., are all worthy of trial. Further, by treating the bricks with small quantities of the rarer oxides, metals, etc., the ammonia yield may be increased and the character of the tar modified.

It may also be noted that this has an influence on the salt problem, for since most of the gases come in contact with the wall of the coke oven, practically the whole of the salt volatilized during the coking of the coal will also come in contact with the walls. On this theory it is readily understandable why such a relatively small amount of salt is able to cause so much corrosion.

Modern Coking Practice in England, and a Comparison of Modern and Early Methods

The coke-oven byproduct plant erected at Marley Hill, County Durham, for John Bowes & Co. is typical of the modern English coking plant, and may therefore be described before contrasting modern with early methods. The plant is supplied with coal from the surrounding collieries in a fine state of subdivision (95 per cent. of the deliveries passing through a ½-in. screen and 60 per cent. through a ¼-in. screen) and containing 15 per cent. dirt.

The coal as received is first passed through a Blackett washery, by which the dirt content is reduced to about 3 per cent., and the washed and drained coal is then compressed and charged into the ovens in the usual manner. The coke produced is of average quality and contains about 8 per cent. ash. The gas is conveyed from the ovens by cast-iron pipes and is passed through air and water coolers, and the tar removed before passing through the exhausters.

The compression it here receives raises the temperature, and the gas is passed through another cooling tower before reaching the scrubbers which remove ammonia and benzol. A portion of the scrubbed gas is of course used for heating the ovens, but the surplus gas and waste heat is employed to generate steam, which is used in the coking and byproduct plants and also for operating a 600-kw. turbo-generator, by aid of which all the mechanical work of the coking and recovery plant is carried out.

The ammoniacal liquor obtained from the first scrubbers is used to produce gray sulphate of ammonia by the Wilton process, or to produce a concentrated ammonia liquor of any desired strength by the Diamond process. The benzol recovered from the gas by the usual method of washing with creosote oil is treated in the special distillation portion of the recovery plant, and separated into 90 per cent. benzol, 90 per cent. toluol and 90 per cent. solvent naphtha.

The naphthalene is conveyed to the tar distillery and is treated with the tar produced from the coking plant in four pot-type tar stills, in order to separate the naphtha, creosote, naphthalene and anthracene from the residue of pitch. A sulphuric acid plant of the Moritz type is now being erected in order to complete this well-equipped byproduct coke-oven plant.

W. Diamond, who is the manager of this plant, is also chairman of the Northern Section of the Coke-Oven Managers' Association, and in a paper read before a recent meeting of the members he contrasted early and modern methods of coking in this district. The tar produced in gas manufacture 25 years ago, from the same coals used today, was quite different in character, both physically and chemically, being more fluid and richer in naphtha and phenols, while the pitch did not contain so much free carbon.

Today, the tar produced by the higher heats generally used consists chiefly of naphthalene, with a little anthracene oil and pitch. The higher temperatures also lead to some decomposition or cracking of the benzol and other light oils before they leave the retorts or ovens. Comparing the yields of ammonia, he had not noted so much difference between the results of the past and present. The coke produced, however, by the lower temperatures used for carbonizing in the past, was much larger in size, was tougher, and produced considerably less breeze. Summarizing these results we have the following contrast:

> To sum up all these results, we produced in the first case a coke having better physical properties, consequently we produced more benzol, more tar, and the same proportion of ammonia, but one-sixth less volume of gas. In order to produce the same quantities of these, our oven installations would require to be one-third larger. This would mean a considerably increased capital charge, while the only profit to compensate us would be on the benzol, tar and ammonia.
>
> There is one other drawback to low-temperature distillation, and that is in the quality of the benzol produced. It is common knowledge that when coal is distilled with lower temperatures large yields have been found and classified as benzols, but have turned out to contain considerable quantities of paraffins—so much so, that for some purposes the paraffins have spoiled the toluol to a certain extent, by making it most difficult, and not at all profitable, to manipulate chemically.

Another authority upon English coke-oven practice, G. Blake Walker, has recently contributed a paper to the Institute of Civil Engineers upon "Recent Developments in Byproduct Coking," which is worth attention. The author states that since his paper of 1900, a complete revolution has occurred in English coking practice and that no ovens of the beehive type are now being built. The three most noticeable improvements in modern plants are: (1) Better distribution and heating of the combustible gases, so as to insure a more equal temperature in all parts of the oven walls. (2) Separate supply of air for combustion to all the numerous burners. (3) "Direct" recovery of sulphate of ammonia.

After referring to the use of the surplus gas for various heat and power purposes, and to the great importance of the benzol, tar and ammonia since the war had cut off our supplies of German dyes, drugs and fertilizers, the author pointed out that the objects to which all recent improvements are directed are the following: (1) More intense and better equalization of heat in all parts of the oven walls, in order to burn off the charge more quickly and uniformly. (2) Equalization of the pressure of the gas between the ovens and the heating flues. (3) Reduction in the time of coking, whereby a larger output of surplus gas, coke and byproducts is obtained from a given number of ovens, and reduction in the cost of coke making, etc. (4) Good means of inspection of the heating flues. (5) Facility of regulation. (6) Increased yield of ammonia and benzol. (7) Reduction of quantity of gas required for heating the ovens, by the use of regenerators.

The paper closes with an analysis and comparison of the costs of operating the direct, semi-direct and indirect processes of ammonia and benzol recovery, based on figures given in recent contributions by Christopher and Heck. Although these figures are drawn from entirely different sources and relate, the first set to English, and the second set to German practice, they show fairly concordant results which may be summarized as follows:

COMPARATIVE COST OF AMMONIA AND BENZOL RECOVERY BY VARIOUS SYSTEMS, IN PER CENT.

	Old System	Semi-Direct System	Direct System
English results	157	108	100
German results	131	114	100

The direct system of recovery is therefore far more economical than the old indirect or semi-direct system, but, as the author points out, the costs will differ in nearly every case, owing to local circumstances, the efficiency of operation of the plant, and the proportion of gas being treated.

(To be continued)

Diamond Drilling Near Chemainus, B. C.

New coal-mine development of an important character has commenced on Vancouver Island, British Columbia. The measures known to exist on the East Coast near the town of Chemainus are being explored by means of diamond drill, and those in the best position to hazard a forecast do not hesitate to predict that the results will be satisfactory as far as the quality and quantity of the coal, the existence of which is to be definitely established, is concerned. H. W. Treat, of Seattle, Wash., is the party best known in connection with these steps to develop this latent natural resource, but, according to newspaper statements and common report, he has behind him the capital of the Samuel Hill interests of the United States. If this is so it is generally believed that the coal industry of this section is likely, in the near future, to experience a very material growth.

The drills in question are being sunk near the foreshore at Chemainus, at which point Mr. Treat has secured some Provincial leases and options on some Crown Granted Lands. Incidentally, Mr. Treat, whose energies have been devoted to the Island for some months, has obtained options on other coal-bearing lands of the district. But in this particular section the drilling is being pushed forward expeditiously under the supervision of John Hamilton, who had charge of similar work for the Granby Consolidated Mining and Smelting Co. when that company was opening its coal mines at Cassidy's, Vancouver Island. The prospects for the establishment of another large colliery in this part of British Columbia, therefore, are bright, and residents are looking forward to it with gratification.

An account of what led up to the present situation is interesting. When the Esquimault & Nanaimo Railway Co. obtained its land grant as a subsidy for the construction of the road, the Dominion Government, besides giving it all the mineral rights within the limits of the belt with the exception of that of gold and silver, also gave it the right to mine "in and under the seas." The Government, however, was doubtful, apparently, as to whether it had the power to extend any such exclusive privilege to any company or individual. For that reason, the qualification was inserted that this applied only if Parliament had the authority necessary under the British North America Act.

This was the position when Mr. Treat and his associates cast their eyes on the East Coast foreshores of Vancouver Island and visualized the immense deposits of coal which lay beneath the protected waters of its bays and estuaries. With the demand for coal the world over increasing, and the price soaring, it was decided that the point as to whether these rights were open or whether they were the exclusive property of any one company by virtue of Act of Parliament should be brought to an issue. As was anticipated, no doubt, the plans of Mr. Treat had not proceeded far before legal proceedings were instituted, and since then, up to a short time ago, the matter has been before the courts of the land.

The result, as may be judged by the fact that development operations are proceeding, was that the position that the Esquimault & Nanaimo Railway Co. cannot claim exclusive foreshore privileges has been upheld, although it is not improbable that the litigation will be carried as far as the Privy Council, as the dispute is one of the highest importance, involving title, if the opinion of geologists is to be given any credence, to considerable coal deposits. It is possible to get some idea of the coal wealth of the foreshores of the east coast of Vancouver Island, from Cowichan Bay to Nanaimo, a distance of between forty and fifty miles, and even further north, by contemplating the property of the Canadian Western Fuel Co. at Nanaimo, and its production. This company's chief output comes from No. 1 Mine, and its workings are under water. It acquired title to this, before the railway company got its land grant, from the Hudson's Bay Co., which, of course, was the pioneer in the opening up of Western Canada, as it was in the exploitation of the natural wealth of the whole of the Dominion of Canada.

Ventilation After Mine Explosion

In the event of the ventilating fan or appliances having been injured, wrecked, or destroyed by the force of an explosion immediate attention should be given to the repairs necessary for reëstablishing the ventilating current. In a drift or slope mine, advantage should be taken of any natural ventilation that has become established. In a shaft mine advantage should be taken of any natural ventilation in exploring on the intake current, especially on ladders and stairways in any shaft through which such natural ventilation is supplying fresh air. Men may be found alive on the stairways. To aid natural ventilation or to establish a current of air in the absence of such ventilation, a spray of water may be directed down one of the shafts to cool the air and cause the shaft to become an intake. On the upcast air compartment a steam jet may be installed to heat the air. The jet should always be placed in the compartment of the shaft in which there are steam pipes, as the heat from the pipes will assist in warming the air and help to make an uptake current.—*Rescue and Recovery Operations in Mines.*

Increasing Coal Mine Efficiency—IV

By CHARLES E. STUART
United States Fuel Administration, Washington, D. C.

SYNOPSIS—*This article is devoted to the efficient electrification of a coal mine using purchased power. In many cases, aside from securing current at a less cost per unit than that for which it can be generated, purchasing current has the advantage of putting its cost visibly on the cost sheet. Care exercised in changing over from one source of energy to the other is care well spent, as many economies can usually be made.*

WHILE central station power is not available at the present time in many coal fields except through increasing the demands on stations already connected up, there are other coal fields where there is a considerable surplus of capacity. In either case I believe that the following description will be of some value. It may offer suggestions to mines now fairly well equipped. It should certainly prove timely to operations that are increasing their equipment or electrifying new developments.

Considerably over half of the coal produced today is mined with the aid of purchased power. Take the Pocahontas fields of West Virginia, for example. The Appalachian Power Co. began to cover this field with its transmission system in 1911. Today half of the coal of the field is mined with power from this source: another 20 per cent. is mined with power generated in the central station of the United States Coal and Coke Co.

FIG. 25. TYPE OF TRANSFORMER STRUCTURE EMPLOYED

FIG. 26. ROTARY CONVERTER IN UNDERGROUND SUBSTATION

The remaining 30 per cent. is mined with the aid of isolated plants, nearly all of which were installed prior to the development of the system of the Appalachian Power Company.

The considerations in favor of purchased as against manufactured power may be briefly stated as follows: The elimination of the supervision necessary to properly operate and maintain a power station; elimination of skilled and semi-skilled labor, such as engineers and firemen, and the conservation of fuel attendant upon purchased power. A series of tests in the Pocahontas coal field (and these tests represent a pretty fair average) show that 11.6 lb. of coal are consumed for each kilowatt-hour generated. A central station making power in that field will operate at about 2½ lb. of coal per kilowatt-hour. A saving of approximately 9 lb. of coal for each kilowatt-hour used, or an average of 9.1 lb. of coal for each ton mined is thus possible.

In the anthracite fields of Pennsylvania, the estimate of coal consumed per kilowatt-hour is 16 to 17 lb. In this case, and for the purpose of the estimate, steam used for fan drive, pumps, etc., has been converted into the electrical unit. In fact, it is estimated in the anthracite field that a production of 90,000,000 tons of coal represents at least 9 000,000 tons of coal burned to produce power for this tonnage output. Central station electrification of this field would mean a saving of approximately 8,000,000 tons as now required in the production of energy for mining.

A summary of comparison made in the Pocahontas coal field shows 3 kw.-hr. consumed per ton of coal produced for purchased power and 5.8 kw.-hr. consumption per ton for manufactured power. This saving is the result of the elimination of line losses through placing the converting stations at the load center, by utilizing two-speed fan motors and by the practice of economy which invariably follows where the direct relationship between power consumption and monthly cost can be observed.

With purchased power it is possible to use alternating current motors for nearly all stationary-motor

work. These motors are extremely reliable, and they require little or no attention except occasional oiling of the bearings. They represent the ideal stationary motor for the mine, being as nearly foolproof in construction as it is possible to build. As a rule purchased power is less costly than manufactured power. This, however, is not always the case. There are numerous varying factors governing this consideration.

Before going into a description of a specific installation it should be stated that it was the intention of the mine owner, the engineer and of the power company to spare no reasonable expense in order to make this installation efficient. I will first give a general description of the layout of the plant before purchasing power, and then show just what methods were adopted for the use of purchased energy.

The main power plant consisted of two 150-kw., 275-volt, direct-current General Electric generators direct connected to Harrisburg slide valve engines. From the main power plant distributing lines were run out at 250 volts direct current, to supply the mine, fan, tipple, pumps, shops, lights and miscellaneous power used. The greatest distance from the power plant to the back of the lease was approximately 3 miles. This necessitated the use of heavy copper extending into the mine 2½ miles. Even then the voltage on the 250-volt circuit well back in the mine was as low as 150 volts with heavy pulling.

The fan was located at the drift mouth, 1500 yd. from the main power plant and was supplied over a 2/0 circuit. The voltage delivered at the fan motor was as low as 200 when the load was pulling heavy. The fan was driven by a 75-kw. Westinghouse direct-current generator running as a motor.

The tipple was driven by ten motors aggregating 335 hp., varying in size from 75 hp. to 7½ hp. and controlled from three different points on different landings. As all of this apparatus was operated by one man it was necessary for him to go from place to place in starting up the tipple and to climb up and down many steps. All wiring was of the open type run on knobs and through tubes, while in many cases it lay on steel girders. Tests were made on each motor separately in order to see if any power demand could be eliminated. While these tests showed that in several cases machines were over-horsepowered, still it was deemed advisable on account of the cold weather conditions not to change

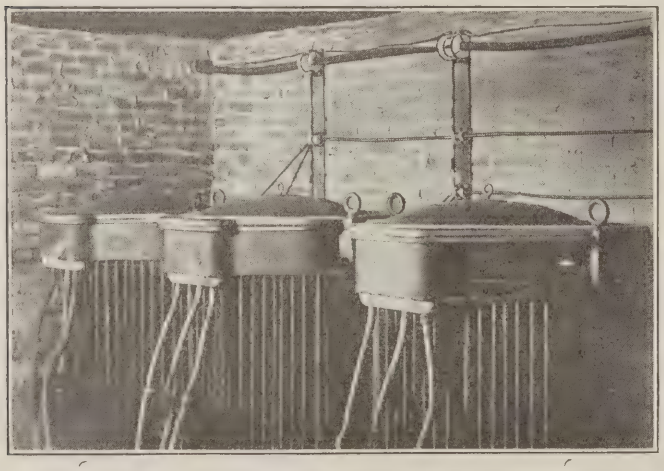

FIG. 27. TRANSFORMERS EMPLOYED UNDERGROUND

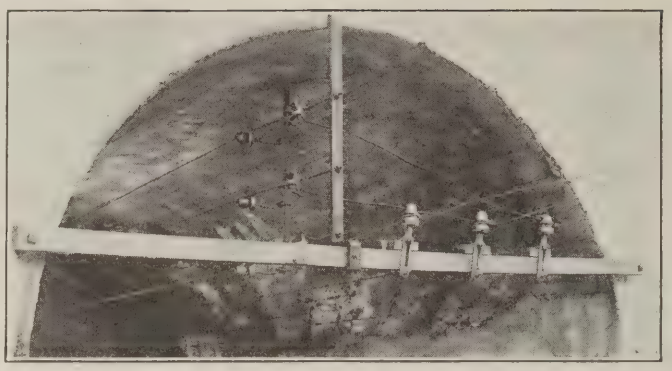

FIG. 28. METHOD OF SUSPENDING ELECTRIC LINE IN THE AIR COURSE

any of the sizes of the motors. The lowest potential recorded during this test was 200 volts. The tipple was fed by two 4/0 circuits.

The deep well pump was driven by a 10-hp., 250-volt, direct-current motor and was supplied from the circuit feeding the tipple, being about 100 ft. therefrom. The speed of this motor was varied by means of resistance, and in this way it was possible to pump just enough water to meet the requirements, without continually overflowing the tanks.

The machine shop was driven by a 10-hp., 250-volt, direct-current motor driving line shafting from which the various machines such as air compressor, lathe, drill press, boring machine and the like, were driven.

The lights were fed from a three-wire circuit, controlled by three single-pole knife switches, using the middle wire as a common return for the two outside wires, and maintaining a day and night circuit. Thus, by pulling one of the outside switches, the night circuit could be killed, or, vice versa, the day circuit could be switched on. All miscellaneous power such as refrigerator, motor for store, general manager's house meat choppers, etc., were supplied from the day circuit.

New Equipment for Purchased Power

I will now give a brief description of the general layout adopted. As shown at the beginning, the losses were considerable by the time the current reached to the most remote point in the mine from the main power plant. In order to keep the losses at a minimum, it was decided that two substations should be installed, one in the existing power plant and one inside the mine. A description of each is given separately under "Outside Substation" and "Inside Substation," later on in this article. In order to meet the situation most effectively it was decided to adopt two different voltages—that is, to install two banks of transformers. The type of transformer structures used is shown in Fig. 25. In describing the transformer stations I will designate them as bank No. 1 and bank No. 2.

Bank No. 1 consists of three, 100-kv.-a. 13,200/440-volt transformers located approximately 50 ft. from the tipple. From the secondary buses of these transformers a three-phase, 440-volt line runs to a main feeder panel in the tipple, and three of the two-circuit 4/0 feeder wires leading from the main power plant to the tipple were converted into a three-phase, 440-volt circuit leading to the outside substation located in the main power plant. The current is measured on the secondary side of the transformers, the coal company having a check

meter installed, as well as a meter on tipple circuit and pump, outside substation and lights and shop, thereby giving a correct proportion of the power chargeable to each installation.

Bank No. 2 consists of three 75 kv.-a., 13,200/2300-volt transformers located at the drift mouth. From the secondary buses of these transformers a 2300-volt, three-phase line runs into the fanhouse, tapping a three-phase bus, from which a circuit is fed through 2300-volt disconnecting switches to the fan and through 2300-volt disconnecting switches and a 2300-volt time-limit, overload, no-voltage release oil switch to the line running to the inside substation. The current is measured from buses in the fanhouse, the coal company having a check meter, as well as a meter on the fan circuit.

Outside Substation—The outside substation consists of a 150-kw., 250-volt, direct-current, six-phase, 1200-r.p.m., Westinghouse rotary converter with three single-phase transformers from 440 to rotary voltage, and a switchboard containing all necessary starting and control apparatus, also one automatic reclosing direct-current circuit breaker, thereby eliminating a constant attendant in the substation. In addition to the direct-current feeder for the mine circuit, there is a separate direct-current feeder for the larry circuit and boom hoist located in the tipple and controlled through circuit breakers and single-pole knife switches. A direct-current meter was installed on the larry circuit showing the kilowatt-hour consumption of the larry.

Description of Inside Substation

Inside Substation—Before describing the electrical apparatus for the inside substation, I should like to give a brief description of the location and character of the room built to house the necessary apparatus. After having selected the space for this substation, which was in a breakthrough between air course and main entry, it was necessary to remove a considerable amount of coal and slate in order to get sufficient space for the installation.

The apparatus is installed with a view to being able to move any part without interfering with any other. For instance, it is possible to move the rotary, switchboard or any of the transformers without conflicting with either of the other two. The walls are built of brick, being as thick as the width of a brick on the side walls and the length of a brick on end walls. Next to the main entry a double door of sufficient size was installed to enable removal or replacement of any of the apparatus, and a single door opens into the breakthrough leading into the air course. By means of ventilators located in both doors, it is possible to regulate the amount of air flowing, and in this way the substation is kept cool at all times. From the roof the slate was taken down as far as the sandstone top, and left in this condition. This has thus far given satisfaction, and from all appearances will continue to do so.

The apparatus for this substation consists of a 150-kw., 250-volt, direct-current, six-phase, 1200-r.p.m., General Electric rotary converter, with three single-phase transformers stepping the voltage down from 2300 to rotary voltage and a switchboard containing all necessary starting and control apparatus, also one automatic reclosing direct-current circuit breaker. The inside substation apparatus is shown in Figs. 26 and 27.

When it was decided to install this substation in the mine, estimates were made in order to ascertain if it would be more feasible to put a borehole down through the mountain or run a line through the air course. It was finally decided to adopt the latter. Accordingly a three-phase, 2300-volt line was constructed and run through the air course. The type of construction is shown in Fig. 28. Some anxiety was felt as to how this line would hold up on account of slate falls, but a careful inspection of the air course was made and all loose slate or any that was thought likely to fall was taken down.

This line has been in operation now practically a year and there have been only two interruptions; and these were not of a serious nature. The oil switch located in the fanhouse kicked out, but when closed again the line showed clear. It is therefore believed that small pieces of slate fell, causing a momentary short-circuit. The

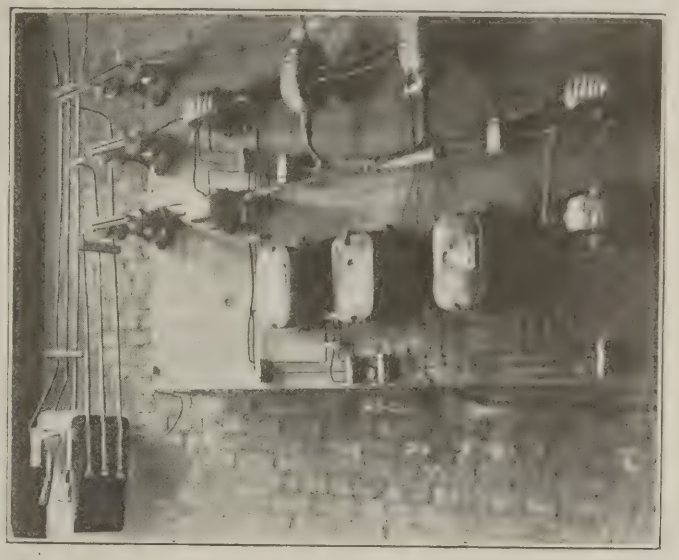

FIG. 29. OIL AND DISCONNECTING SWITCHES IN THE FAN HOUSE

oil switch located in the fanhouse, with disconnecting switches and other apparatus, is shown in Fig. 29.

In place of the 75-kw. generator operating the fan a 100-hp., two-speed, 2300-volt Allis-Chalmers induction motor was installed together with a starting compensator, pole-changing switch, and two sets of overload and no voltage releases, these being of the two-coil type, one to operate on high speed and one to operate on low speed, thereby guaranteeing safety from overloads on both operations. As stated before, there is a separate meter on the fan circuit showing the exact kilowatt-hours chargeable to ventilation.

Special attention is called to the method of control adopted for the tipple. This is shown in Fig. 30. The operator, a one-armed man, has all of his control apparatus located at one central point and arranged so that he can start each machine in its proper order. All wires for the tipple motors were figured and installed of sufficient capacity so that the total drop from the secondary buses of the transformers to the motor would not exceed 5 per cent. All wiring was run in conduit with proper condulets installed on each outlet. Practically all motors were of the slip-ring type, thereby taking care of the heavy starting load, which was a source of nuisance with the direct-current motors, especially in cold weather.

A 10-hp., 440-volt, two-speed induction motor was installed to handle the pump load, thereby enabling a two-speed operation in order to meet the condition, as desired, for this service. A separate meter was installed on this circuit in order to obtain the amount of power chargeable to water supply. A 10-hp., 440-volt induction motor was installed in the shop, driving line shafting to which all operating machines were connected.

The three-wire, 250-volt, direct-current circuit was converted into a three-phase, 440-volt circuit, the two outside legs of this circuit being controlled through circuit breakers and the middle leg through a single-pole knife switch. From this three-phase circuit leading out of the substation 440/110-volt transformers were installed to take care of the lighting and miscellaneous power. These transformers were so located that no secondary lines from the transformers would exceed 500 ft. in length using No. 8 wire for secondaries. There are two single-phase meters installed back of the switchboard on the three-phase, 440-volt circuit for measuring the kilowatt-hours chargeable to lights aud miscellaneous power.

The accompanying figures for purchased power are based on actual records up to June of 1918. The figures for manufactured power are based on 1914 records, allowing for the increase of costs, as incident to present conditions. These figures show a reduction in power cost; also, a reduction in kilowatt-hours consumed. The mine fan, due to the delay in arrival of certain control parts, has never been operated at half speed.

Certain special considerations incident to the application of purchased power arise and require determination. Among these is the question of selection of motor-generator set or rotary converter. Within the last five or six years the 60-cycle rotary converter has been brought to a state of construction perfection where it is one of the most satisfactory and reliable pieces of

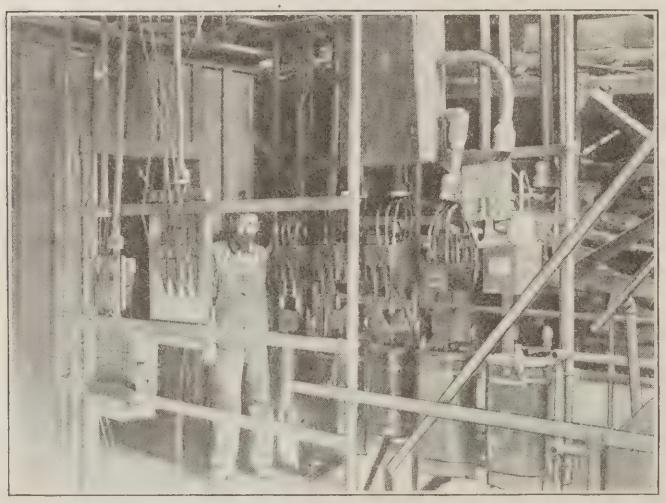

FIG. 30. GROUPED CONTROL APPARATUS IN THE TIPPLE

conversion equipment that can be obtained. This is true whether the case in question is one of operating a single-unit substation, the parallel operation of units in the same substation, or of parallel operation of two or more substations located at different points.

The rotary converter will carry a remarkably heavy overload without flashing. In fact it will readily carry from 100 to 200 per cent. overload on peaks of short duration such as are characteristic of the mine load. Moreover, the operating efficiency is much greater than that of the motor-generator set. Difference in efficiency becomes more pronounced when considered with respect to the low load factor which is characteristic of the mine load. Fig. 31 is designed to compare the efficiency of a 200-kw. motor-generator set with that of a 200-kw. rotary and of a 150-kw. rotary. This particular com-

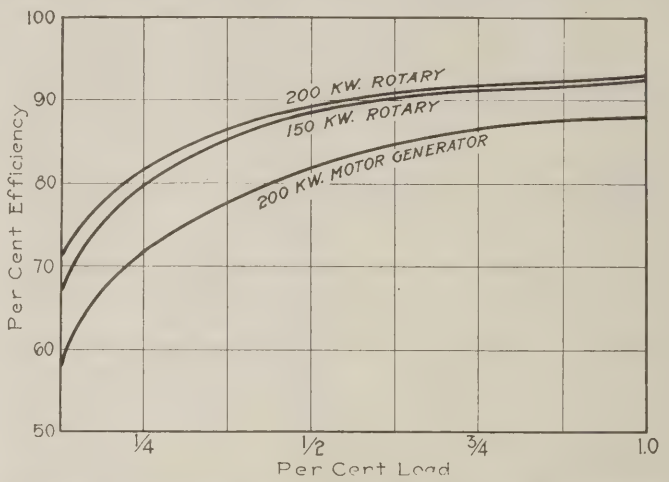

FIG. 31. COMPARATIVE EFFICIENCIES OF TWO ROTARIES AND MOTOR GENERATOR

parison was made for a mine which was using a motor-generator set, but increasing its substation capacity.

Based on the monthly output of the motor-generator set over a period of five months, it was determined that by the installation of a rotary converter and assuming a power cost of 1c. per kw.-hr., the 200-kw. rotary, if substituted, would save $628 per year. The changeover was made in the case referred to, although the motor-generator set had at the time been in opera-

MANUFACTURED POWER (COST)

Power Consumption, 859,209 Kw.-Hr.	Tons Mined, 215,457
Coal 2761 tons @ $2.40	$6,526.40
Engine repairs	807.00
Generator repairs	36.34
Boiler repairs	530.00
Sundry tools	79.74
Supplies from store	58.10
Cost for ash disposal	109.32
Fire insurance and workmen's compensation	420.20
Firemen and engineers	5,047.00
Repairs—labor	518.29
Total	$14,457.39
Superintendence	2,000.00
Depreciation	844.12
Total	$17,301.51
Cost per kw.-hr	$0.02013
Kw.-hr. per ton mined	4
Cost per ton mined	$0.08052

PURCHASED POWER (COST)

Tons mined	233,460
Purchased power (822,660 kw.-hr.)	$9,876.00
Repairs to substations	196.56
Supplies from store	19.92
Substation attendant	282.00
Fire insurance and workmen's compensation	125.28
Superintendence	2,160.00
Depreciation	844.08
Total	$13,503.84
Cost per kw.-hr	$0.01641
Kw.-hr. per ton mined	2.84
Cost per ton mined	$0.05660

tion through a period of about two years only. The results have been as anticipated.

Rotaries of the same rating as the motor-generator sets replaced have shown themselves to be of relatively greater capacity. Likewise they have shown equally as great reliability in service. I do not recommend the rotary under all circumstances; however, where the system from which the supply of power is obtained is a modern one, there is little or no exception.

(*To be concluded*)

Who's Who In Coal Mining

Charles E. Stuart

Efficiency is a product of spirit, mind and matter. While James B. Neale masters the spiritual forces of efficiency and production, he puts the two latter in the hands of his lieutenant, Charles E. Stuart, who, before his work is done, will give the operators many new ideas as to how they may avoid waste of effort and current, and who concurrently will deliver again preachments they have heard before, but which they have contrived to forget and let slide in the press of business.

Mine operators are of many types. Some having been bookkeepers are interested in the accounting department of the industry, others having been lawyers are absorbed in the legal matters connected with it, others having been salesmen regard coal as something

CHARLES E. STUART

to sell, others being practical men think of coal as something to be hustled. Charles Edward Stuart, member of the Production Committee, regards it as a material to be cut, hauled and handled mechanically and on the economic cutting, hauling and handling of it he has expended much constructive thought.

This view of the industry he is pressing on the operator. A mine owner without a mechanical bent will overlook the mechanical needs of his plant. When asked if he is losing power, he is likely to reply that what he does know is that a pump is needed in Fourth Right. He is apt to think he wants more plant when he needs merely to run what plant he has more efficiently. He evades his mechanical problems because he does not understand them and because they are not his hobby.

Mr. Stuart is on the committee to bring the mind of the operator who is not mechanically inclined gently but steadily back to those problems he has persistently and instinctively evaded. And Mr. Stuart, as our readers know from his articles on "Increasing Coal Mine Efficiency," now running in *Coal Age*, understands just where the operator without mechanical instincts is prone to slip up—or down.

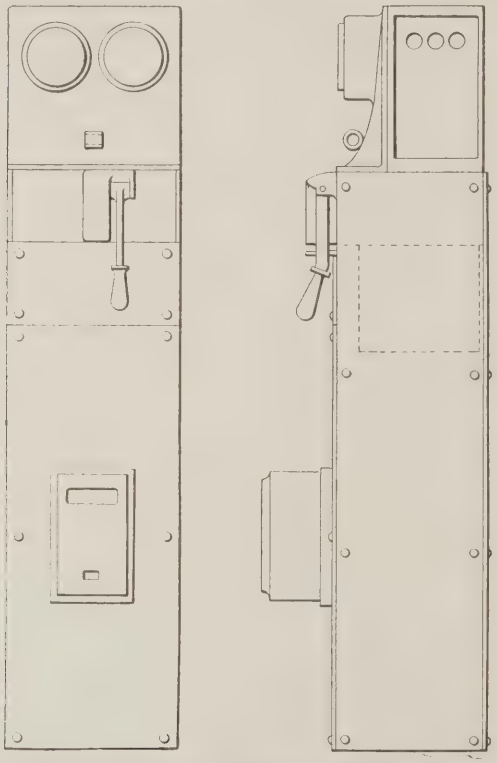
Charles E. Stuart was born at Alexandria, Va., on Aug. 29, 1881, the son of Charles Edward and Ruth Yeaton Stuart. His father and maternal grandfather were both legal lights, the first being a judge in his home state, and the second, Gabriel Max DuVal, being a justice of the Supreme Court.

With all his inherited leaning toward the law, which appears somewhat in his general appearance, Mr. Stuart struck out on a new path and took engineering as his profession. He attended the Virginia Military Institute, graduating in 1901. He then took a student course with the Westinghouse Electric and Manufacturing Co., receiving from them a degree as Electrical Engineer and an experience such as only work in an electrical plant can afford. He stayed with the Westinghouse concern till 1911, charge of one of the sales offices having been committed to him. It was his work for several years to introduce Westinghouse equipment into mines in an area extending from West Virginia to Alabama.

After this extensive experience, in which he became well acquainted with mine machinery, the coal seams and the men operating both, he became leading partner of Stuart, James & Cooke, consulting engineers, and took an active part in the installation of coal-mining, steel and other industrial plants.

When Mark W. Potter, chairman of the Carolina, Clinchfield & Ohio R. R., sought some one to study coal- and freight-handling facilities and the coal-handling arrangements of ocean-going vessels, it was Mr. Stuart who was chosen as his representative, his investigations taking him to Europe.

The war converted Mr. Stuart into a government administrator. He gave up his consulting work to take charge of the Power Section, and later became a member of the Production Committee. In the great period of reconstruction which doubtless will soon confront us, Mr. Stuart will take a leading place. The plans of the after-war period will make previous plans look amazingly crude. We are going to need consulting engineers who can visualize for capital a new order, who can catch a glimpse of a more finely adjusted industrial commonwealth where waste and inefficiency will be banned, A man relatively young and with vision, Mr. Stuart will be among those who will start us on this new path of progress.



Deeper Mining in Years To Come

Deeper mining becomes necessary as upper anthracite coal beds become exhausted. Water constantly has to be removed from the mines and the quantity reaches, is some collieries, as much as 25 tons of water for each ton of coal mined, increasing as lower beds are worked. As mining proceeds, year after year, the deeper and thinner seams must be relied upon, necessitating the removal of larger quantities of rock and refuse to get at the coal. Also mining at greater depths naturally requires more expensive ventilation, and as the mine grows in extent the underground transportation becomes more and more expensive.

NEW APPARATUS AND EQUIPMENT

Safety-First Induction-Motor Pedestals

In most industrial operations safety and efficiency are so related that an improvement in one usually effects an improvement in the other. More and better work is produced when working conditions are pleasant and healthful, and comparative freedom from liability to occupational or accident disability exists. In connection with the requirements of safety the panel shown in the accompanying illustration is of considerable interest. It is adapted particularly to the control of alternating-

FRONT AND SIDE VIEWS OF PEDESTALS

current feeder or motor circuits in capacities up to the rating of 300 amp. and 2500 volts.

The unit consists of a Type FK-20 oil circuit breaker mounted on a pedestal constructed of steel plates and angle iron, the former holding the latter in position and serving as mountings for the apparatus in the interior of the pedestal. The compartment immediately beneath the breaker and surrounded by the steel plates is used for mounting the potential and current transformers. The space above the switch serves as a housing for the disconnecting switch, and also provides a location for either voltmeter or ammeter or both when desirable. Other instruments such as watthour meters, etc., may be mounted on the sheet-steel front of the panel. The back of the pedestal is also a steel plate, removable to allow access to the interior.

The voltmeter and ammeter are mounted on a cast base above the breaker, and with the front edges of the instruments flush with the casting. Back of the instruments in the interior of the housing are spring contacts which make contact with the instrument studs, so that after removing the holding screws the instruments can be taken from their support without disconnecting the leads. When the instruments are replaced, the connections to them are made automatically. The instrument resistances are mounted behind the instruments.

The watthour meter is mounted on the lower front of the pedestal. The studs run through insulating bushings to the interior where they are connected to the leads from the current and potential transformers, which are mounted on strap-iron supports connecting the angle-iron uprights. The regular drilling of the supports permits mounting either one or two current and potential transformers.

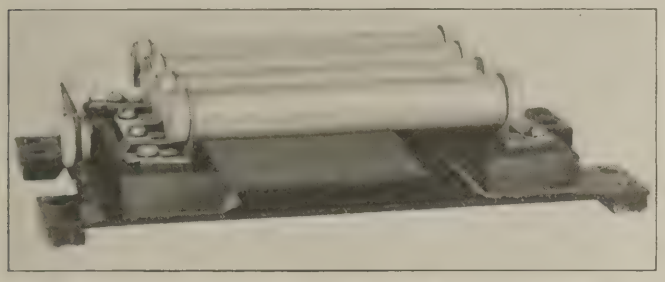
The FK-20 oil circuit breaker is operated in the usual manner by an iron handle from the front. Automatic protection is obtained by two series overload coils provided with dashpot time-limit trip. The oil circuit breaker can be operated only when the disconnecting switch is closed.

The disconnecting switch is operated from the front of the pedestal by a removable handle so interlocked with the oil circuit breaker that the disconnecting switch can be operated only when the breaker is open.

The breaker can thus be cut out of service at any time when open, and can be inspected or repaired without danger. The oil tank cannot be taken off the breaker nor can the cover over the disconnecting switch be removed unless this switch is open.

The disconnecting switch and the oil circuit breaker can both be locked open by removing the disconnecting switch handle. This handle can be removed or attached only when the disconnecting switch is open.

It is impossible to get at the live parts of the apparatus until portions of either the back or the front of the pedestal have been removed.



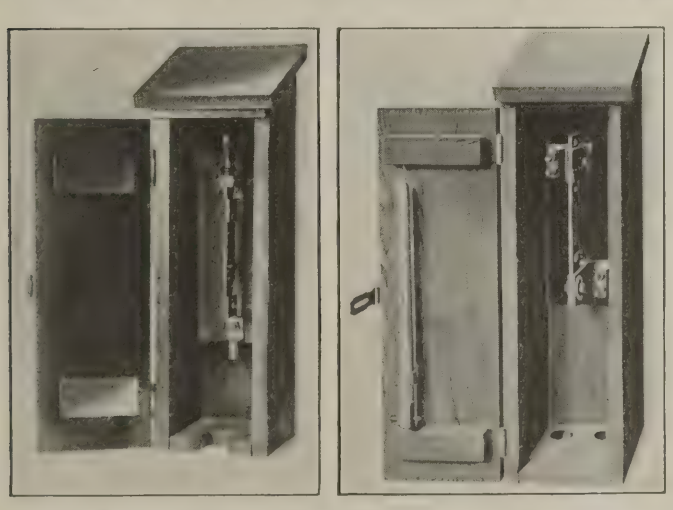
The panels occupy small space and are easy to install. Pedestal-type units are designed for single or group mounting and have a large bus compartment just above the disconnecting switch and inside the cast-iron housing. Connections run either to top or bottom of the pedestal, but as a rule the leads enter from the bottom as this is generally the more convenient arrangement. After being put in place the pedestals are secured by bolting to the floor.

Enameled Resistance Units for Current Regulation

Enameled resistance units for regulating current have been developed in various forms and sizes by the General Electric Co., of Schenectady, N. Y. Some of the applications to which these units have been put are railway and fire-alarm signals, fractional horsepower motors and locomotive headlights. They are also used extensively in series with relay, contactor and circuit-

breaker coils on panels and switchboards. They will be found particularly applicable in mines and similar places where a great amount of dampness and moisture is present. These units are unique in their ability to withstand unusually high temperatures as well as sudden changes in temperature from one extreme to the other.

The resistance wire or conductor is wound either upon a steel body coated with a special refractory



ENAMELED RESISTANCE UNITS

enamel or paint and high heat-resisting silicate compound developed to withstand sudden extreme temperature changes without cracking or weakening or in any way being injured. The steel body is preferred for extreme lengths where strength for a long span is required and is especially serviceable where the unit might be subjected to severe vibration or shock.

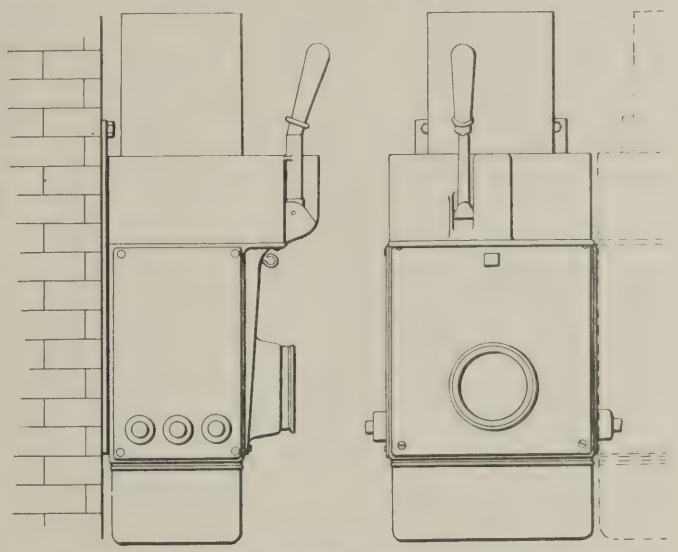
The refractory silicate body is used for most of the ordinary types of resistance. The compound employed is far superior to porcelain or any equivalent ceramic products which are easily cracked or weakened mechanically by repeated and extreme temperature fluctuations.

New Type of Line Switch

The accompanying illustration shows two types of line section switches of different capacities. The 750-volt switch is the one used for low voltages. It is provided with a wooden box so designed that when the switch is opened the handle drops into a slot in the

LINE SWITCHES AND THEIR INCLOSING BOXES

bottom of the box. This allows the door of the box to be closed and locked, thus making closure of the switch by unauthorized persons impossible. At the same time this exposes no live parts.



The other switch is a heavy-type service switch inclosed in a wooden box which can be locked. This switch is opened and closed by an insulated hook stick which is separate from the switch. Suitable attachments inside of the box hold the hook stick when not in use.

The smaller of these Westinghouse line switches are for potentials up to 750 volts and capacities of 200, 400 and 600 amp. The heavy switches are for voltages up to 1500 and capacities up to 1200 amperes.

Wall-Type Switching Unit

The wall-type switching unit here shown is manufactured by the General Electric Co. It is intended for the control of alternating-current circuits up to 300 amp. and 2500 volts. The unit consists of an industrial type oil circuit breaker with a space above which serves as a housing for a disconnecting switch, current and potential transformers and also provides a location for either voltmeter or ammeter, or both when desirable.

Following along the lines of safety, the disconnecting switch is interlocked, mechanically, with the oil circuit

FRONT AND SIDE VIEWS OF SWITCHING UNITS

breaker so that the switch cannot be opened when the breaker is closed, nor can the breaker be closed while the disconnecting switch is open. A key projecting through the front of the panel is used to operate the disconnecting switch. This key can be removed when the switch is open, and carried by the operator, who then is assured that no one will close the switch while he is working on either the line or apparatus on the circuit controlled by this unit. The interior of the switch compartment is inaccessible while the switch is closed, and the oil tank cannot be removed while the disconnecting switch or oil circuit breaker is alive.

These switching units are particularly adapted to the control of circuits feeding banks of transformers and motors, in places where it is desirable to mount the motor control appliances on walls or pillars. The units are self-contained and may be considered as "safety first" in every particular.

Wall-type units are designed for single or group mounting and have a large bus compartment just above the disconnecting switch and inside the cast-iron housing. Conduit connection with the unit can be made from above, below or from either side.

Paul Breathing Apparatus

The development of self-contained oxygen breathing apparatus has been coincident with the rapid growth of our industrial life. As mine entries have been extended and have penetrated to greater depths, the problem of rescue work has become one of vital interest. Strangely enough, however, it was not until 1907 that this important branch of the mining industry was taken cognizance of by the Government, in which year appropriations were granted by Congress to the technologic branch of the Geological Survey to purchase rescue apparatus and train men in its use.

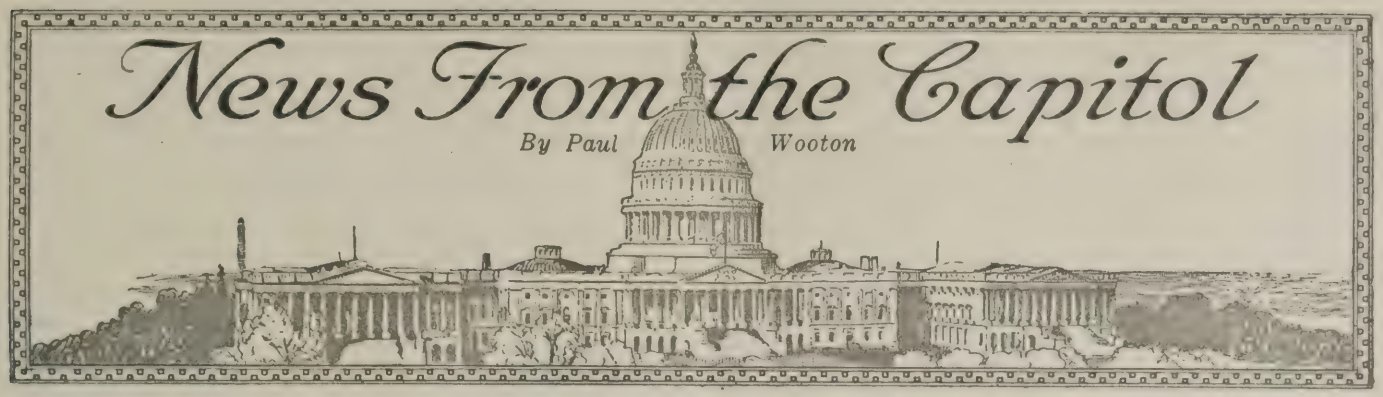
Prior to this date two large mining companies, one in the anthracite field and one a metal-mining company in the West, had installed rescue apparatus on trial, recognizing the need of such equipment provided, of course, that it possessed the proper elements of safety and efficiency. All forms of apparatus of this nature purchased by the mining industry in 1907 and thereafter until the outbreak of the great European war in 1914 were of foreign manufacture.

Nevertheless, the United States was not lacking in a proper and careful consideration of this important subject, and experts in this line were giving thought to the subject, having in view not only the perfection of the then existing forms of breathing apparatus, but the desirability of establishing the industry in this country on a firm footing, independent of the uncertainties of importing conditions.

When in 1907 Dr. Holmes, the "father" of the present United States Bureau of Mines (then the technologic branch of the Geological Survey), selected his lieutenants, who were later to become experts in their respective fields, he chose James W. Paul to take charge of the mine rescue and lighting division and Clarence Hall to take charge of the explosives division. Both of these men, who have since become well known in the mining industry, were by training and experience particularly qualified for the work which they undertook. Mr. Paul, a graduate in mining engineering from the University of West Virginia, who later amplified his training at Columbia University in New York City, was selected to organize the mining department of the State of West Virginia. This department grew under his direction for 12 years, after which he gave up the work to devote his energies to governmental investigation work and particularly to the use and development of oxygen breathing apparatus.

Mr. Paul's work since then is too well known to call for more than the briefest outline here. It is sufficient to say that he has attended and taken direct charge of the rescue work at probably more mine disasters and fires than any other person. He has made two trips to Europe in behalf of the United States Government to investigate resuscitation and study rescue methods abroad. And finally, he has given extended thought to the apparatus under actual working conditions with a view to improving the design. The findings of this research appear in Technical Paper No. 82 of the United States Bureau of Mines, in the preparation of which Mr. Paul had the benefit of the advice of one of the leading physiologists of the country—Dr. Yandell Henderson of the Yale Medical School.

During the period while Mr. Paul was not connected with the work of the Bureau of Mines, and while he was affiliated with Mr. Hall, who had previously left the bureau's service, he took out patents on the details of construction of an oxygen breathing apparatus which incorporated the results of the thought which he alone was able to give to this subject. This apparatus, which bears Mr. Paul's name, is now for the first time ready for the inspection and use of the mining industry. It is another indication of the dominance which the United States is rapidly acquiring in the field of applied science.



The Paul breathing apparatus, it is needless to say, has incorporated in its construction the requirements as set forth by Mr. Paul in Technical Paper No. 82. One of the highly essential and interesting features of this apparatus is the combination of the self-adjusting oxygen feed valve with the low pressure oxygen control valve in the intake of the circulatory system. Thus the operator during periods of violent exertion not only obtains from the apparatus all of the purified cool air that he can use, but a pressure well in excess of one centimeter of water column is maintained throughout the entire circulatory system.

A natural circulation is used in the Paul apparatus. The respired air passes direct from the mouth of the wearer to the regenerator, thence through the cooler and returns to the fresh-air bag, which is suspended on the chest of the wearer. Ample conduits throughout the system insure a minimum of resistance. The oxygen is fed directly into the bag as rapidly as required, and while there is always plenty to meet the most violent exertions of the wearer, it is at the same time conserved when he walks, works slowly or rests. The regenerator, or carbon-dioxide absorbing device, is of new construction and efficiently purifies the respired air to such an extent that during the full working period of a single charge, which varies from 3 to 12 hours depending upon the violence of the operator's exertion, not more than 1 per cent. of carbon dioxide ever passes into the inspired air conduits.

The Paul apparatus is well balanced. It fits the operator snugly and is easily and quickly adjusted. The conduits are carried at the left side of the wearer in a projected position, so that the right side and shoulders are entirely free for carrying forward the work in hand. Freedom of head movement is attained by amply long flexible tubes connecting the mouthpiece with the headgear and respiration chamber. The back part is hung low and is protected against damage by a metal cover. By means of a body strap the back part is held snugly against the body even while the operator is bending low.

The simplicity of construction of the apparatus with the few working parts provides an important element of safety. The pressure gage is carried in a pocket on the left shoulder and may be conveniently consulted. It is calibrated in atmospheres.

The mining industry of this country may justly feel gratified to know that American brains have accomplished so satisfactory a result as appears to have been attained in the new Paul breathing apparatus, and as it is to be manufactured exclusively in this country the uncertainties of importing conditions will not stand in the way of assuring the users of prompt delivery of the apparatus and parts.

Mines Producing Poor Coal Shut Down

The United States Fuel Administration during the week ended Oct. 28 issued orders to 13 coal mines prohibiting them from either shipping or mining any coal, making a total of 99 mines closed since the Administration inaugurated its clean-coal program. These orders were issued following reports from inspectors of the Administration which showed that either the coal from the mine was of such poor quality as to be useless, or the producers were not properly preparing the coal by cleaning it before shipment.

In the case of poor preparation by the operators, where the coal was found to be dirty and not usable, the companies were prohibited from shipping their output. The names of the operators affected by the orders are as follows: Kronnenwetter Coal Co., Benzinger Coal Co., M. Schieler & Son, Clemens Haberger, Erich Coal Co., Star Coal and Clay Co., Joseph A. Fritz, George Wolf, all of St. Marys, Penn.; McCullough Coal Co., Shanklin Coal Co., of Brockwayville, Penn.; the Liberty Coal Mining Co., of Madera, Penn.; J. H. Steele & Co., Kersey, Penn., and Walter Seidy, Black Lick, Penn.

Following the general policy of the Administration in not permitting any more than is possible of poor quality coal to be placed upon the market, the inspectors reported also 19 mines who were working veins with poor quality of coal in them, and these mines have been ordered to suspend operations from that portion of the mine. It has been the custom of the operators to mix this coal coming from poor quality veins with the coal from the veins of better quality, which does not conform to the policies of the Fuel Administration.

Offer of Coal to Holland Hurts Germany

Gratifying results of the international situation from the offer of the United States to supply Holland 100,000 tons of coal per month, if she requires it, already are in evidence according to information received by Harry A. Garfield, United States Fuel Administrator. Although all this coal may not actually be required, and possibly none of it will be called for, it has furnished an effective lever for the Dutch in their relations with the Germans.

Both Switzerland and Holland, it was stated, have been in vital need of coal, which at times the Entente Powers could not supply. When negotiations were afoot with Switzerland, the French, although already distressed for coal, united with the English in an offer of a far greater supply than that made at present by the United States to Holland. With this support the Swiss were immediately relieved from much German pressure and were able to negotiate with a free hand. They finally got most of their coal on a satisfactory basis from the Germans, and the French were actually called upon to furnish but little.

The plight of Holland was much worse, and the exports from Holland to Germany were considered of such moment that an offer of coal was made through the War Trade Board. Information reaching the Fuel Administration was that the Dutch, no longer afraid of being frozen this winter, are stiffening up in their negotiations, and our armies and the French in Northern France and Belgium are receiving supplies of fat which they need. The offer also has considerably affected German prestige, according to reports received, the Germans having insisted in their negotiations that America was utterly unable to furnish this coal.

Fuel Administration Engineer to Confer on Use of Illinois and Indiana Soft Coal

To further the educational campaign in Illinois, Indiana, Ohio, Michigan and Wisconsin, and to confer with the state administrators and local fuel officials on the use of Indiana and Illinois bituminous coal for domestic purposes, instead of anthracite and Pocahontas coal as heretofore, Thomas C. Mahady, domestic fuel engineer of the United States Fuel Administration, started Oct. 29 on a ten days' trip through those states. Meetings will be held at Chicago, Columbus, Milwaukee, Indianapolis and Detroit, and the best and most efficient means of using Indiana and Illinois soft coal in kitchen ranges and converting base-burner stoves to soft-coal heaters, with the most economic use of fuel, will be discussed.

Besides the change from anthracite to bituminous coal in the five states named, Mr. Mahady will confer with fuel officials on the problems of the distribution of local coal under the new zone system and the necessity for the extensive use of Indiana and Illinois bituminous. The conservation of water is another subject that will be discussed in the several gatherings of fuel officials.

The plan of the mayor of Highland Park, a suburb of Chicago, will be made the subject of an investigation by Mr. Mahady while at the latter place. When the order went out from the Fuel Administration at Washington that Indiana and Illinois soft coal must be used largely in place of anthracite, the mayor of Highland Park called in competent engineers and with their aid

worked out a plan to make every stove and heating apparatus quickly and cheaply adaptable for use of soft coal. Volunteer committees were then formed, printed instructions issued to every householder and personal instructions offered wherever it was necessary. Shortly thereafter the mayor sent out word that "Highland Park will use no anthracite or Pocahontas and everyone will be comfortable."

The success of the campaign, though purely local, attracted the attention of the Fuel Administration officials and Domestic Fuel Engineer Mahady was instructed to investigate it and make a report as to its practicability and possible use in other sections.

New Fuel Administrator for Virginia

R. H. Angell, of Roanoke, Va., has been appointed by Fuel Administrator Garfield to be Federal Fuel Administrator for Virginia, in the place of H. F. Byrd, who has entered the military service. Mr. Angell, who is a well-known banker and business man of Roanoke, was at the time of his appointment local fuel administrator at Roanoke.

No Eastern Coal for Western South America

The War Trade Board has been requested to stop issuing licenses for the export of eastern coal to the west coast of South America. The request is based on a desire to have the west coast of South America supplied with coal from the western states of the United States, leaving the high grade eastern coal for its important war uses.

Clubs May Use Certain Kinds of Coal

The United States Fuel Administration has issued an order authorizing each state fuel administrator to give country clubs the necessary permits to receive and burn, during the winter, bituminous or steam anthracite, whenever, in his opinion, there is a surplus of such fuel for this purpose. The authorization further states that under no condition should any country club be permitted to use domestic sizes of anthracite coal, either for cooking or heating purposes.

Coal Zone Permit Bureau Now Consolidated With Bureau of Statistics

The Coal Zone Permit Bureau of the Fuel Administration has been consolidated with the Bureau of Statistics. Wayne P. Ellis, the assistant director of the Bureau of Statistics, has been placed in charge of the permit activity, which will be known now as the Coal Zone Permit Section of the Bureau of Statistics. C. E. Lesher is the chief of the Bureau of Statistics. C. B. Nichols, who formerly had charge of the Coal Zone Permit Bureau, resigned to assist C. C. Marvel in by-product coke distribution.

Large Saving of Fuel in Merchant Marine

Due to the investigations of economies in combustion, which have been conducted for a number of years by Henry Kreisinger, of the Bureau of Mines, an important saving of fuel in the new merchant marine has been effected. Certain recommendations changing the design of the furnace of the boilers which are destined to run the emergency fleet make it possible for six tons of coal to do the work which formerly required seven. This accomplishment is heralded as the outcome of purely investigatory work which, when applied in practice, has shown immediate results.

New Prices for Alabama Coal

New prices have been authorized for coal mined by the West Helena Coal Co. in Alabama, as follows: run-of-mine, $3; prepared sizes, $3.30; slack or screenings, $2.65. Prices for coal mined by the Warrior Pratt Coal Co. have been fixed as follows: run-of-mine, $2.25; prepared sizes, $2.50; slack or screenings, $2. In each case, forty-five cents may be added if the terms of the Washington wage agreement are met.

Surplus Coal at the Mines

A surplus of coal at practically all mines west of Pittsburgh has been reported to the National Coal Association. While exact figures are not available, it is known that the surplus tonnage is very large. The condition is attributable largely to the possibility of an early peace. As long as an early peace is a possibility it is expected that certain classes of manufacturers will not keep their storage at the maximum limit. If, on the other hand, Germany should decline to accept the terms of the allied armistice, it is expected that the surplus will fade out very promptly.

Another influence which has contributed to the surplus is the exceptionally favorable weather which has prevailed throughout the country for the past month and more. November of last year was ushered in with unusually cold, bad weather which interfered very greatly with transportation.

No Soft Coal Shortage in New England

Continuance of good weather has made possible maximum deliveries of coal to New England where the storage is now sufficiently large to preclude any probability of a shortage in that section this winter. Some difficulty is being experienced with anthracite, but that is said to be due more to inequality of distribution than to shortage. There is still a very marked shortage of navy coal. Owing to the very strict inspection, upon which the Navy insists, a portion of the coal which was included in the estimates for the Navy requirements are not passing the test.

From incomplete statistics showing the coal saving made possible by the skip-stop method of operating street cars, the Fuel Administration estimates that a 10 per cent. saving of fuel is resulting.

Due to the successful results which have been obtained by the methods employed by James B. Neale in stimulating coal production, a similar plan is to be carried out with regard to coke. The work is to be under the direct supervision of W. S. Blauvelt.

The Fuel Administration announces that manufacturers of incandescent electric light bulbs, by agreeing to limit the production of lights having carbon filaments and substituting them with the more efficient metallic filament types, have made possible a saving of one million tons of coal annually.

THE LABOR SITUATION

General Labor Review

At last, Oct. 31, the final action by Fuel Administrator Garfield has put the new schedule for the anthracite region into operation. Just as legislation is passed by one House in Congress, approved by another House, signed by the President and interpreted by the local Federal Court and the Supreme Court, so now wage schedules are made by a commission of operators, miners and fuel administrators, approved by the conference of National Labor-Adjusting Agencies, signed by Dr. H. A. Garfield, the Federal Fuel Administrator, and interpreted by the courts of mine workers and foremen, of labor leaders and managers, by the Anthracite Conciliation Board or by the umpire of that board. The process is complicated in a degree, but that is necessary and therefore excusable.

The Fuel Administration in its Oct. 31 bulletin says as follows: Wages in various mines are not identical to the cent, and an absolute interpretation of the scale in dollars and cents as to every mine worker is therefore impossible. A memorandum was submitted to the Conference of National Labor Adjusting Agencies, as being fairly typical of the general situation. In some instances the wage increase received will be materially less, and in some instances materially more, than the tabulation shown below:

WAGES OF EMPLOYEES WORKING OUTSIDE THE MINE

Occupation	Base, Cents per Hour		Adjustment, Cents per Hour	Rate, Cents per Hour	
Blacksmith	.32	.35	.25	.57	.60
Carpenter	.32	.35	.25	.57	.60
Shaft engineers	.36	.40	.25	.61	.65
Firemen	.23	.28	.25	.48	.53
Machinery repairmen	.30	.32	.25	.55	.57
Laborers	.195	.235	.225	.42	.46

WAGES OF EMPLOYEES WORKING INSIDE THE MINE

	Base	Adjustment	Rate
Contract miners*	$5.63 per day	$1.00 per day	$6.63 per day
Contract laborers	26c. @ 40c., per hour	30 per cent. plus $1	$3.70 @ $5.16 per day
Consideration miners	40c. @ 45c., per hour	25 per cent., plus $1	$5 @ $5.50 per day
Company mines	32c. @ 35c. per hour	25c. per hour	57c. @ 60c. per hour
Inside laborers	26c. @ 29c. per hour	25c. per hour	51c. @ 54c. per hour

* Average per start, Aug. 18.

It may be added that the base mentioned is not the scale of Nov. 17, 1917, but the scale of May 5, 1916.

The increase, even before it was finally granted, awakened what might fairly be called the cupidity of the bituminous miners. The basis for the increase was the larger wages of the bituminous mine workers. It was acknowledged that there was a differential between the two wage scales which, under present conditions at least, was inexplicable. So the anthracite mine workers' wages were advanced. Now the bituminous miners assert that they should receive an equal advance. They have presented their demand to the labor-adjusting boards and to the Fuel Administrator. It has not been met with disdain; it has been met with sorrow. Patriotic men find it hard to conceive how any men proclaiming themselves patriots can, without having any basis for complaint, present at this time a demand for more wages.

The bituminous mine workers on Nov. 1 presented their protest to President Wilson saying that Dr. Garfield's refusal was arbitrary, autocratic and unfair. The telegram states that they (the bituminous mine workers) deeply resent the treatment accorded the spokesmen of the miners of the United States by the Federal Fuel Administrator Garfield.

In central Pennsylvania the mine workers have been greatly worked up over the fact that their tonnage has fallen because of the epidemic. Approximately 10,000 patriotic mine workers went into the mines on Sunday, Oct. 27 and loaded about 50,000 tons. The influenza has had a bad effect throughout the United States. In the week ending Oct. 26 only 11,215,000 tons of bituminous coal were mined, which is a decrease of 309,000 tons from the week before. The production of anthracite dropped to 1,714,000 tons, a fall of 17 per cent. from the output in the same week in the year before. Influenza is reducing production in Iowa, Missouri, eastern Arkansas, Oklahoma and Texas.

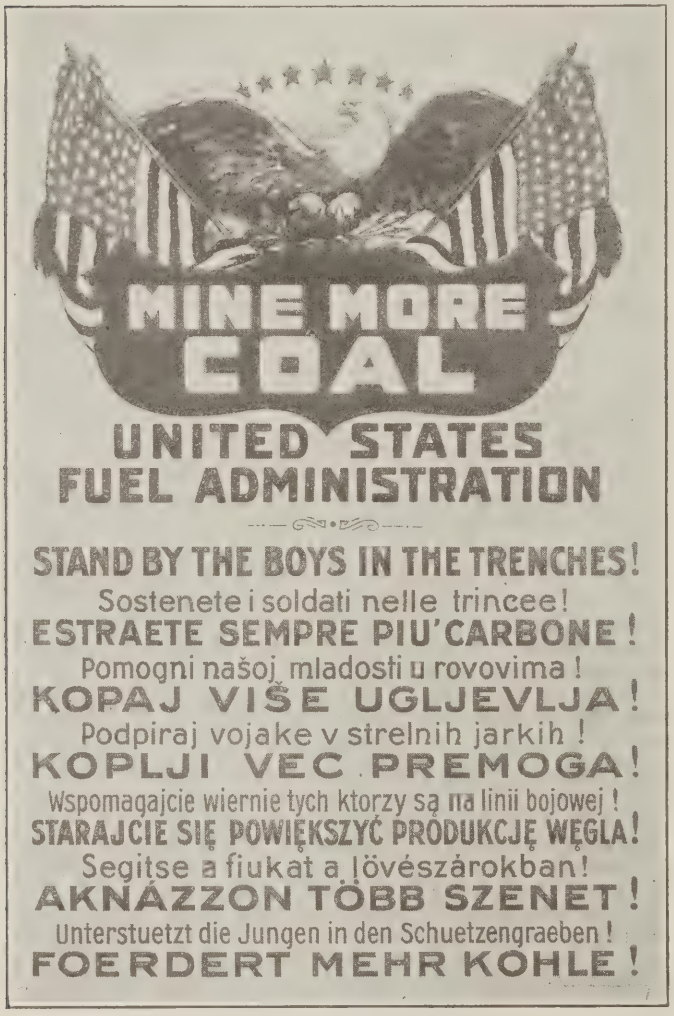
To return to the affairs of central Pennsylvania, an effort to increase production by promising a big banquet to the Westmoreland County mine which makes the greatest average increase in its coal production during November is worthy of record. The competition will be limited to those mines which produce 10,000 or more tons per month.

It is probable that the mine winning the dinner will also land the service flag for one month. This flag is to be awarded each month to the mine making the greatest actual increase in its output. A mine which wins and holds the flag during a series of months will be awarded permanent possession of the honor banner at the close of the coal-production campaign.

Chickasaw Averages $189.02 Per Worker

At the Allegheny River Mining Co.'s mine at Chickasaw, in Armstrong County, there are 205 names on the payroll. Every person on that roll has a Fourth Liberty Bond and the total subscription is $38,500 or $189.02 per person and about $1000 for every boy in France, for the town has furnished 39 valiant sons to the service. This is a splendid record of patriotic effort. As the quota through the United States, exclusive of New York, is $46.66 per person, earner and nonearner alike, it is clear that the record of the earners of the Chickasaw mines is high enough to place the whole village in a position of having done its full share.

From Williamson, W. Va., comes a remarkable report of performance regarding H. L. Witt, an employee of the Chattaroy Coal Co. Writing to us, O. O. Milby, the manager, says that he is very proud of Witt's record and feels it is worthy of publication. It certainly is. Witt, who is 35 years old, loaded, since Jan. 1, up to and including Oct. 23, 3164 two-ton cars or approximately 6828 tons of coal. He has purchased $4500 worth of Liberty Bonds, $100 in War Savings Stamps and he has contributed "very liberally to the Red Cross and other charities; the exact sum," says Mr. Milby, "we do not know." Mr. Witt is a ready and willing worker, very seldom missing a day when he is able to work.



The miners in the Illinois fields adjacent to St. Louis have probably lost no time because of the influenza, for if there had been no epidemic the mines might have been shut down for lack of demand. The operators believe that the disease served to limit the output when a limit was advantageous.

In the Springfield district, the output of which goes mainly to the north and northwest, production of the 18 mines in the vicinity of Springfield and of the greater number of mines in the district is getting back to normal. A week ago three of the Springfield mines were closed, principally on account of the influenza. These were the Chicago-Springfield, the Woodside and the Jones & Adams. Now all of these are working. There is still some shortage of men, but probably that shortage will not exceed 300 men, and the resulting curtailment of production will not exceed 1800 tons a day.

David Wilson, member of the Miners' Executive Board in the Belleville District, says that the Baltimore & Ohio RR. and the Louisville & Nashville RR. have not been able to supply enough cars for the mines in their territory. Wilson and other leaders among the miners also complain

that repairs and machinery defects cause frequent shutdowns. The operators, on the other hand, say that the men are irregular in their work, and exhibit their payrolls to prove it. They say that the greatest loss in production is due to the failure of the railroads to furnish cars and that the next greatest loss is due to the laying off of the men to "blow in" their big earnings. At some of the mines the men, in order to escape the charge of laying off, ask for their time and quit and when they have spent their money they return to work. Because of the shortage of labor the operators have to put up with the practice.

The miners' organization of Belleville, Ill., has subscribed for $150,000 of Liberty Bonds. This is a part of the $500,000 which is to be subscribed by the state organization.

Many mine washhouses have been closed in order to prevent a spread of influenza. Special efforts are being made by Director Drake of the State Department of Health to prevent the occurrence of such conditions in the Illinois mines as have existed recently in those of Kentucky. Special representatives of the State and United States health organizations have been sent into all of the mining centers. A strict quarantine has been established at Roseclair. Reports are that the disease is subsiding in the northern part of the state. There has been some increase in the disease in the central and southern portions.

In Vancouver Island an excellent principle for some time in force in eastern British Columbia does not appear to have been operative. That principle was to increase wages with changes in the cost of living. As the prices of commodities rose the mine workers of Vancouver Island found themselves progressively impoverished, and they demanded an increase of $1 a day. With an inadequate inquiry, but with a desire to satisfy an inequity recognized as existing in the old contract, J. D. Bulger, Dominion fair-wage officer, and Nichol Thompson, British Columbia adviser to the Fuel Controller of the Dominion of Canada, offered an increase of 75c. per ton, which was accepted.

The final arrangements were made Oct. 24. The mine workers wanted an immediate readjustment, but the operators opposed this, saying that the increase in wages should go into force concurrently with a rise in price and that could not be arranged with the Fuel Controller till Nov. 1. The latter, therefore, was the date adopted.

Vancouver is to get a sliding scale of wages to accord with costs of living. Next January the first adjustment will be arranged but not made. The increase in wage will not go into effect till February. Meanwhile the public will know what to expect and will make arrangements accordingly. Every three months a commission consisting of the fair-wage officer and representatives of the operators and mine workers will appraise the cost of living, render a decision as to the increased wage which will countervail it and then the new scale will come into force one month thereafter.

After the War

By Josiah Keeley

General Manager, Cabin Creek Consolidated Coal Co.
Kayford, W. Va.

"Making the world safe for democracy" is now one of the world's best-known phrases. "Making democracy a safe thing for the world" is also in the minds of many, but it is an after-the-war consideration. However, we can not too soon begin to draft the policies of the reconstruction that may follow the war.

Two years ago, at least one large coal company expressed itself rather frankly as to the impropriety of a coal journal devoting a whole page, or even more, to "The Labor Situation." Many companies seemed to feel that they could avoid having any labor situation by not admitting publicly that any such thing existed. But during these same two years they have had little else to think about, and some of them have contributed materially to the establishment of the present labor situation.

The more violent labor agitators are fond of representing that labor is being "emancipated," hoping to force on the minds of the public an analogy between the condition of the negro and the status of the workingman. If we are to accept this viewpoint of the labor situation as true even in part, then, for the good of the country, we should seek to avoid some of the mistakes that were made in the freeing of the slaves.

If the Man of Galilee should at the present time preach to us the doctrine, "Render therefore unto Caesar the things that be Caesar's," the public might promptly answer that, if it was consulted, there was not going to be any Caesar. But this much-quoted Biblical doctrine has been held to teach not autocracy specifically, but the acknowledgment of constituted authority, democratic not less than autocratic; and, if this is the right interpretation, what we shall have to determine now or after the war is, what are the things that belong to Caesar.

Of course, there would be no special propriety in taking up space in a coal journal on so general a proposition, if it were not for the fact that the labor situation is a topic of growing importance in mining villages everywhere. Most other industries are located in the cities where they are policed more or less by the civil authorities, but the coal camps are isolated centers with little civil authority in evidence short of the county seats. They are consequently fertile fields for disorder Moreover, small places are so unified in their purposes and sentiments that a non-partisan administration of justice is not attainable; and, even if it were, it would be inadequate to cope with the pressure that a large camp of miners might be able to bring to bear on it.

While the growing strength of organized labor is not necessarily a menace, there are enough uninformed individuals who take the idea of an actual emancipation so literally that there is a question whether the more moderate workmen will be able to set any definite limit to what is a necessary authority, and as to what constitutes a reasonable demand from labor.

Those who express such a fear may be held to overlook the value of the discipline which an organization of indus-

trial workers can exercise when led by men properly vested with authority. But such leaders do not have matters all their own way. However wise they may be, disobedience is prevalent, and violations of contracts go unpunished. However moderate they may be makes little difference, when they are but the mouthpieces of "emancipated" laborers. Such considerations give us pause whenever we begin to show too great a confidence in the powers of control and the ripeness of judgment of the men in charge of the union.

After the war, these leaders will no longer be able to invoke war necessities as they can at the present critical time when our sons' lives are hostages for our good behavior. Every week we find that outbreaks against union orders are quelled only with the greatest difficulty. Whenever some real or fancied advantage is at stake, the loyalty of the mine workers to the nation as a whole is apt to give place to a loyalty to their immediate fellows or to some other "thing which nearer lies."

Some Contracts That We Also Have Scrapped

We are spilling the best blood of America to repudiate the nation which considers an agreement but a scrap of paper. Yet at the same time the unions are, by threatening strikes, tearing up wage contracts, which they themselves, and not their forbears, just as solemnly signed, only a few months ago. In the newly conceived democracy of labor, one hundred per cent. of loyalty to contract is the only thing to differentiate America from Russia. It matters not how loyal the organizations are if they lack responsibility. The English Dissenters, the French Jacobins, the Roman Plebeans, and the Russian Bolsheviki all had some good leaders, but not all of them were able to subdue the spirit which their magic had raised.

Why should we not devote space to our labor situation? It is a dangerous case when such a fear weighs on the public that it shrinks from discussing it. We all know that labor can out-vote and out-fight capital if ever it makes common cause against it and forgets for a while the services that an oppressed, but rightly regulated, capital can perform for the working man.

The present war is far from being a "rich man's war." It brings nothing to rich men but the opportunity for sacrifice and service. It is even more costly to the rich than to the working man, and it offers opportunities to labor which labor has not been slow to recognize. And certain kinds of labor feel that the advantages the war affords have not been cashed in as yet. The ultimate reckoning it feels will be completed only—"after the war."

"After the War" Will the Sky Be the Limit?

"Mother" Jones is touring the coal fields urging the production of coal and the buying of Liberty Bonds, but after every appeal she points to the goal to be reached "after the war." Germany's toast, "To the day," and Madam Defarge's laconic salutation to her Jacobin hosts, were never more significant than this labor slogan of "After the War." Not necessarily a challenge, not necessarily sinister, but embodying potentialities for a national calamity if not guided by sympathetic hands.

The extraordinary wartime wages, now enjoyed, appear to many labor enthusiasts as a direct victory secured by labor as a result of its presenting to capital an unbroken front. Not knowing exactly the things that are Caesar's, and having no way of telling just what the limit might be as to shortness of hours and size of wages, the national tendency is to make the sky the limit and let Caesar look out for himself. Since the Government, a hazy sort of something at Washington, has put forth a restraining but kindly hand and said, "Not now," why, of course, *after the war* must be the time.

With the publicity that has been given to production cost, and with a government selling price, there will not be much excuse if labor does not know what the operator is getting out of the coal business the next time an agreement for a wage scale is sought. The public will be informed, too, so the only question to be settled in the after-the-war working agreement is how much of the joint product of labor and capital rightfully belongs to each. The public has been assured repeatedly that after the war labor will get its "full share." Until that time comes and the demands are made we shall not know whether labor realizes that there is a just limit to its demands or harbors an insane vision of confiscation.

It seems that from the beginning there has been a groping for a better condition for labor. The early Christians looked for an earthly kingdom in which fishermen should rule over the Roman Caesar, and, in anticipation, questioned the payment of their taxes. From the beginning of the coal industry, the discipline of the coal companies, in many cases, has been the only check on the life of the coal camps, the company being so closely identified with the civil authorities that little distinction was made.

When the civil authorities went into a camp for an offender against the civil law, some company official was called on for assistance; and, if any witnesses were necessary, the company furnished them. Under such conditions, disloyalty to the employer was practically disloyalty to Caesar. While in some instances this identity of company and state might have been sought for, in most cases it came about naturally from the very nature of things, those possessing anything to lose controlling the custodians of the law in the isolated camps.

It has been impossible to fight Kaiserism abroad without some introspection at home, and it is perhaps natural that the minds of labor turn to their old enemy, capital, and hang on it all the iniquities of Kaiserism.

Operator Was Formerly Leader of His Men

Less than a score of years ago the political strength of most of the big labor-employing industries consisted in their ability to deliver votes. They did not necessarily use any sinister influence, because the men accepted the leadership of their employers. With the coming of labor organizations, votes are bid for in another way, and the only political strength left to capital is to use its money, when it has any, in issuing circulars and arranging political meetings.

After the war, the coal companies may face their employees somewhat in the role of a discredited Kaiser. They will have imputed to them their old-time faults, for which they are not entirely responsible, and they will be credited with many new sins, which will be grouped under the generally detested head of Kaiserism. On the other hand, labor will stand "emancipated" with a country's blessing on it for its loyalty in the great war. Its treasury will be full of money; its membership will be largely increased, and its spirit will be rendered as militant as the spirits of the sons of labor who will then have returned from destroying Kaiserism abroad.

United under the leadership of men, who, for the period of the war, have helped to advise our government; armed with votes and with governmental sanction; and, finally, having a definite time set for getting its share—namely, after the war—what may not eventuate if some attempt is not made to meet the difficulty by the education of everyone to the true course of action.

Settle Neither by Force Nor by Cunning

In all probability this vision is more or less fanciful, but that it may assume such an attitude should never be overlooked. Probably many of the wiser heads among the mine workers would do their best to prevent any such situation, but it is unquestionably in the minds of enough of the radicals to give it at least a beginning.

An abundance of labor after the war may have a steadying effect, but the attitude of both the operator and the labor leaders upon approaching the conference will largely determine the ultimate outcome.

If collective bargaining is to be the coming method of determining wages, then it ought not to be a question of one side wringing concessions out of the other, and going back to constitutents to say, "We got the best we could." As long as a wage scale is to be determined by the amount of pressure which one side can bring on the other, so long will there be an incentive to organize the sides in such a way as will make democracy unsafe for the world.

EDITORIALS

Let Us Be Liberal Hosts to Our Men

THE war is not over. What is more, we do not know when it will end. But if it were over, entirely over tomorrow, the money of America would have to be poured out nevertheless for war-camp activity. For with war there is idealism and there are duties. There will be no letting down in the presence of national enemies. Never for a moment will we forget that we are Americans, to serve, to suffer and to sacrifice, till the hostile flags arrayed against us are lowered and until that to which we have set our hand is fully accomplished.

When peace returns and the work of the soldier comes to an end, we will have a host of men abroad in foreign cities with little or nothing to give them amusement and comforts. Then will we need the organization and recreational equipment that will take the place of the war as a stimulus to our men.

The best and wealthiest of us at times need a little welfare work. The rich man looks for a club where good fellows meet for healthful social intercourse, or he hunts him a friend in the city he visits. Our boys in France, Italy, Great Britain, Russia and Siberia have no clubs or friends to take care of them in their leisure moments except those supplied by these war activities' funds, which from Nov. 11 to Nov. 18 are going to appeal to us for $170,500,000.

They are going to get every dollar of that sum, that they may make good hosts to our men. Let it never be said that we, the people of America, were not generous entertainers to our nation's defenders. If we fail of this duty not only will we find the morale of the service destroyed, but we shall weaken the bond that makes the nation one. It is because the nation has been such a generous host to its boys that they have been so willing to pour out their lives and their efforts so unsparingly in its service.

We need Americanism not only for the foreigner, but for the native born. We need that it shall be deep in the heart of us all, and in no way can the unity and the spirit of the nation be more truly assured than by our hearty acceptation of the opportunity of acting as the gracious hosts of our valiant defenders.

General Pershing has said that every hut adds ten men to a quota of one hundred for, largely by reason of the war fund activities, no war has ever been fought with as clean and well conducted an army as America has sent to the Old World. But that which has made these men fight like lions and conduct themselves so admirably will serve to make them in peace and on their return the great nationalizing force of the nation. These men, on coming back to America will, by their ideals and their youthful enthusiasms, vitalize all our institutions. Let them come back filled with the conviction that we were worthy of their sacrifices and that we did not forget our duty to them even when the war appeared to be approaching, or had reached, an end. Here's to our guests, the Boys of the U. S. A.! May they, who have given so much for us, never be able to say that we begrudged to them a little entertainment and a few of the comforts of home.

After the War

EVERY one will be interested in the thoughtful remarks of Mr. Keeley appearing in the "Labor Situation" under the head "After the War." Mr. Keeley is a man of such broad mind that we regret that he has taken to "sounding a warning," a thing so contrary to our national characteristics. Mr. Keeley can see no harm and much gain in facing the facts. That is a part of the right attitude, but not the whole. There should be another ingredient in the dish—no less an ingredient than a flavoring of American optimism, the condiment that makes the bitterest of viands palatable and even nutritious.

After the war there is going to be no radical reconstruction, nor are we going to have years of uncertainty such as marked the period after the Civil War. The soldiers are not coming home to fight but to build. The workingmen and the nation's planners are going to have a broader vision. It is true a number are crying "After the War," but with most of us it means not strife, but reconciliation; not disorder, but the reknitting of scattered families.

The biggest of all reconstruction is a reconstructed spirit, a sense of unity and friendliness, a kindly knowledge of each other as of one flesh and blood, little better and little worse than one another.

The difference between bad labor men and good labor men is largely between men who know the labor movement but little and those who know it well. The rabid man once brought into touch with the employer soon realizes that the man he painted so black is merely another man much like himself, and he loses a spirit of rebellion and becomes almost a coöperator. That is why these veterans of unionism are usually disliked by the rank and file after a few years of service. They have learned to know and respect capital and have begun to realize that with all its faults capital is at least as clean as labor.

Labor has not in general learned that lesson, and it punishes those who have. In consequence the workingmen continually bring new men forward, men unlearned in the labor movement. As fast as they are honored with office they begin to learn the truth, and they cannot then be even goaded to follow policies they once led others in advocating.

Even Mother Jones is becoming less militant as the opposition to her action lessens. She is growing more tolerant as the result of the tolerance that is shown her. Doubtless she never was without a certain degree of those good qualities we associate with "woman." The

violent are not without tenderer sentiments. They could not appeal to the hearts of others unless their own hearts had something of the human quality. All of us have heard from the lips of labor agitators at some time the acknowledgment of their two-fold disillusionment—how they have lost faith in the vision of a workingman commonwealth in which every man is upright and loyal and how they have been disabused of their old belief that greed and a lack of human qualities were the distinguishing traits of the employer.

But if the labor leaders can be brought to a better understanding, why rest content with converting *them?* Why not stop raising this crop of uninstructed leaders? Why not educate all the men into the true labor situation? Let the miner learn the whole truth and see just what the operator is facing, how profits are usually only made by hours of watching and every kind of mincing economy. Let him understand the operator's difficulties, and above all let him know the operator, as much as may be, as a personal friend. It can be done, for it has been done already.

Above all, let us remember that the miner is not a problem—he is a person. A cheerful, undoubting optimism will win the miner to a reasonable state of mind. If he is given an opportunity to earn such wages as seem quite common in the bituminous region, surely he will remain content. The wage earners who have received little or no increase in wage since the war began, and there are not a few of them, call on the miner not to demand a further increase in the price of coal. Those whose earnings have fallen steadily in purchasing power are disposed to protest bitterly at a spirit of profiteering which demands of the public ever more and more.

Some one must buy what the miners have for sale, and if the price is boosted without limit other workers will be unable to secure for themselves a livelihood. The wage of the miner is paid by the sweat of workingmen, the larger the wage the more heavy the sweat. Our prayer to the miner is that in seeking the best for himself and his family he remember to be fair to those who are not engaged in mining work, or in such work as has been endowed like mining by the war.

In all of this no reference is made to the anthracite settlement. The anthracite daymen do not get an unreasonable wage and the anthracite contract miner has not received any undue advance. But the bituminous mine workers are receiving magnificent wages and should be content with them. The workingmen of America are little disposed to pay them more.

Relation of the Operator to Health

INQUIRY as to the attitude of other journals to health brought the reply: "We do not mention such things in our journal. We leave that to boards of health. It is a doctor's business to take care of the ailments of the people and not the business of the employer; so we do not think it within our scope to consider the etiology of disease."

It is not necessary to argue this question. It is so clearly refuted by the present conditions. The doctors who compose our health boards are rushed to death. Their work is with the dying. They have no time for preventive methods except an occasional word said when in the home of a grievously sick person. Somebody else must take up the burden of prevention; others must proclaim the gospel of cleanliness and isolation. Otherwise production will fall.

Influenza has nothing to do with mining—except to stop it. The disease is spread in the social life of the people rather than in their industrial life. It is not in the mine or the street, but in the house, that the evil is done. Judging from the experience in New York where free assembly has been little interfered with, there is no advantage in keeping people from congregating. The only action of the Board of Health of the City of New York has been to keep children out of the theaters and to try to avoid crowding in transportation. As for the last, the effort has been an entire failure; the crowding is worse than ever, but nevertheless the influenza germs do not seem to take advantage of that fact. The epidemic in New York City, despite the crowding of that metropolis, is less severe than in most sections of the country.

The poster this week calls attention somewhat unpleasantly to the evils and dangers of the home. Isolation of each individual is the lesson which the poster tells. It cannot tell it as well as it could be told in public meeting, were such meetings allowed. It should be announced again and again, that individuals should keep such germs as they have acquired and not pass them on to one another. As far as may be, every person should be isolated from his neighbor.

In our editorials emphasis has been laid on the carriage of disease using such vehicles as the towel, the apron, the knife and fork and the pencil, but there is no purpose in denying that influenza can also be readily communicated from person to person through the breath. With what celerity and at how great a distance can a man who has been chewing garlic or peanuts make himself felt! If odors can thus be projected into the atmosphere, what possibilities must exist as to the projection of germs. Your garlic-eating foreigner is an ever-present exemplar of infectious disease. If only the influenza germ were of a character that it would assail our olfactory nerves like garlic, we would gain some knowledge of its universal presence and make adequate provision against it.

Reason for House Scarcity

WHEN BOYS leave for the front or for the munition works they do not take with them their fathers, mothers, brothers and sisters. These relatives still remain, and the reduced family takes the same housing equipment as of old. A bedroom, perhaps, is idle, but no one comes to occupy it. However, as the result, the mine is now short a man, and another man is hired. He is quite apt to be a man of family, and unlike the boy who goes to camp, he brings his family with him. Thus merely by labor turnover the efficiency of housing is decreased. The blocks of houses cannot care for as many as they did.

Again, the boarding-houses have largely been depleted of their men. Some ten or twelve unmarried employees may be found living in a single building. When these men are replaced in the mine, it is likely to be by ten or twelve or more older men, who, being older, achieve less and, being married occupy more houses. This is another of the causes of house shortage.

Influenza is not the only disease which is spread by the nose and mouth. There are several others, and, if they are to be avoided, we must beware of other lips and of anything that other lips have touched or rendered foul.

DISCUSSION BY READERS

Hindrances to Coal Production

Letter No. 5—While I do not believe that, as a rule, the average coal miner is a drunk or a sot, yet observation shows that many tons of coal are being lost daily by reason of the fact that many miners and men working in and around the mines lose several days a month, in order to satisfy their desire or thirst for drink. It goes without saying that the majority of these men would be in their places regularly if there were no saloons or places where they could buy liquor.

Living here, on the border of a wet state, one cannot fail to be impressed with the fact that the sale of liquor and the booze habit among miners are most important factors in the hindrance of the production of coal. Train after train brings men from the various coal fields to the nearest wet towns, and it is only natural to assume that the majority of these men are workers in and around the coal mines.

Leaving the mine, they go in quest of drink for which they squander their money. But that is not the worst, and before returning home they are leached by men and women who make their living by many nefarious vocations and are always found in the vicinity of saloons.

IDLE TALES OF RECORD PRODUCTIONS

It is no uncommon thing, today, to listen to the tale of wonderful production records, which are seldom based on fact, however, but are the dreams of a brain robbed of its power of lucid reasoning while under the influence of "John Barleycorn." If all of the coal represented by these claims was loaded into mine cars and dumped into railroad cars for shipment there would be no coal shortage in this country.

While I am not, personally, a prohibitionist, I have seen too often the dread effects of the booze habit, and have yet to observe anything but trouble, sorrow and disease in various degrees, from the slight headache of the "morning after," to the murder committed by a whiskey-crazed man and which invariably brings serious consequences to his entire family and deepest sorrow to those bereaved, to say nothing of the expense imposed on the state and municipality where the deed occurred.

Practically, the only excuse for the manufacture and sale of intoxicating drink is the revenue derived from the business, which I am glad to say is on the decline. Being a nation founded on the government by the people and for the people, it seems to me that a failure to stamp out this evil will be a detriment to the many. The few people who are engaged in the business of making and selling liquor reap their profits at the expense of homes and sorrowing women and helpless children, who are deprived of their rightful support. The country, moreover, is deprived of tons of coal, which is badly needed, at the present time, in support of the army of sturdy fighters we have sent overseas.

Let us strive, then, to make our mines greater producers, by installing better machinery where needed and encouraging our men to turn a cold shoulder to old "John Barleycorn" and, if possible, run him out of the country.

Huntington, W. Va.

Americanizing the Foreigner

Letter No. 6—Referring to the letter of "Experience," which appeared in *Coal Age*, Aug. 8, p. 286, regarding the assumed hopelessness of educating the foreigner and causing him to adopt American ideals and customs, permit me to challenge the remarks contained in that letter and others that have followed.

For the past four years I have devoted my entire time to community work in coal camps, and have had many dealings with people who have come from other countries. These people are naturally suspicious of strangers, and in many cases their suspicions are well founded, but when they are convinced that you come to them as a friend, their response is most gratifying.

FIG. 1. A MODEL SLAVISH MINER'S HOME

Once you win their confidence, they place in you the same implicit trust that we find in children. Many times, one is almost overwhelmed by the magnitude of their trust. More than once, when some one has been sick and the doctor has changed the medicine a member of the family has come to me wanting me to taste and smell the new medicine before they gave it.

One instance that touched me deeply was that of a Slavish woman who had a two-year-old child who was club footed. The doctor had tried in vain to have the mother send the child to a hospital and have the trouble corrected. I became interested in the case and persuaded the mother to take the child to an orthopedic specialist, who also urged her to send the boy to the hospital and have his feet straightened.

The mother listened to the doctor and then turned to me and said, "I no send my baby for this doctor.

What you say, I better send my baby?" I told her that she should send him. With a look of trust in her eyes that I shall never forget she said, "All right, if you say, I send my baby. I send him, but for no one else, just for you."

The child had to be taken three hundred miles from home and remained there five months. During that time I corresponded with the doctor and kept the mother advised of the child's condition. Her faith all through was most implicit; and I shall never forget the gratitude of the whole family when I brought the little fellow home. His feet were straight and the family was extremely proud of him, because he had learned to speak English very well for a small child.

If space permitted me to tell of all my experiences I could give instance after instance that would show the confidence and gratitude of these friends who have come from across the waters. One Italian woman whom I assisted through a long siege of sickness and need, showed her gratitude by presenting me with the only thing of value that they had in the house. It had been the gift of a priest and was highly prized by the whole family. I tried to persuade them to give me something of less value but found that I could not refuse the gift without deeply wounding the feelings of all. The mother, with tears in her eyes said, "You do everything for me; I give you only my best."

I am sending a recent photo (Fig. 1) of the home of one of our Slavish families. It is not claimed that all foreign homes are as well kept as this one, but many of them are. I chose this one as an illustration, because the woman was thirty-two years of age before she left the old country, and, the older people are, the harder it is for them to change their habits of living.

FIG. 2. LIVING ROOM AND BEDROOM IN THE SAME SLAVISH HOME

In Fig. 2 is shown the living room and the bedroom of the same house. These pictures were all taken about 9:30 one Monday morning. The woman did not know that I was coming or would take the pictures and the

FIG. 3. (1) FOREIGN CHILDREN WITH LIBERTY BONDS.

(4) COMMUNITY BAND AT PRIMERO, COLO.

house was not staged for the occasion. I asked her not to change a thing and she continued her washing while I took the pictures, which speak for themselves and show that, in her fifteen years of residence in this country, many American ideas have been adopted. It is quite a step in advance when foreign-born people discontinue raising vegetables in the front yard and make a lawn and plant flowers.

As a rule the beds of the foreign people are very clean. If you have occasion to visit a home where there is sickness you will usually find the bedding spotless, and the sheets and pillowcases trimmed with hand-made lace. I do not claim that this is always the case; but it is true in the majority of their homes. There is a well known American type of family that is far less particular than the average foreign woman.

Since the war started, we have found these people very ready to respond to every call made upon them. Their donations to the Red Cross, Y. M. C. A. and other war organizations, their subscriptions to Liberty Bonds and War Savings and Thrift Stamps have been most generous, and show that they have a real interest in their adopted country.

Community Work Conducted by the Colorado Fuel & Iron Co.

During the last four years I have had charge of girls' summer camps. Over four hundred girls have attended these camps, and over sixty per cent. of them came from foreign families. It has been remarkable how quickly these girls avail themselves of every opportunity offered them and the improvement they make is very rapid. They do not want to appear different from the American girl, and are ever on the alert to imitate them. They are always ready to help, in work or play, and have what we consider a good camp spirit.

In Fig. 3 is shown a group of children, only one of whom is American. These children own over $1200 worth of thrift stamps and war-saving stamps. One child alone whose mother is German and father Italian has filled three books with these stamps and has now started on her fourth book.

In the next picture is shown another group of foreign children who have collected the pile of rubbish shown, from their yards and the street, in an effort to clean up the camp on what was known as "clean-up day."

In the third picture is shown the dental nurse of the Colorado Fuel & Iron Co. instructing a class of six children—two Americans and four foreign—in the proper care of their teeth. Notice the likeness of dress in the foreign and American children.

In the fourth picture is shown the community band of the Colorado Fuel & Iron Co., at Primero, Colo. Many of the band members are foreigners by birth. The company does all in its power to encourage every department of community work and much success is attending its efforts.

Let me say, in closing, that I do not wish to create the impression that community work among foreigners is always easy and that one meets with no difficulties. At times, I become discouraged and wonder if it is worth while. But, in every walk of life, the things that are worth doing require perseverance and the ability to overcome obstacles.

Habits that have been long formed are hard to change, and we must not expect people coming from other countries to immediately forsake all their customs and habits of living. The process will be slow and gradual; but in time we shall reap the harvest if we faint not. The spirit with which one goes into this work and the amount of tact he or she possesses, together with the ability to read human nature are the determining factors that govern the degree of success a worker attains in this service.

Miriam C. Dawley,
Community Secretary, Colorado Fuel & Iron Co.
Primero, Colo.

Reminiscences of a Life-Long Friend

I was deeply interested in reading the obituary notice of W. J. Murray, vice-president and general manager of the Victor-American Fuel Co., which appeared in *Coal Age*, Oct. 3, p. 643, and beg to add a few words recalling a friendship the memory of which forms some of my pleasantest recollections.

Mr. Murray's death occurred while I was away on a trip in the northwest where I had little opportunity to see the daily papers. The notice of his demise published in *Coal Age* is the first intimation I have had of the sad event, which brings to me a flood of memories.

It so happened that I was resident engineer at Sopris, Colo., when Mr. Murray entered the service of the Colorado Fuel Co., of which J. C. Osgood was president. The company had leased and was operating the Smith anthracite mine, up the mountain, 4 miles from Crested Butte. There I wintered 1887-8, going to Sopris in the spring of 1888, to take charge of the construction of a permanent tipple and coke ovens that the company were to build at that place.

The superintendent at Sopris, whose name I do not recall, had formerly had charge at the Crested Butte mine where Murray was firebossing, and in that way had formed his acquaintance. Later, as the Sopris mine developed, Murray was made mine foreman at Sopris. That was in the summer of 1888 (not 1887 as stated in the obituary mentioned). A few months after Murray arrived, the superintendent took sick and died.

Rapid Advancement of a Self-Made Man

The new tipple was now finished and Mr. Murray was appointed superintendent of the Sopris mine. I recall, now, the rapid development that took place, and how the output soon reached 1200 tons a day, which was then considered an enormous showing.

Murray was working very hard at that time to achieve an education; and I suppose, because I helped him a little in certain ways, he became quite attached to me and I to him, owing to the characteristics you have so vividly described. If I remember correctly he had had little or no opportunity of attending school when a boy and I think it was not until after he was married that he could write his name. I believe he gave credit to his wife for inspiring him to take up some studies, and he worked at them hard. At the time when I first knew him, he was quite a student of mining literature.

I recall a rather amusing episode, which he often related with considerable glee, of how he arrived in

this country, at Baltimore, as a green countryman. On coming off the steamer, he saw for the first time a large and able bodied negress who so amazed him that he stopped and stared open-mouthed at her until she gave him such a slap on the jaw that it knocked him over. Like nearly all old country miners he had, in his youth used liquor freely. As many know, it was a custom for men to drink Saturday and beat their wives.

As I stated before, Mr. Murray had become a fireboss at Crested Butte and evidently a very efficient one, as that was a very gaseous mine. At one time, I think he had been drinking and was discharged. A bad gas explosion occurred some days later, which struck home to him and he made a resolution not to drink liquor in excess again, and so far as my knowledge goes he kept his resolution faithfully. As he was considered a most able man, the old Colorado Coal and Iron Co. reëngaged him as fireboss and subsequently he went to Sopris.

The Test That Comes to the Superintendent

Murray's first trial came soon after his appointment as mine superintendent, at Sopris. There was a strike that threatened to be bad. From the company's standpoint, it was unjustifiable. It was thought to have been started by the "Molly McGuires." One of the episodes occurred when Murray, resenting an insult from a foreign miner, leaped on him, in the office; the miner shot at him but missed and Murray knocked him out. It was a rough and ready part of the country at that time.

I was thrown very closely in touch with Murray, not only during my regular connection with the Osgood interests, in Colorado, but subsequently when I visited New Mexico and Colorado, on consulting work. He was one of the squarest, true-blue men I have ever met and it is a sad thought to me that I will not see him when I go west, as formerly.

George S. Rice,
Chief Mining Engineer, Bureau of Mines.
Washington, D. C.

Cost Accounting in Mine Haulage

Letter No. 1—In connection with the discussion of the proper accounting of supplies and materials used in the mine, and the excellent letter on that subject, by J. Kenvin, which appeared in *Coal Age*, Oct. 17, p. 754, permit me to suggest that a like consideration of the costs of maintaining and operating mine haulage systems would prove equally interesting and helpful.

We read a lot about haulage systems and haulage costs, but we seldom see a mine haulage system fully analyzed and the cost of its operation fully described. I fear that oftentimes charges are made against the haulage account that logically belong elsewhere.

It is much the same as with a manufacturer or merchant who has no regularly laid out system of accounts, but charges a certain expense to one account, one month, day or week, and the the next time it appears in another column. As a result, the manufacturer or merchant never really knows the unit cost of his product or the turnover of the goods.

Again, the various items, in mine haulage, are considered in a different light by different operators, or I should say, bookkeepers, and a burden is thrown on some divisions that should be borne by other activities.

For example, take the question of what power is consumed in the main line haulage, extending from the different gathering points to the tipple or shaft bottom. Some companies simply guess that a certain percentage of their power is consumed in that service, and the assumed percentage may be low or high.

Others try to approximate this charge or cost of hauling the coal from the gathering stations to the shaft bottom or tipple, by estimating on the rated consumption of the motors. That method, at best, is a wild guess, as no account is taken of the line and feeder losses and the return losses are a forgotten item.

Some companies have realized the tremendous losses occurring in the return, and are attempting to bond the rails which will assuredly save a great deal of money and help to keep the coal moving much more steadily. But the vast majority of companies have no definite idea as to the several items of cost.

It is possible to figure the cost of charging storage-battery locomotives, and the cost of repairing them and trolley locomotives; but how many keep an accurate record of the labor, material and other sundry charges that go to make up the total upkeep cost?

The wages of the motormen are easily computed and charged, but few companies indeed actually charge to their haulage account the upkeep of cars, track and locomotives, cost of lubricant and the oilers' wages. When all these are combined properly, the charge assumes a very pretentious size and is one that is vitally associated with the cost of production.

Haulage Charges Properly Classified

Haulage charges should be divided into gathering and main-haulageway service. One can be excessive, carrying the burden of the other. Both, however, should be very vital to every man who is producing coal, and yet how many have even a slight knowledge of these respective costs? A searching investigation, would, I am afraid, disclose a woeful lack of definite knowledge, and no industry can properly function or produce adequate returns unless every expense item is known and, what is more important, really appreciated.

A good system of haulage accounts, it must be admitted, will not remove the losses due to the stalling of motors by trips of stiffly running, plain-bearing mine cars; or the excessive labor due to bad tracks, or rails that are too light, broken wheels or axles, which cause wrecks; but the right kind of accounting system will enable the progressive operator to save many petty losses, as well as major ones; and the knowledge to be gained by a study of a chart of haulage costs is almost beyond imagination.

I must confess to being greatly at sea, after hearing many ideas as to what should comprise legitimate haulage costs; and I sometimes believe that there cannot be a perfect or universal system, because the conditions are so different in every mine in respect to mileage, grades, etc.

There are, unquestionably, some sound rules that have been subjected to the rigid examination of men who know what they are doing; and some sheets or cards have been designed to cover the subject fully, with necessary report blanks for subordinates to use when submitting their reports; but who has ever seen them published? Very few of us, I am sure. This is a subject

that can and should be discussed, in the columns of *Coal Age*, by superintendents, electrical engineers, and last but not least, by the auditors of our companies.

Auditors have a vast fund of information that would be helpful to many. Their knowledge and experience, coupled with the knowledge and experience of the actual operating officials, who are face to face with these problems, day in and day out, would make very interesting reading and fulfill a long felt want in coal mining literature.

I have written at such great length, because this subject is one of the most vital with which the coal industry has to contend; and a thorough knowledge of all of the conditions and circumstances that affect it would very largely tend to put the company on a better basis.

————, W. Va. PROGRESSIVE.

The Miner and Safety

Letter No. 2—I was pleased to read the excellent letter of M. H. G., *Coal Age*, Oct. 10, p. 707, in which he illustrates in a vivid manner the little regard that the practical miner has for his own safety and describes how such a one "passes up" things that are really dangerous, depending on his mining experience to carry him through safely. I was glad to see that the writer of the letter agreed with my suggestion that it is the experienced miner who is the most frequent victim of serious accident. In many cases, the practical miner resents being told what he must do to make his place safe and, as a result of his independence and disregard of instructions given him by the foreman, he is often fatally injured.

The safety of miners is a most important topic, and anyone who is interested in the work of coal mining should concentrate his thoughts upon what relates to safety, as much as he does upon the production of coal. As we all know, accidents are unavoidable in many cases. However, a large proportion of the accidents due to falls of coal and rock, at the face, can be avoided by the constant and close inspection of each working place by the foreman and obedience to his instructions on the part of the miner. The main point, for a person who has charge of men, is to familiarize himself with each and every cause of accident and then drive them home by impressing them on each man working under him. Foresight on the part of the foreman and the miner, is one of the chief elements relating to safety.

Contempt of the Experienced Miner for Safety

It would be amusing, if it were not for the serious results that follow, to pass along a gangway where probably 20 or 30 miners are working, and listen to the remarks of the practical miner regarding another who has less experience but who exercises more care to keep himself safe. One hears the remark, "Yes, John is a pea-coal miner; he's a big greeny." But, going into John's place, you find him hard at work, with a good prop standing near him, which he has just set to give better support to the roof above him. Unlike the practical miner who ridiculed him, John is willing to listen to instructions and obeys them promptly.

Ask the practical miner to sound his roof, and his answer is, "It's as safe as if you were outside." On close inspection, however, the foreman discovers a small crack, which justifies his suspicion aroused by the looks of the place. Yet, sounding the roof with the pick gives no indications of its being unsafe, and you have to insist on the man stopping work and setting a post with a good cap crossing the crack in the roof at right angles. A few more cuts taken from the face prove that the foreman's foresight saved the miner.

Causes of Accidents That Should Be Avoided

Let me refer, here, to a few conditions that lead to accidents. For example, obeying the instructions of the foreman, a practical miner reluctantly sets a post in the center of his place. A little later, the post is discharged by a blast, and the miner, on returning to the face, starts to load his coal and neglects to reset the post, until he thinks the foreman will be around again. But, before that time, the unfortunate is caught by the fall of the loose slab.

The places that are usually the hardest to keep safe are those where the roof is a slab formation, and the slate falls in pieces from 6 to 10 in. in thickness. Such a formation is what is known to the miner as "a rider." I have watched men of many years' experience work under such top for a distance of 6 or 8 ft. without attempting to protect themselves.

Told to stop work and take the piece down, the miner invariably replies, "I just tried it and can't get it down." You answer, "Well, try it again." To satisfy you, he prods the piece a little, but makes no great effort to loosen it. A little assistance of the foreman and the slate falls with a heavy crash. Notwithstanding the fact that you have saved the man from possible death, he grumbles that you have dirtied his loose coal, stating that it will take some time to clean it, which is his only excuse for taking the chance he did.

Foreman Insists and Saves Miner

Just recently, I visited a miner's chamber and found that he had taken two cuts from the face, which left a piece of rock 8 in. thick, 5 ft. wide and 9 ft. long, unsupported above where he was working. My request that he should sound the roof brought the reply, "Oh, it's all right; I will pull the piece down when I take the next cut." The foreman insists, "No, try it now, get your drill." The result was that the piece fell heavily on the first touch or pull. Questioned as to whether he had tried it before, the man replied, "Yes, and it was all right." That man had 12 years of mining experience and, had he been caught, the foreman or assistant whose duty it was to inspect his place would have been held responsible for the accident.

Another condition requiring close inspection is where the miners are required to set their posts from 4 to 6 ft. apart, along the face. The practical miner is prone to be careless and will often advance more than this distance, without setting any temporary supports. In that case, the chances are that he may be caught by a slip in the roof that does not appear until too late and the fall takes place, catching the miner.

Let us hope that the discussion of these questions in *Coal Age* will make the practical miner more careful for his own safety. Practical experience is the most essential element in the safe mining of coal; but the miner must coöperate with his foreman.

Kingston, Penn. LEWIS R. THOMAS.

INQUIRIES OF GENERAL INTEREST

Reversing an Electric Motor

Some trouble with the electric generators at our mines recently started a dispute between the mine electrician and myself as to whether reversing the leads on the switchboard at the power house would reverse the direction of the motor on the locomotive in the mine. The power appeared to be traveling in the rails instead of on the trolley wire, which seemed to be the return. The electrician claimed that changing the switchboard leads at the power house would change the direction of the current in the circuit and reverse the motor in the mine, while I held that it was necessary to use the reversing switch on the machine, which would change the flow in the field in order to reverse the motor. Kindly settle our dispute by explaining fully what is required to reverse a motor in a mine.

East Millsboro, Penn. ASSISTANT FOREMAN.

An arrangement that would permit the power to travel on the rail and the current return over the trolley wire is unusual and poor. In order to make

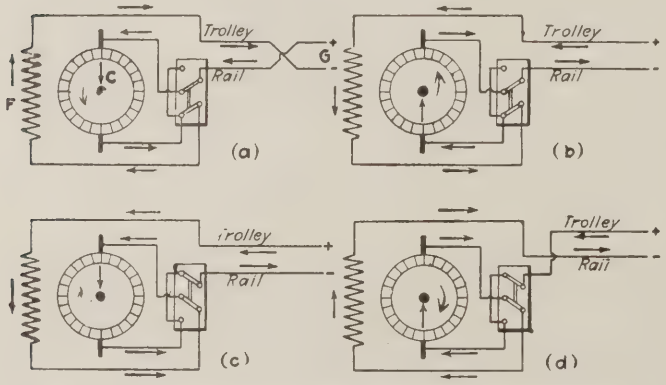

FIG. 1. ILLUSTRATING REVERSING A MINE MOTOR

the situation clear, we have drawn Fig. 1, showing four arrangements, *a*, *b*, *c*, *d*, which we will explain.

The first arrangement (*a*) shows the original condition described in the inquiry, where the power is traveling on the rail and the current returning by the trolley wire. The letters in this figure apply to all the figures alike; *G* indicates the leads at the switchboard of the generator in the power house, the positive lead being the power line and the negative one the return; *C* is the commutator of the armature, *F* the field and *S* the reversing switch of the motor. Observe carefully the direction of the current passing through the armature and the field, as indicated by the arrows.

The second arrangement (*b*) shows the change that takes place when the current is reversed at the power house. The power is now traveling on the trolley line, as it should, and the rail is the return. Observe that the position of the reversing switch on the locomotive has not been changed. Changing the leads at the power house has changed the direction of the current throughout the entire circuit, including the flow through the armature of the motor and the flux in the field; but the direction of the rotation of the armature, as indicated by the arrows, is the same as before.

The reason the motor is not reversed is that the flow through the armature and the flux in the field have both been changed, and counteract each other. In order to change the direction of rotation of the armature it is necessary to change the direction of either the flow of current through the armature or the flux in the field, but not both.

In the third arrangement (*c*), the current from the generator follows the trolley line and passes through the field of the motor before reaching the reversing switch on the locomotive. This switch is now reversed, which changes the direction of the flow of current through the armature only, and causes it to revolve in the opposite direction from its previous rotation. Notice, however, that the flux in the field remains unchanged.

The fourth arrangement (*d*) is drawn simply to show a different connection from that just described. Here, the power passes from the trolley line directly to the reversing switch of the locomotive and through the armature, before reaching the field, which has the effect of altering the flux in the field, while the flow of current through the armature is the same as that in the second case. This also reverses the rotation of the motor, as indicated by the small arrow.

Reference to Fig. 2 will make clear the fact that changing both the direction of flow in the armature and the flux in the field will not alter the direction of motion, or reverse the motor. In the figure, the thumb and first two fingers indicate respectively the direction of rotation of the armature, direction of the flux or lines of force generated in the field and direction of the current in the armature, the left hand being used.

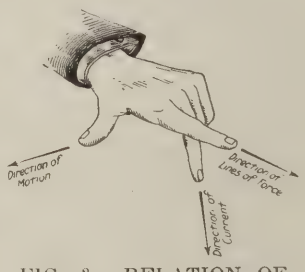

FIG. 2. RELATION OF THREE FACTORS IN ELECTRICITY

Now, it is clear that if the hand be turned about the thumb as an axis, through an angle of 180 deg., both the direction of current in the armature and the flux in the field will be changed, while the direction of rotation remains the same. On the other hand, let the hand be turned about either of the fingers as an axis, through 180 deg., so that either the flow of current through the armature or the lines of force in the field is changed, but not both, and the effect is to change the direction of rotation, as indicated by the thumb.

The right hand is used when it is desired to illustrate this principle in reference to a generator in which the construction is identical with that of a motor but the conditions of operation are reversed.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—What are the effects of unequal expansion and contraction in a boiler?

Ans.—Unequal expansion or contraction in the boiler plate causes an excessive strain to be thrown on certain parts, which may cause rupture by the shearing of rivets or open the seams in the boiler plates. At times, bulging or buckling of a plate may result from the undue strain thrown on that part of the boiler.

Ques.—What care should be taken of boilers to secure the best results?

Ans.—Steam boilers should be thoroughly cleaned, at regular intervals, and all sediment and scale removed. Where the feedwater contains sediment, the boiler should be blown off regularly, at sufficiently short intervals to prevent the accumulation of the sediment in the bottom of the boiler. The smoke flues should also be cleaned regularly and kept free from deposits of soot. All parts of the boiler should be inspected at frequent intervals. The boiler should be fired in a proper manner and the water level never allowed to fall too low and expose the fire plates to injury through overheating. The feedwater should be heated before being admitted to the boiler.

Ques.—How would you fire a boiler to get the best results from it and from the coal used?

Ans.—Best results are obtained when firing is performed by what is known as the "coking method." In this method, the fresh coal is piled up on the front half of the bed and allowed to become well ignited before it is spread over the remaining surface of the fire. By this means, the gases are distilled from the fresh coal and pass back over the fire. In this way, a more even regular heat is maintained in the furnace than when the fresh coal is spread over the entire surface of the bed, which would dampen the fire and reduce the temperature in the furnace. In the coking method, the gases distilled from the fresh coal at the front of the furnace, meeting with the hot air that rises through the bed of coal, are burned and maintain a high temperature in the furnace.

Ques.—State generally what is meant by expansive working and condensing, as applied to steam engines.

Ans.—The steam works expansively in the cylinder of an engine when the valve cuts off the supply of steam before the stroke is finished. The expansion of the steam remaining in the cylinder then performs the work, during the remainder of the stroke. This is known as working the steam "expansively."

A steam engine may be either noncondensing or condensing. In the former case, the engine exhausts into the atmosphere, and the movement of the piston is then opposed by the atmospheric pressure. In a condensing engine, on the other hand, the exhaust steam passes into a condenser where it is condensed and produces more or less of a vacuum, whereby the back pressure on the piston is reduced during the return stroke.

Ques.—The piston speed of an engine is 600 ft. per min.; what is the length of the stroke if the engine is running at 150 r.p.m.?

Ans.—In this case, the piston travels $600 \div 150 = 4$ ft. during each revolution of the engine; and, since the engine makes two strokes each revolution, the length of the stroke is 2 feet.

Ques.—The diameter of an engine cylinder is 10 in., the length of stroke, 15 in. The engine makes 250 r.p.m., and the mean effective pressure is 40 lb. per sq. in. What is the horsepower developed?

Ans.—The sectional area of the cylinder, in this case, is $0.7854 \times 10^2 = 78.54$ sq.in. At a speed of 250 r.p.m., the engine makes 500 strokes per min., 15 in. or 1.25 ft. long. The horsepower developed in the cylinder is,

$$H = \frac{plan}{33{,}000} = \frac{40 \times 1.25 \times 78.54 \times 500}{33{,}000} = 59\tfrac{1}{2}\ hp.$$

Ques.—What thickness of boiler plate would be required for a boiler carrying 100 lb. pressure, the diameter of the boiler being 6 feet?

Ans.—Estimating the safe tensile strength of the boiler plate at 10,000 lb. per sq. in., the required thickness of the shell, for a diameter of 6 ft., to withstand a boiler pressure of 100 lb. per sq.in. may be calculated by the formula,

$$t = \frac{pd}{2S} = \frac{100(6 \times 12)}{2 \times 10{,}000} = 0.36,\ say\ \tfrac{3}{8}\ in.$$

Ques.—How much water is evaporated per hour per horsepower, under ordinary conditions?

Ans.—In steam-boiler practice, the horsepower of a boiler is given as the evaporation of 30 lb. of water per hour from a feedwater temperature of 100 deg. F. into steam at 70 lb. gage pressure; or, in other words, 1 boiler horsepower is equivalent to $34\frac{1}{2}$ units of evaporation, which means the evaporation of $34\frac{1}{2}$ lb. of water per hour, from and at 212 deg. F.

Ques.—What is the temperature of steam in a boiler when the pressure is 100 lb. per square inch?

Ans.—The temperature of steam varies with the absolute pressure in the boiler, and must be taken from steam tables. For a gage pressure of 100 lb. per sq.in., at sea level, which corresponds to an absolute pressure of, say 115 lb. per sq.in., the temperature of the steam, as taken from the steam tables, is 337.86 deg. F.

Ques.—At what speed would you consider it desirable to hoist men in a shaft?

Ans.—The speed of hoisting men in a shaft will depend chiefly on the depth of shaft and the kind and quality of the hoisting equipment. For a depth not exceeding 100 yd., men should not be hoisted at a greater speed than 20 ft. a sec. In deeper shafts, with uptodate equipment, the speed of hoisting may reach 40 or even 50 ft. per sec., depending on the depth of the shaft, and the capability of the hoisting engineer.

COAL AND COKE NEWS

Harrisburg, Penn.

Work has been started by the Workmen's Compensation Board to put into effect plans made for the rehabilitation of men crippled or otherwise injured in industry, with a view of returning them to active work. Announcement was made on Oct. 31 by Harry A. Mackey, chairman of the board, that a personal canvass has been started of every compensation award made in recent years to find what progress toward restoration has been made by recipients of compensation. Recommendations will be made to the next Legislature by the board that at least three hospitals equipped for rehabilitation work be constructed and maintained under state auspices, one in Harrisburg, one in Pittsburgh, to take care of the bituminous field, and one somewhere in the anthracite region.

Uniontown, Penn.

Mines, coke plants and railroads have been affected by the epidemic, but the railroad situation cuts more deeply into production than the lack of labor in the mines and ovens. The traffic congestion caused by short crews reached its crest during the week, but was not cleared until the region spent an entire day in idleness and a week of reduced effort. The fuel administration records shows a total car shortage for the week of 1143, the most serious car shortage since last winter.

The total coal output of the Connellsville region for the week ended Oct. 26 is placed at 686,152 tons, of which 451,635 tons was manufactured into 301,090 tons of coke and 234,517 tons was shipped to byproduct and other industries.

Warren S. Blauvelt, coke director for the Fuel Administration, this week sounded a slogan of "Quality First" in the fuel campaign in a stirring statement issued to operators and producers of the Connellsville coke region. Mr. Blauvelt declared that inasmuch as the campaign was being waged to increase the production of iron and steel for war needs, quality must be all the more emphasized, contending that "any sacrifice of quality of coke to quantity in order to get a greater quantity will absolutely defeat this purpose." He declared that an increased production of 5 per cent. if accompanied by even a slight depreciation of quality due to excessive ash, poor structure, large percentage of fines and dirt might easily lead to a 10 per cent. increased consumption of coke per ton of pig iron and a decrease of 20 per cent. in blast furnace output.

Charleston, W. Va.

The mines of the Fairmont district are partly out of commission and production has fallen far behind. While the influenza is to some extent responsible for curtailed production, yet the operators of the district charge that the B. & O. is making no effort to supply the district with cars and that the car deficiency is now over 7000. The daily production loss is running as high as 35,000 and 45,000 tons. On last Saturday (Oct. 26) alone there were 4894 men without work and a number of the mines were shut down. Instead of getting 1400 cars a day needed for all the mines, not more than half that number of cars have been furnished recently. For the last three days of last week there were only 2263 cars furnished the district—on Thursday 965, Friday 598 and Saturday 700.

Overcoming many obstacles, the Tug River and Pocahontas district mines have managed to keep production almost up to the high point reached the latter part of September. In other words, the shipment of coal is now hovering around 465,000 tons weekly. Up to and including Oct. 25 the total shipments from the Pocahontas and Tug River districts had reached 1,407,950 tons. As the quota the two districts had expected to reach in October was 2,000,000 tons, it is hardly likely the month's quota will reach that figure, since the daily shipments are in the neghborhood of 65,000 tons only; but it is believed that had not the influenza disarranged all plans, it would have been a record-breaking production month.

Even with influenza making its appearance at many new points in the Kanawha district the mines of that district in the aggregate had a much larger output for the week ending Oct. 26 than they had during the preceding week. A better supply of cars is responsible for the increase, influenza among C. & O. trainmen having abated to some extent. The increase in output amounted to 32,000 tons, the total production for the week ending Oct. 26 being 180,363 tons as against 148,000 tons for the week ending Oct. 19. Total hours worked reached 5478. There was a shortage measured in hours of 185, due to an inadequate car supply, and a shortage of 1331 hours for which inadequate man power was responsible.

Production took an upward trend in the Winding Gulf region during the week ending Oct. 26, an excellent car supply making this possible in part, the Virginian Ry. keeping a constant stream of empties flowing into the district.

To the surprise of many there was an increased output in the New River and Winding Gulf districts last week, the increase amounting to 12,648 tons for the two districts, or in gross tons, 4562 in the Gulf district and 6711 in the New River district. This was surprising because of the prevalence of influenza in both districts, affecting in some instances 50 per cent. of the men and their families. A car shortage on the C. & O. resulted from influenza among the trainmen.

Birmingham, Ala.

Every coal company in the Birmingham district reports more or less deflection in production by reason of the influenza epidemic. Not only is the coal output being disturbed and greatly lowered, but coke manufacture, iron-making and oven operations at steel plants, machine shops and foundries are being affected. For the week ending Oct. 19, coal production in Alabama was 323,310 tons, the lowest since the Government has been checking up the work. It is expected that when the Federal figures for the week are published, the output will be still lower than that of the week previous.

A. H. Carpenter, well known in coal circles, has been appointed assistant to Production Manager H. C. Sellheimer. He will keep watch on the coke production, and will endeavor to bring about increased output at the ovens with a cleaner run of coke. It is intended to organize the forces as in the coal department, so that labor will understand the need for patriotic efforts and loyalty to the Government in striving for an increased production. There is need for every ton of coal and coke that can be manufactured for many years to come, experts say, whether or not the war ends speedily.

While the influenza epidemic hit the railroads as much as it did other corporations, the reports of the past week as to transportation business are good. Of course, the mining sections showed a considerable falling off in shipments, but these will pick up as soon as the disease has been checked.

Transportation on the Warrior River is progressing steadily enough, much bunker coal being shipped to Mobile and New Orleans, where there is an increasing demand for this kind of fuel. The trade is handicapped, however, by the lack of barges.

Victoria, B. C.

Canada's winter coal supply is receiving close attention at the hands of the Canadian Fuel Administration, at Ottawa, Ont., and it is believed that as a result of organization and of well-disseminated and educative propaganda the people of the Dominion will get through the cold months without undue hardship.

For the purpose of facilitating the equal distribution of anthracite coal in Canada during the winter a further order-in-council has been passed by the Dominion government at the instance of Fuel Controller C. A. Magrath. The regulations contained in this order are designed to prevent disproportionate deliveries of anthracite to large consumers at times when the householder cannot be supplied, the fuel controller being given the right to prohibit entirely, or to limit in any manner he may deem advisable, the use of anthracite coal in any building. This does not apply to private houses using less than 40 tons of coal annually. This law will be enforced through the fuel administrators of the various districts or, in the event of there being no such official, direct from Ottawa by the fuel controller. Infractions of the ruling may be punished by heavy penalties.

A complete list of the Provincial Fuel Administrators follows: Prince Edward Island—J. A. Macdonald, Carrigan, P. E. I. Nova Scotia—R. H. MacKay, New Glasgow, N. S. New Brunswick—Dr. James H. Frink, St. John, N. B. Quebec—H. M. Marler, Standard Building, Montreal, P. Q. Ontario—R. Home Smith, Harbour Commissioners' Building, Toronto, Ont. Manitoba—J. A. Macdonald, Winnipeg, Man. Saskatchewan—T. M. Molloy, Regina, Sask. Alberta—John T. Stirling, Edmonton, Alta. British Columbia—N. Thompson, Vancouver, B. C.

PENNSYLVANIA

Anthracite

Wilkes-Barre—W. S. Sprague, of this place, has submitted to the Department of Mines of Pennsylvania for its approval a sample of a specially treated paper for brattice use. It is claimed that this paper will not burn and is being successfully used in a number of mines.

Minooka—The Lackawanna Coal Co. has placed a force of men at work making repairs to St. Joseph's Hall here, which was recently quite badly damaged as a result of mine settlings. When the repairs are completed and the heating plant is put in condition the building will be used as an emergency hospital for miners and their families.

St. Clair—Cheap fuel for a century to come is in prospect for the Reading Ry. as a result of experiments successfully completed recently on the run between St. Clair and Philadelphia. Locomotive 1717 was fired for a series of runs with a mixture of culm and bituminous, in the proportion of 65 per cent. for the latter and 35 per cent. of anthracite culm. The combination worked so well, it is stated, that steam pressure of 210 lb. was maintained for the entire run. The locomotive was equipped with an automatic stoker, and the officials, to carry the test still further, will now try the mixture hand-shoveled into the engine firebox.

Bituminous

Somerset—H. L. Sellers, of Confluence, has leased and is operating the mine near Draketown.

Savan—A new mine is being opened on the Lowry farm here by Frank Lowry. The coal will be dumped over the new tipple of Lowther & Davis.

Homer City—A switch connection has been made by the Pennsylvania R. R. with the siding of the Myvan Coal Co. just south of Horner City. The new company has purchased about 100 acres of the Upper Freeport coal and it is reported will develop it at once. No construction work, outside of the siding connection, has been started as yet.

Indiana—The Two Lick Coal Co. has abandoned the sinking of its shaft on the property near Indiana until after the war, owing to the scarcity of labor. The shaft was sunk about 50 ft. and had about 16 ft. to go to the coal when abandoned. The new operation was to supply the commercial and domestic coal for Indiana which is now hauled from Yellow Creek and shipped in by rail.

WEST VIRGINIA

Logan—On Nov. 4 the MacBeth Coal Co. began shipping coal from its plant on Rum Creek in the Logan field. The company will take coal from the Eagle Seam, having a 5-ft. vein in which to operate.

Clay—So hard were the mines of the Elkland Coal Mining Co. at Clay hit by the influenza that not enough physically able men were left to man the mines, and consequently the mines were shut down entirely.

Bluefield—A new tipple has recently been put up by the Camella Red Ash Coal Co. at Drill. The same company has also erected a number of houses for miners and a store building. L. G. Little is in charge of operations as superintendent.

Bluefield—Within the last few months the Banner Raven Coal Corporation, with a plant at Drill, has not only put up a new tipple but has also erected 53 dwellings for miners and a clubhouse. It is also adding to the number of miners' dwellings built.

Bluefield—A siding is being laid by the Garden Coal Co., at Drill, to its new permanent tipple. Though the company, of which C. W. Steele is general manager, began shipping coal last February, it was not until recently that the permanent tipple was completed.

Olcott—Construction work on the plant of the Newcourt Coal Co., near here, in the Coal River field, is nearing completion. Coal will be taken from both the Black Band seam and the No. 2 Gas seam. Preliminary work at the company's plant is in charge of W. J. Newenham.

OHIO

Oreton—L. D. Binyon and James Hogan two brick men of Chicago, are developing a stripping operation at Oreton on the Hocking Valley Ry., in Vinton County. A track is being built and a contract has been awarded for a steam shovel with a capacity of 400 tons daily. A part of the coal will be sold through the Columbus Fire Brick Co., Columbus.

INDIANA

Clinton—An explosion in the Vermilion Coal Co.'s mine, northwest of Clinton, seriously burned James Hinkle and James McQueen, shotfirers. It is believed, however, that both men will recover.

KENTUCKY

Madisonville—The St. Bernard Mining Co. is well along with the construction of its new power plant, which will cost more than a half million to complete, and which will furnish power and light for eight mines and a number of towns. The plant will be at Loch Mary, near Earlington, and will supply power to the Fox Run, St. Charles, South Diamond, Shamrock, Luten and Victoria mines, serving two or more mines at some of these points. The miners' homes will be taken care of and light furnished for residences in the towns named.

ILLINOIS

Benton—The new coal washer of the United States Fuel Co. at the Middlefork mine was tested out a few days ago in the presence of all of the company officials from Chicago. It cost $500,000 and is said to be the largest in the world.

Carlinville—Coal was struck in Mine No. 3 of the Standard Oil Co., at Schoper, seven miles east of here, recently, at a depth of 315 ft., 74 working days after the work began. This is said to be a record. The first load of coal was brought to the surface the next day.

Pinckneyville—The body of Joseph Neising, who was drowned in the Gordon mine 39 years ago, was recovered from the mine on Oct. 26, in comparatively good condition, and the funeral was held next day, and was attended by his five children. Neising was drowned Jan. 5, 1880, when Beaucoup Creek overflowed and flooded the mine. All the miners but Neising escaped. No attempt was made until recently to pump it out. When the water was removed Neising's body was found near the air shaft. The cold water had preserved it.

Belleville—A standing shot at Eldnar mine Monday, Oct. 28, caused a fire which was only extinguished after an all day fight.

Miners employed at the Richland, Wilderman and St. Clair mines, on the Illinois Central R. R., have petitioned the Federal Railroad Administration for a train to carry them to and from their work. They say that unless transportation is provided they will have to seek work in other mines.

A coal company which leaves an open keg of powder in a shed is responsible if a pair of meddlesome boys find it and set it off, according to a decision in the Belleville Circuit Court. The Egyptian Coal Mining Co. of Marissa, Ill., was required to pay $1750 for the death of one of the boys and $2000 for injuries to the other.

COLORADO

Trinidad—William Caddell, who with Henry Carlson, of Walsenburg, was part owner of the Hezron mine in Huerfano County, was instantly killed on Oct. 21 by an explosion of gas. Five others were injured, two perhaps fatally. The mine was a former Colorado Fuel and Iron property and was leased by Caddell and Carlson.

Foreign News

Victoria, B. C.—When Hon. Martin Burrell, Minister of Mines in the Dominion government, was in British Columbia recently a delegation of Vancouver Island residents waited on him with regard to the interests of settlers interested in the coal rights of the island. They wanted some statement from the minister as to whether, should the British Columbia government reënact the Settlers' Rights Act of 1917, the Federal authorities would refrain from disallowing it again. Mr. Burrell could make no definite statement but assured his petitioners that he appreciated the importance of the matter from the viewpoint of the settlers, involving as it did title to a considerable proportion of the coal resources of Vancouver Island. He agreed that all those interested were entitled to the fullest hearing by the Dominion government should the matter come up for reconsideration. The Settlers' Rights Act, it may be explained, gave the settlers within the Esquimalt & Nanaimo Ry. belt a specified period in which to make claim to the coal rights within the limits of their property, they then being granted title to the coal, if able to substantiate their claims. The coal areas in question, or at least most of them, now are owned by the Canadian Collieries (D) Ltd.

Personals

George Love, formerly with the Jefferson and Clearfield Coal and Iron Co. at Ernest, Penn., has been made mine foreman of one of the mines of the Coal Run Mining Co. at McIntyre, Penn.

J. H. Schroeder, formerly secretary of the Rutledge & Taylor Coal Co., of Chicago, Ill., has resigned his position with that company, effective Nov. 1, and has accepted the positions of treasurer of the Mason Coal Co., and assistant treasurer of Nokomis Coal Co., with offices at 1380 Old Colony Building, Chicago, Ill.

C. L. Huntzinger, recently connected with the Robins Conveying Belt Co., has accepted the position of mining engineer with the Valier Coal Co., Valier, Franklin County, Illinois. Mr. Huntzinger has developed a method of mining whereby it is expected that the recovery of coal in that district will be largely increased.

Charles G. DuBois has been elected vice president of the Western Electric Co., Inc., of New York, N. Y. Mr. DuBois entered the employ of the company in 1891 at its New York office and occupied successively the positions of chief clerk, secretary and supervisor of branch houses. Mr. DuBois is 48 years of age and was graduated from Dartmouth College in 1891. He resides in Englewood, N. J.

Walter McNichol, of Scranton, Penn., formerly state senator and one of the supervising inspectors of the State Department of Labor and Industry, was on Oct. 29 appointed as chief of the Bureau of Inspection and ex-officio acting commissioner of Labor and Industry during the absence in military service of Col. John Price Jackson. Mr. McNichol succeeds Lew R. Palmer, of Pittsburgh, who has retired.

Obituary

W. J. McIninch, superintendent of the Knoxdale mines of the Loash Coal Co., died Oct. 18 from pneumonia, superinduced by influenza. His home was at Knoxdale, Penn.

John H. Williams, of Pittston, Penn., general inside foreman at the Stevens colliery of the Lehigh Valley Coal Co., died on Oct. 29, following an attack of influenza. Only a week before a son of the deceased was claimed by death. Mr. Williams is survived by his widow and four children.

Frank A. Kearns, superintendent of the United States Coal and Coke Co.'s operations at Lynch, Ky., died at Pittsburgh, Penn., following an illness of five days, dating from the time he left Middlesboro to attend the funeral of Superintendent W. W. Harding, of the company, at Pittsburgh. Mr. Kearns was born in East Liverpool, Ohio, and was 31 years of age. He had been in charge at Lynch about a year.

Coming Meetings

American Society of Mechanical Engineers will hold its annual meeting Dec. 3-6 in New York. Secretary, Calvin W. Rice, 29 West 39th Street, New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 4 and 5 in Pittsburgh, Penn. Secretary, H. D. Mason, 911 Chamber of Commerce Building, Pittsburgh, Penn.

American Institute of Electrical Engineers will hold its 343d meeting Nov. 8, at 8:15 p. m., in the Engineering Societies Building, New York City, under the auspices of the industrial and domestic power committee. Secretary, F. L. Hutchinson, 29 West 39th Street, New York City.

Industrial News

Springfield, Ill.—The Chicago, Wilmington & Franklin Coal Co. has been sued by Margaret Furry for $10,000 for damage to her land through the failure of the company to place supports in entries when it took out the coal. She alleges that the surface subsided.

Bluefield, W. Va.—The Sandy Ridge Coal Co., operating at Drill, in Southwestern Virginia, will hereafter conduct its operations under the name of the G. R. Carter Coal Co., with G. R. Carter as general manager. A new tipple has recently been built by the company.

Charleston, W. Va.—Under a modification of the zoning regulations nut and slack coal for steam purposes produced in the Coal River, Guyan Valley and Kenova Thacker districts may be shipped into the Lower Peninsula of Michigan.

Uniontown, Penn.—A deed conveying 63 tracts of the Pittsburgh vein of coal to the Pittsburgh Coal Co. has been placed on record by C. E. Lenhart and others, trustees for I. W. Semans, bankrupt. The tracts are located in West Bethlehem, Smith, Strabane and Amwell townships, Washington County. The consideration named was $766,870.75.

Chicago, Ill.—The Chicago Pneumatic Tool Co. announces the appointment of A. M. Brown as district manager of sales, 1740 Market St., Philadelphia, succeeding G. A. Barden, who remains in Philadelphia as sales representative for the company. For some time past Mr. Brown has been located in the New York offices of the company as assistant manager of the compressor sales division.

Charleston, W. Va.—It is reported that Henry Ford has purchased the properties of the Marmet Coal Mining Co., Kanawha County, and the Otto Marmet mines, Putnam County. It is said the entire output of both operations will be used exclusively for the Detroit and other plants now operated by the Ford company. Controlling interests of both mines were owned by Marmet Brothers, of Cincinnati. The two operations have a daily output of 120 tons.

Toledo, Ohio—Despite the falling off in production in Ohio and West Virginia, due to influenza, activity at the docks at the lower lake ports has been marked. During the week ending Oct. 26 the Toledo & Ohio Central docks loaded 78,000 tons, as compared with 89,000 tons during the previous week. The total for the season is 1,952,000 tons. During the same week the Hocking Valley docks handled 259,572 tons, as compared with 151,780 tons during the previous week, making a total of 4,494,005 tons for the season.

St. Louis, Mo.—Fuel Administrator Crossley and the ten district engineers of the Missouri Fuel Administration had a meeting last Friday at the offices of the St. Louis Fuel Committee and decided upon a basis of classification of the questionnaires sent to industrial concerns last summer. There are to be five classes, based on efficiency and degree of essentiality. Those in the least efficient classes will be given the lowest rank. Those who failed to return the questionnnaires will find themselves without coal if a scarcity occurs.

Uniontown, Penn.—F. E. Markell, of Connellsville, Penn., a minority stockholder, has asked for the appointment of a receiver for the Pennsylvania Fuel Co., with offices in Uniontown. He also asked for an injunction restraining the payment of alleged exorbitant salaries to S. A. Carson, of Greensburg, and G. M. Hochheimer, of Uniontown, whom he charges with a conspiracy "to appropriate to themselves the profits and earnings of the corporation." He claims that for 1917 Carson drew a salary of $14,750 and Hochheimer $22,000 during the same period.

MARKET DEPARTMENT

Weekly Review

No Fears Entertained So Far As Soft Coal Is Concerned—Influenza Still Limits Production —Large Stocks of Soft Coal Reported at Mines—Many Operations Closed for Shipping Dirty Coal—Anthracite Still a Source of Worry—Small Sizes Plentiful.

SO FAR as bituminous coal is concerned, there is no immediate cause for anxiety. True, the ravages of the influenza epidemic in the coal-mining sections continue to limit production, but so large a quantity of soft coal has been accumulated in storage piles that no shortage is feared in any quarter. In fact, a surplus of coal has been reported from practically all mines west of Pittsburgh, this unusual condition being attributable largely to the possibility of an early peace and partly to the exceptionally moderate weather which has prevailed throughout the country for the past month or more. Developments in the war situation change with such rapidity that manufacturers of certain classes of goods will not keep their reserve stocks of coal at the permissible maximum limit. If, however, Germany should decline to accept the terms of the Allies' armistice, it is expected that the surplus now existing will soon disappear.

During the week ended Oct. 26 the output of soft coal is estimated at 11,215,000 net tons as compared with 11,524,000 net tons for the week ended Oct. 19. The downward trend is traceable directly to the influenza epidemic. Indications point, however, to a return of the gratifying tonnages of a month or so ago, as the disease is now on the wane.

With the urgent need for quantity production of soft coal now somewhat ameliorated, the Fuel Administration is again turning its attention to quality. During the week ended Oct. 28 orders were issued to 13 soft coal mines prohibiting them from mining or shipping their product as it was of an inferior quality. This makes a total of 99 mines closed since the Fuel Administration inaugurated its campaign for clean coal.

Anthracite output during the week ended Oct. 26 is estimated at 1,714,000 net tons, which is exactly the same tonnage produced during the week ended Oct. 19, but 339,000 net tons below the output of the corresponding week of 1917. The increase in wages which went into effect in the anthracite mines on Nov. 1 will undoubtedly bring back many of the mine workers who left for other industries because of higher wages. With added man power and no epidemic to contend against, an improvement in output can be expected shortly.

While there exists a scarcity of the domestic sizes of anthracite, there is an abundance of the small coals available. In some instances shippers are reducing their prices in order to dispose of their stocks of rice and smaller coals. Household consumers who have not as yet received their quota of hard coal would do well to look into the possibility of utilizing these small sizes, as it has been demonstrated that they can be successfully burned in household furnaces.

WEEKLY COAL PRODUCTION

The influenza epidemic continued to limit production of bituminous coal during the week of Oct. 26, and preliminary estimates place the output at 2.7 per cent. below the week preceding. The output during the current week (including lignite and coal coked), is estimated at 11,215,000 net tons as compared with 11,524,000 net tons during the week of Oct. 19 and 10,804,000 net tons during the corresponding week of 1917. The average production per working day during the week of Oct. 26 is estimated at 1,869,000 net tons and while lower than the preceding week, estimated at 1,921,000 net tons, exceeded daily production during the week of Oct. 26, 1917, estimated at 1,801,000 net tons, by 3.8 per cent.

The decline in production during the past few weeks now makes necessary an average daily production during the balance of the coal year of 2,047,000 net tons, an increase over the daily requirements of approximately 1.6 per cent. and over the average daily production for the coal year to date (1,988,000 net tons) of 3 per cent.

Production of anthracite during the week ended Oct. 26, estimated at 1,714,000 net tons, is exactly the same tonnage as produced during the week preceding, but fell below the corresponding week of 1917 by 339,000 net tons, or 17 per cent. The daily average during the current week is estimated at 286,000 net tons as compared with 334,000 net tons for the coal year to date and as against 332,000 net tons during the same period of 1917. For the period Apr. 1 to date, the total production is estimated at 59,087,000 net tons as compared with 58,789,000 net tons during 1917 or an increase of 0.5 per cent.

Carriers' reports show a decrease a shipments from all districts during the past week with the exception of the district including Cumberland, Piedmont and Somerset, northeast Kentucky and the smokeless fields of West Virginia, southwest Virginia and the district including Iowa, Texas and the Southwest State. Western Pennsylvania, Ohio and the district including Illinois, Indiana and western Kentucky fell behind the most, while the improvement in the various districts mentioned was slight.

Bituminous coal dumped at lake ports during the week ended Oct. 26 is estimated at 1,036,590 net tons, a decrease compared with the week preceding of 8 per cent. and 5 per cent. compared with the weekly average from July 1 to date. Total bituminous coal dumped at lake ports from Apr. 1 to date now amounts to 26,100,000 net tons.

Production of beehive coke in the United States during the week ended Oct. 26 is estimated at 592,000 net tons, an increase compared with the preceding week of 3 per cent., but a decrease of 2 per cent. compared with the corresponding week of 1917. The average production per working day during the current week is estimated at 99,000 net tons as compared with 95,000 net tons during the week of Oct. 19, and 101,000 net tons during the week of Oct. 26, 1917.

The operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production during the week ended Oct. 26 at 352,287 net tons, and the full time operation of their plants at 73.9 per cent. as compared with 75.1 per cent. during the week preceding. Shortage of coke cars caused a loss of full time of 3.8 per cent. and labor shortage of 19.2 per cent. The same operators produced 225,850 net tons of coal.

During the past few weeks, operating conditions in the byproduct industry varied but little, the operators of the country reporting full time operation of their plants at approximately 90 per cent., the limiting factor being reported as necessary repairs to plants. The operators of the country reporting for the week ended Oct. 26, show production of 577,808 net tons, approximately the same tonnage, as produced during the week preceding. Their plants were operated at 90.7 per cent. of their full time and out of a total loss of 9.3 per cent., 6.4 per cent. is attributed to repairs to plants, a slight increase over the preceding week.

Improvement in operating conditions occurred during the week in Kentucky, Massachusetts and New Jersey. In the former two states, it was due to repaired plants and in the latter state to better supply of coal. A decline in production is reported by the operators in Illinois, New York and Pennsylvania, brought about by repairs to plants. Increase in capacity in Pennsylvania during the week is due to the completion of new ovens by the Carnegie Steel Co., at Clairton, Pennsylvania.

BUSINESS OPINIONS

Marshall Field & Co.—Current distribution of dry goods is slightly ahead of the corresponding week of 1917. The volume of road sales for immediate delivery was well in excess of the same period last year. Road sales for future delivery were somewhat heavier. There was a marked falling off in the number of merchants in the market. Collections continue good.

Bradstreet's—Trade has decreased, operations for the future are under leash, and conservation tends to assume a more prominent role. Persistent talk of peace is an unsettling factor; the epidemic of influenza has made for noteworthy inroads on final distribution, has deterred country buyers from visiting the larger centers, and the warmest weather experienced in October for more than a generation has held down buying of fall goods from final purveyors. Despite the evident signs of a debacle among the Central European Powers, manufacturing on governmental account and war preparations in general, except in some shipyards, have not halted, nor is there any disposition to let up on essential activities.

The Iron Age—Munitions contracts were first thought of as most sensitive to the approach of peace, but instead the Shipping Board's action has been the barometer. The steps taken as to shipbuilding in the past week mark the passing of this part of the war program from the wasteful stage, in which haste was the first and last word, toward a basis of economic production. The most efficient yards will be pushed to the utmost, but high-priced operations will not long continue. Some plans for shipyard extensions have been given up; but meanwhile the output of ships will increase. Sentiment in the steel trade as

to coming changes runs all the way from an expectation of depression on the making of peace to a prediction that the need in the transition will be not for Government help in price maintenance but in holding prices down.

Dry Goods Economist—During the week the quotations on raw cotton, both for spot and future delivery, have receded slowly but firmly on the New York Cotton Exchange. Spot cotton dropped 70 points on Monday, 35 points on Tuesday, and 60 points on Wednesday. The highest prices for futures on Wednesday were 29.45 cents for December, and 29.10 cents for January. All other quotations were under 29 cents. Orders for supplies for the new United States Army, that is, for the men now being called to the colors, are being supplemented by calls for additional quantities of various items, presumably with the idea of keeping up the pre-determined reserve. The placing of these orders, which were for a substantial quantity of goods, has had the effect of holding up production of considerable quantities of cotton goods needed for commercial purposes.

American Wool and Cotton Reporter—Acting President Samuel G. Adams of the Boston Wool Trade Association has appointed a committee to draw up some plan to make suggestions to the Government as to the method of handling next year's clip. The larger houses have found that they have been unable to make any reasonable profit, if any, on the basis of 3½ per cent, the amount allowed by the Government, on the wool sold. Some, it is understood, have even operated at a loss. Mixed opinions are heard in regard to the cotton market, price fixing and peace talk. While statements are made that the South is losing money because of the investigation in regard to the price of the commodity, there are others who feel that over-statement has been made and that a reasonable profit will be realized. The opinion is expressed by some that there will be a larger crop than was expected owing to the excellent weather during the latter part of the season.

Atlantic Seaboard

BOSTON

Opinion general that New England requirements for steam coal are now well cared for. Problem to absorb the coal offered. Race between fuel authorities and larger distributors to see who can get to consumers first. More discrimination as to loading is called for, in order to reduce demurrage charges. Recent instances of latter have climbed as high as $3. Buyers alarmed over differential between deliveries by water and those all-rail. Movement via gateways still further reduced. "Free coal" the result of wholesale embargoes. All the railroads comfortably supplied. Increasing disposition on part of large buyers now to accumulate only sparingly. Provincial coal receipts show increase for the present. Anthracite receipts all-rail remain on same level. More cargoes loaded for New England lately than for several weeks. Fuel Administration has issued order to retail coal dealers to furnish broken and pea where egg, stove and chestnut are desired.

Bituminous—There is now a distinct feeling among the trade that requirements throughout this territory for bituminous are now amply provided for. To withdraw more ships would doubtless cause embarrassment, but the fact remains that New England consumers by and large have considerably in excess of four months' supply. Public utilities have been well served, and in every direction there are plants that now have in storage more than regulation are supposed to permit. Arguments are put out to influence consumers to take on coal even more liberally, but even the arrangement reported to have been arranged with Holland for 100,000 tons monthly has failed to make buyers here any more enthusiastic about receiving supplies in any heavier volume.

Even coal with minimum charges, as all-rail delivery from central Pennsylvania, is not the ready sale it was a month ago. The embargoes placed through fuel administration channels have raised havoc with the shipping instructions on file with the mines. And yet new embargoes are being placed from day to day. The idea of the fuel embargo was to insure such better distribution that no plant vitally necessary to the war program should be obliged to shut down from lack of coal while other plants less necessary, were well supplied. Now that every plant the length and breadth of this territory has as much probably as can be used the coming winter, it would seem idle to balk deliveries from mines needing orders to consumers willing to accept coal on the current basis. There will soon be enough deterrent reasons for consumers of their own motion to have shipments suspended. Under present circumstances the coal embargo is obsolescent.

Among the usual distributors in the trade there is much difficulty in placing coal from steamers arriving here. Embargoes have been placed so sweepingly that frequently a shipper has been obliged to parcel out an entire cargo to consignees practically unknown to him, this to the exclusion of regular customers to whom the coal would otherwise have been forwarded on contract.

The whole matter of differentials between water-borne coal and shipments all-rail is to steam-users. All through the season there was a mild sort of pressure among certain of the fuel administration officials to restrict the territory into which all-rail deliveries should be allowed, although more than once the Railroad Administration made authoritative statements that so long as there was no congestion at the New England gateways the matter of car-miles was not important.

Embargoes placed at wholesale have had the effect of forcing something of a tonnage into the open market, particularly from central Pennsylvania, where the embargo has been more often used. Operators who have season contracts with large consumers in this territory find themselves forbidden to make deliveries and in order to place their coal are now being obliged to solicit business from the few consignees who happened to escape the embargo net. There has been a good deal of this coal offering the past ten days. It is a sign of the changing times.

The railroads in New England appear to be comfortably supplied with the exception of the New Haven, which has been repairing and putting into shape several of its larger storage plants. The railroads in this territory have more steam coal on hand than a year ago. One of the smaller roads has nearly five times as much coal as on Nov. 1, 1917.

With all the larger consumers there is an increasing disposition to build up further reserves only very slowly and cautiously. There are many possibilities in the air, and lower marine freights and a reduced price for coal are among them, when it is considered that most of our steam-plants have now on hand coal that will not be used until March or April. Instead of shortage of labor or shortage of cars there may well be next year a shortage of orders.

Among the other receipts of water-borne coal that prove more or less difficult to absorb are certain cargoes of Cape Breton coal that regularly are now seeking a market here. During the spring and summer a certain tonnage of this coal was arranged for through the United States Shipping Board, partly to furnish cargoes for lake-built steamers that were in transit from the St. Lawrence to coastwise ports. Outside that particular quota the coal was then very hard to get, and it is significant that now a consistent effort is made to furnish consignment for cargoes of this that seem to be arriving with more frequency.

For all-rail movement during October complete figures are not yet available. It may be said however that the past week the daily receipts of railroad fuel have averaged only about 95 cars, while early in the month the average was well up to 150 cars. This shows a notable falling off which is equally pronounced with commercial bituminous. For the same recent period the daily average receipts at the five New England gateways were only slightly over 300 cars. The total receipts of bituminous therefore have lately been only about 400 cars per day, as compared with 750 per day during August.

Anthracite—Receipts of domestic sizes continue about on the level of the past month; namely, a daily average of 400 cars at the five gateways. This is only slightly less than the average for August. More hands at the New York loading piers have helped materially in the tonnage dumped into barges for New England consignees, and more cargoes have been loaded the past week than has been the case at any time since Oct. 1. There are still expansive delays at Port Reading, due largely to the lack of facilities there for loading and handling so many bottoms.

There continues to be a notable shortage of stove and chestnut, practically every retail consignee being obliged to accept a proportion of broken and pea. The result is a pronounced surplus of these sizes, and in certain communities the local fuel committee have been broad-minded and courageous enough to insist that householders accept what they can burn in their heaters and ranges rather than what they prefer. Finally, the Boston Fuel administration followed suit, and dealers have been ordered to furnish broken and pea instead of egg, stove and chestnut.

NEW YORK

Wage increase creates a better feeling in mining regions and it is believed many workers will return. Coal not moving as freely as desired but warm weather eases consumption. Local dumpings show an improvement. Buckwheat and the smaller sizes plentiful, and consumers who can do so are urged to use buckwheat instead of the larger coals. Bituminous situation easy.

Anthracite—The increase in wages granted the mine workers in the anthracite regions has created a much better feeling, and will go a long way toward inducing many of the former employees who left for other industries because of higher wages and better conditions to return to their former employment. Operators are estimating that several thousand men and boys will be back in their old jobs.

Locally the situation, so far as receipts go, continues to be acute. Coal has not been moving as freely as the trade would wish, but there is no serious complaint inasmuch as weather conditions have not been conducive to heavy consumption. Unseasonable temperatures during the latter part of October eased up coal burning considerably, and this is greatly responsible for the present condition which is good considering that production was further cut by the influenza epidemic.

Receipts here are reflected in the dumpings for the week ended Nov. 1, which show an increase over the previous week, 6425 cars having been dumped as against 5597 the previous week. For the month of October the dumpings were 26,615 cars, as compared with 27,944 cars in September, and 32,494 cars in August, certainly not an encouraging sign as cold weather approaches. However, as dealers point out, the fact that nearly every consumer has more or less coal on hand to tide them over for at least a few weeks, would indicate that conditions are better than they have been in previous years.

With a scarcity of the larger domestic coals, there is an abundance of the small sizes available, and some shippers continue to shave prices in order to move rice and the smaller coals. Those consumers who can do so, and those who can change their grates to burn this class of fuel, are being advised to make the changes because as it is pointed out by the State Fuel Administration they can secure a sufficient supply. The Anthracite Committee has sent out circulars stating that advices have been received that there is no restriction at the present time on the amount of anthracite coal below buckwheat No. 1 that a manufacturer may receive. The State Fuel Administrators have also been authorized to give country clubs the necessary permits to receive and burn bituminous or steam anthracite whenever, in their opinion, there is a surplus of such fuel for that purpose.

Some anthracite dealers are advising their consumers that it is possible for them to burn the small sizes in their household furnace providing they make a bed of ashes.

Current quotations, per gross ton, f.o.b. tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$6.75	$7.50	Buck	$5.10	$5.90
Egg	6.65	7.40	Rice	4 65	5.10
Stove	6.90	7 65	Barley	4 15	4.30
Chestnut	7.00	7.75	Boiler	4.60	
Pea	5.50	6.25			

Bituminous—The local situation is favorable. There is plenty of commercial coal to go around, with some to spare, as a result of the unseasonable temperatures that existed a week ago. In fact, stocks with some shippers have been so large within the past ten days that there were fears that prices would have to be cut in order to move the coal. This, however, was not necessary as there was another serious cut in production due to the influenza epidemic.

Some shippers look for a further reduction in production now that the railroads have discontinued giving box cars to operators of wagon mines, the order having gone forth that these cars are needed in the West for the shipping of grain. Wagon mine owners received an allowance of 75c. per ton for loading these cars, which they now lose. What, if any, effect this will have upon production is a matter of conjecture, although some shippers look for a slight reduction in production figures.

The order of the Fuel Administration permitting the local traction and lighting companies to accumulate 100,000 tons of bituminous coal each, in order that there may be no interruption of service this winter, may be the means of cleaning up considerable of the surplus coal here. This tonnage represents approximately 60 days' supply for each of the traction companies, and the accumulation has been authorized where there is risk of interruption of transportation during the winter.

While there is an accumulation of ordinary grades in the market there is a good demand for the better grades, which are scarce, being taken up by regular customers and those who need them for their particular business. Conditions in the bunkering market are not as favorable. Production of the coals necessary for this class of trade have been greatly reduced.

Water shipments to New England and towns along the Long Island Sound have not improved greatly. Efforts are being made to hurry coal forward to these points before the approach of winter weather and the attending transportation difficulties.

Current quotations, based on Government prices at the mines, net ton f.o.b., tidewater, at the lower ports, are as follows:

	Mine Gross	F.o.b. N. Y. Gross
Central Pennsylvania:		
Mine-Run, prepared or slack	$3.30	$5.45
Upper Potomac, Cumberland, and Piedmont Fields:		
Run-of Mine	3.08	5.23
Prepared	3.36	5.51
Slack	2.80	4.95

Quotations at the upper ports are 5c. higher.

PHILADELPHIA

Anthracite wage increase causes slight stir. Consumers anxious as to their prices. Shipments meager. Companies assure trade of full allotments. Pea plentiful. Stove and nut grow scarcer. Steam coals all slow but No. 1 buckwheat. Bituminous continues plentiful. Good stocks ahead. Market approaching quality basis?

Anthracite—The decision of Dr. Garfield to allow the anthracite miners a wage increase averaging $1 a day was heralded so far in advance as to cause no particular surprise to the trade. For several days prior thereto it was known that the leading anthracite representatives were in Washington, and it was understood they were figuring out the details of the new mines price for the coal. It was intimated very strongly that the increased wage schedule could be put in effect without a consequent increase in the wholesale price.

So far as demand for coal is concerned, the almost unprecedented mild weather has avoided what would otherwise have been an uncomfortable situation. Practically no coal to speak of has come to the city during the past two weeks and the dealers are far from showing the same patience as the public. No fires have been needed and the consumers have been less insistent than in cooler weather.

After interviewing representatives of several of the larger shippers we are strong in the belief that this territory is to be further neglected. Coal is moving west and to tide, particularly the latter, and there are no signs of it being diverted to this market for the present. The shippers show little disposition to advise their customers just what they may expect. The reason for this, we are told, is that so many times their plans have been made only to be upset by some preferential order of the fuel authorities. We are, however, much inclined to believe that the small shipper does not consider himself under the control of the Fuel Administrator to the same extent as the large companies. As proof of this we know of dealers who bought no coal from shippers during the basic year of 1916-17 but who are now receiving coal from that source. No large tonnages are involved, but the exceptions are causing the trade to lose faith in the whole scheme. Another instance that we know is irregular is the offering of prepared sizes as an inducement to sell the slowly moving culm. Such cases may be rare but the transactions invariably leak out.

The companies are advising their trade that all their allotments will be shipped and there is every reason to believe they will be. The regular, steady consignments so much desired will not be possible under the present method of starting heavy shipments and then suddenly diverting to another market. The smaller dealer fears coal will arrive in larger quantities than he can unload without demurrage charges. All dealers claim it is almost impossible to secure help to trim coal and therefore they will be unable to fill their yards to their capacity if it does come in bulk.

Pea coal is by all odds the most plentiful of the family sizes and many dealers are using every effort to persuade buyers of chestnut coal to use it. Egg is not so scarce in the city proper, but in the suburbs where Philadelphia's portion is chiefly consumed, it is eagerly sought. Stove and chestnut seem to grow scarcer every day and many yards have had no stocks of it for weeks.

That the smaller steam sizes drag is shown by the new ruling of the anthracite committee of the United States Fuel Administration. There is now no restriction on the tonnage of anthracite in sizes below No. 1 buckwheat that a manufacturer or a florist may receive. This is particularly pleasing to the latter, who because of having been restricted to 50 per cent. of their fuel requirements were in despair. Many of the smaller growers anticipating the winter's coal troubles quit the business last spring and summer. As it stands now the sizes of steam coal smaller than No. 1 are becoming so common that some larger users with big stocks ahead are reaching the position where they want to name the kind of coal rather than merely take in a certain size which had become the custom since the war conditions arose.

Some welcome news was conveyed to the dealers this week when the railroad companies announced they would make refund for coal lost and stolen during the so-called coal famine last winter, when crowds mobbed loaded cars of coal and carried the fuel away. Dealers have been notified to call in person and sign vouchers releasing the carrying companies from all claims in excess of those already presented.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.45
Egg	4.80	6.15	Rice	2.90	3.80
Stove	5.05	6.40	Boiler	2.70	3.70
Nut	5.15	6.50	Barley	2.40	3.30
Pea	3.75	5.00	Culm	1.25	2.15

Bituminous—Soft coal continues in abundance, with almost every one being fairly well supplied with good shipments. Of course, the tonnage coming into the city has shown some slight decrease due to the shortage of man power in the regions on account of the influenza epidemic reaching its height there. All restrictions as to storing seem to be down, and there is a general feeling that the coal question has been solved this winter. Certainly there never was a greater tonnage of coal above ground in this district. Even small concerns who are only accustomed to run from one car to the next have from 30 to 60 days' supply on hand.

BALTIMORE

Bituminous conditions here remain tight in the face of a constantly growing demand. Jobbers puzzled as to their status under new rule. Hard coal supply far below needs. Substitutes urged are not available.

Bituminous—With the mine forces and railroads slowly recuperating from the effects of the epidemic of influenza, there is still a movement recorded considerably below the recent normal of coal handling. The result here is that conditions for soft coal remain very tight, and this is the more marked as additional consuming concerns come into the field for a resumption of coal shipments as their reserve supplies, at one time from 60 to 120 days ahead, have dwindled to the allotment allowed by the government for non-essential and essential industries.

During the past week the local fuel administrator has sent quite a number of requests for diversion to the district representative to care for this business, not enough coal having arrived here to the account of the administrator to care for the distribution. A pretty fair line of coal is now coming through, when the fact that the government is using the best grades for strictly preferential business, is considered. Action against some mines accused of sending dirty coal through has apparently had some effect on the situation, and little real complaint is heard among consumers here now as to the grade of coal supplied.

The jobbing trade continues puzzled about the effect of the order which enables mines to bill consumers direct, when they so elect, on coal requisitioned by the fuel administrators. Some believe that only the largest mines have facilities for handling such business direct and that jobbers as a whole will not be seriously injured, while others believe that the practice will finally hit the line of business hard. The Maryland Jobbers' Association discussed the subject, and was told of some concrete examples where purchasing agents were in danger of losing long established consuming connections, and it is understood the subject will be taken up with the Fuel Administration in Washington.

Anthracite—The hard coal supply here remains far below needs. For the first six months of the coal year it is announced that a total of 543,696 tons was received by Maryland on an allotment of slightly more than one million tons; of which Baltimore city and suburbs received 365,654 tons on an allotment of slightly more than 700,000 tons. The shipment covered both steam and coal for specialized war industries and public service corporations. Under the two-third distribution plan, however, many homes have as much coal as they can burn until January or February next, while thousands have no coal at all.

Lake Markets

PITTSBURGH

Production down 40 per cent. altogether. Next change will be improvement. Weakness in some Ohio markets. Pittsburgh coal firm.

R. W. Gardiner, production manager for the Pittsburgh district, estimates that coal production at the moment in the district is running 40 per cent. below the maximum rate which was attained just before the epidemic of influenza started. This does not mean that miners have the disease in any such proportion, as some are at home on account of sickness in the family and some have absented themselves because inoculation against the disease reduced their enthusiasm for work. Furthermore, there has been some car shortage due to railroad employees being affected by the disease. For a time the situation as to shipments east on the Pennsylvania was very bad, there being scarcely any movement, in fact. Mr. Gardiner feels that the authorities have now got the situation well in hand, as to inoculation and segregation, and that the effects of the epidemic will now wane.

Lake shipments are being maintained about as well as was expected when the diversion of 200 cars weekly to domestic trade in addition to previous movement was ordered, that being before influenza threatened. In the week ended Oct. 19 more than 300,000 tons was moved, and it is probable that the average will be about 300,000 tons a week to the end of the season. Shipments will cease within a fortnight or so.

Opening of the Black Rock gateway has allowed considerable Ohio No. 8 to move into Canada by rail and has to an extent relieved the situation there, as to there being a surplus of coal over the demand of the markets in the zone; and with the curtailment in production generally there is less surplus in Ohio districts than there was. It remains the fact, however, that retail dealers and domestic consumers are better supplied at this time than was expected would prove the case, and the coal situation as a whole is relatively easy. As usual, exception must be made of the byproduct situation, as it is only with difficulty that the byproduct plants are supplied, and even then they do not always receive the kind of coal they require for the most efficient operation, while they receive little if any coal to place in storage.

TORONTO

Transportation conditions show improvement. Local deliveries slow owing to the epidemic. Large numbers still destitute of fuel. Remedial measures by provincial fuel administration.

Transportation conditions have latterly shown some improvement, and coal shipments from the mines are coming forward promptly. The local situation, however, is still quite serious. The work of supplying some 12,000 families reported as being completely destitute of fuel goes forward, but slowly, as a large percentage of the employees of the coal companies are laid off owing to the prevailing epidemic and deliveries are greatly retarded. The situation is particularly bad in the suburbs and outlying districts. R. Home Smith, Ontario Fuel Administrator, has warned coal dealers that matters have taken a critical turn, owing to the presence of influenza in the mining districts, which has so curtailed production as to threaten the season's supply. Dealers are urged to lay in a supply of bituminous, which is at present plentiful, and to advise the purchase of buckwheat and small sizes of an-

thracite to mix with ordinary sizes. All anthracite stocked in public buildings has been placed at the disposal of the local fuel commissioners, and made available for domestic consumption.

BUFFALO

Bituminous more plentiful. Consumers not buying freely. Anthracite not increasing. Lake shipments good.

Bituminous—Supply is ahead of the demand and there is quite some unsold coal on the market. Jobbers report that they are now receiving proffers of coal from the mines. Slack is especially plentiful. This state of things cannot last long. The influenza has cut down production materially, and there would surely be a shortage but for the closing of the lakes at the end of this month, which always makes the eastern supply easier. It will be some time before these contending influences can be sized up, and in the meantime it looks as if consumers were going out of the market too soon.

In spite of regulation, bituminous prices must now be reported as weak, but still at $4.65 for thin vein Allegheny Valley, $4.45 for Pittsburgh lump, $4.20 for Pittsburgh mine run and slack, $5.65 for smithing and smokeless, $5.60 to $6.10 for cannel, all per net ton f.o.b. Buffalo.

There is an effort to get a return to this market of the Ohio No. 8 after the lakes close, as it was cut off in order to supply that trade.

Anthracite—The demand keeps up, but the supply is light so far as the local trade goes, and it is likely to be so for at least another month. Some towns are adopting the plan of delivering one ton to a customer till all have some, but the retailers do not like the idea on account of the extra work.

It does not look as if the amount of coal in cellars was less than usual, but it is not well distributed. Some retailers have paid little attention to the rules and have delivered large amounts to friends and those who were most persistent in demanding coal. It is of course to their interest to do this. Everybody hopes that the shippers are right when they declare that there will be coal enough. They agree that it will be short of the demand practically all winter, for the consumers want their full supply now and will not relax their demands till they get it.

Shipments by lake continue liberal. There were no storms of consequence in October to hold up the fleet, so the loading went on unabated. Tonnage is plenty. The amount reported for the week was 140,300 net tons, of which 83,400 tons cleared for Duluth or Superior, consignee's option, 25,100 tons for Chicago, 13,800 tons for Milwaukee, 6600 tons for Ashland, 5500 tons for Fort William, 3200 tons for Hancock, 2700 tons for Racine.

The rate to Racine has advanced 25c., and Hancock, 27c., the list being $1.25 to Racine, 75c. to Hancock, 60 to 65c. to Chicago, 55c. to Milwaukee and 48c. to Duluth, Ashland and Fort William, per net ton, f. o. b. vessel.

CLEVELAND

Production in eastern and southern Ohio has been severely cut by the influenza epidemic, but on account of the decreased demand for bituminous for the lake trade this loss is scarcely being felt. Bituminous supply for the retail trade finally has become equal to the demand. Unexpectedly, the lake trade will come to an end 15 to 20 days before the date fixed, but the Northwest will receive its full quota in spite of this fact.

Bituminous—Production losses of 40 to 50 per cent. suffered by southern and eastern Ohio mines because of influenza are common reports just now. As operators were believing that the worst was over the epidemic broke out with renewed violence, and because of the scarcity of physicians and nurses in the small mining communities the death rate has been alarmingly large. Railroad crews have been affected even worse than the mine workers, but even so car supply has been exceeding requirements. For the first time in months retail dealers report receipts of bituminous equal to the demand. Also for the first time in months, operators are offering tonnages to retail dealers. Domestic consumers, however, are well coaled and dealers are not swift to seize at operators' proffers.

With shipments of slack and run-of-mine cut off from the Northwest, the supply for industrial consumers has increased appreciably. The demand for slack for more than a year has been greater than the supply, and all the slack turned on the market is being snapped up eagerly. Industrial and domestic receipts are coming in at about the same gait as for the past two weeks, the lost production due to influenza being taken up by the slackening lake trade.

Anthracite—Advice of the Ohio fuel administration that No. 1 buckwheat—which is practically all that has been coming here for some time—can be profitably burned when mixed with 70 per cent. stove and egg sizes is being accepted with reservations. All that is lacking is the remaining 70 per cent., dealers point out. Receipts of anthracite continue at a small fraction of the demands, and arrival of 100 cars a week is considered big.

Lake Trade—Diversion of vessel tonnage by the British has caused congestion at North Atlantic grain elevators. Consequently, elevators at Buffalo are choked, and the plans to divert lake carriers from ore to grain for all of November and half of December have been abandoned. As a result, the lake season will come to a close two or three weeks earlier than expected, and practically no coal will be floated after Dec. 1, it is now believed. Last December over 660,000 tons of bituminous were loaded for the Northwest. October's shipments, however, in the final analysis will be found about 1,000,000 tons ahead of the schedule, which called for 3,500,000 tons, and 2,400,000 tons in November, as planned, will just about see the Northwest supplied its 28,000,000 tons. The heavy movement in the first three weeks of October is all that has saved the Northwest, in view of the unexpected turn of events. With no grain to bring down there will be no need of coal ballast for the planned upbound trips. Upper lake docks, however, are so heavily loaded down the little coal that now is coming forward to Lake Erie ports is not consigned. Where bituminous loading at the lower lake docks averaged about 1,100,000 tons a week for the first three weeks of October, it now is at scarcely more than 700,000 tons. Modification of the zone lines, giving Ohio mines a larger outlet for the coal capacity that has been going up the lakes, is expected to take up the slack that will result when influenza wanes and full time production is resumed.

DETROIT

Steam coal is attracting less interest. Domestic buyers seem inclined to delay, hoping to get anthracite. Lake trade maintains good volume.

Bituminous—Although good steam coal is not overplentiful, the consumers seem less eager to buy than they were a few weeks ago. The fact that a number of the large manufacturing plants have fairly large reserves, while many of the industrial plants of lesser magnitude have no place to put more than a carload or so, is the explanation of the quieter state of the local market, according to jobbers. The insufficiency of storage accommodations at many of the plants also is preventing numerous consumers of steam coal from taking full advantage of the Federal Fuel Administration's recent relaxation of the restrictions on the size of reserves.

Jobbers say also that the consumers of steam coal, to assure a sufficient supply of stock, have been taking more or less coal of poor quality, which they desire to use before adding to their supply. The retail dealers are described as having found themselves confronting a similar problem, created by stocks of mine-run and coal from Illinois mines, which restrict their buying of the prepared sizes of better grades of coal coming into the market from Ohio and West Virginia. Domestic consumers, the jobbers say, are asking for the coal that dealers are in an unfavorable position to supply and are objecting to receiving the coal on hand.

Anthracite—Anthracite has been moving into the Detroit market more freely during the month and receipts are estimated at around 90,000 tons, part of which must be charged off on deliveries to be made later in the year. By crowding the early shipments it was planned to make possible distribution of part of their winter allotment to a greater number of families before weather conditions arise that may interfere with the program. The increase in movement threw a heavy burden on retailers. With labor hard to get and working forces reduced by the epidemic of influenza, delivery from cars to customers was not in all cases possible, and some of the dealers were obliged to unload cars in their yards, incurring the expense of handling the same stock several times.

COLUMBUS

A slack in the demand for both mine-run and screenings characterizes the Ohio trade. Restrictions on shipping mine-run into Michigan have produced an oversupply. Mine-run from the Hocking field cannot be shipped to the lakes. There is a good demand for lump and lake tonnage.

The feature of the coal trade in Ohio during the past week was the large amount of mine-run on the market and the efforts required on the part of sales agents to sell it. This is so different from the conditions that have prevailed for the past year or more as to be worthy of special notice. With mine-run kept out of the hands of Michigan steam users and further restrictions against shipping it to the lakes, the supply of that grade became large. Steps were taken at once to get the railroads to take mine-run in preference to using Indiana coal, as was ordered, and after several days the Fuel Administration secured the modification. That helped to relieve the situation to a certain extent. Operators had about decided that they would have to curtail production unless some relief was afforded. Steam users in Ohio are generally stocked up to the limit and in many cases have fuel supplies for three months in the future.

The lake trade is still active and a large tonnage is still moving to the Northwest. Reports indicate that the requisition for that section will be filled unless something unforeseen occurs. There is sufficient mine-run and screenings in the upper lake region, which has resulted in the prohibitions against shipping those grades from Ohio.

The retail trade is rather quiet because of the continued warm weather. Dealers have large stocks ahead and most of them have all available storage space filled. Dealers have a good supply of mine-run and are not accepting any more. They are still in the market for lump when obtainable. Pocahontas is out of the market completely. The Ohio dealers are depending largely on Ohio mined coal for their supply. Some West Virginia grades are being received. Retail prices are firm at former levels.

CINCINNATI

With demand good in all departments, the epidemic is the most serious factor in the supply. Little improvement is reported from mining districts.

Somewhat cooler weather prevailing during the past week tended to stimulate consumption of coal for heating purposes, and to that extent to improve the demand, which, however, has remained about normal, with an excellent supply, especially of steam coal. Domestic coals are also available in good supply, and several of the larger retail concerns are making vigorous sales efforts, by way of advertising, solicitation and otherwise, a condition which it was hardly anticipated would prevail during this season. Good receipts of rail and river coal, enabling these companies to accumulate large yard supplies, gave them the opportunity to do some aggressive sales work, and the opportunity was not overlooked.

Conditions at the mines are threatening seriously to interrupt the forwarding of adequate supplies of fuel, however, as the influenza epidemic, which is at its height in the Ohio, West Virginia and Kentucky fields within overnight journeys from this point, has reduced working forces badly. Should cold weather, which is daily expected by the weather office, come suddenly, bringing its usual large demand for fuel, receipts might prove inadequate. It is hoped that the epidemic is nearing its end, but just now the daily record of new cases and of deaths does not indicate any slackening of the power of the disease.

LOUISVILLE

General demand for coal draggy with possible exception of better grades of eastern Kentucky lump. Retailers loading up first real stocks of a long time. All grades of steam dull.

Mild October weather, coupled with the fact that domestic consumers as well as steam consumers are well stocked, has resulted in all grades of Western Kentucky coal being draggy, while Eastern Kentucky domestic coal is the only grade that is showing a real demand. It is claimed that Eastern Kentucky lump stands a good chance of being in demand throughout the entire season, owing to the small supplies that have been received to date, and the fact that no Virginia or Pittsburgh coal to speak of has been coming by rail or water. However, steam consumers using the better grades of Eastern Kentucky are apparently well stocked and are not buying liberally.

Western Kentucky domestic and steam coal has been sold freely on the market during the past few days, as several of the Western Kentucky operators were unable to make full delivery on Southern contracts, owing to influenza which closed down many industrial plants and resulted in a halt being called on the Western Ken-

tucky shippers. The result was that these shippers shoved as much coal into Louisville as the market could take care of. The steam grades were not wanted, while the domestic demand was chiefly from the retailers, who would have been willing to take considerably more coal if they could just get the labor to unload from cars.

There has been a considerably larger supply of Hazard coal coming on the local market within the past two weeks or so, and many consumers who had been objecting to taking deliveries of lower grades of western Kentucky accepted this coal.

Jobbers have been handling a little Indiana coal into Northern Indiana points, and have been fairly active in a small way in handling Kentucky coal in Louisville and out through the state, but as a whole the jobbing trade has been dull for the past two or three weeks in so far as steam and western Kentucky lump is concerned. Retailers are in the same fix, and being unable to sell have gone ahead and accumulated from a week to two weeks or better supplies of coal on the local yards, this being by far the best supply of domestic coal that has been on hand in the city at one time in a year or eighteen months.

Production has been very low as a result of influenza, which is showing much improvement, and which appears to be virtually checked in many localities. Many of the mines are beginning to get out something like normal production again. Eastern Kentucky mines expect to continue making deliveries to the lake region for three weeks if weather conditions permit, while southeastern Kentucky is still shipping south, and the Elkhorn district to the gas and byproduct plants. The short production caused by the epidemic has not been appreciably felt, and it is hardly believed that it will be felt to any great extent due to the fact that the country was well stocked up, and there was not much place to put fuel when the epidemic interfered.

BIRMINGHAM

With influenza on the wane coal production again improving. Steam market rather inactive. Domestic strong. Car supply adequate to requirements.

With the influenza epidemic, which has so seriously retarded coal production in Alabama for the past two weeks, rapidly losing its grip, the output is now showing a gradual upward trend. Sickness among mine workers at some camps completely paralyzed operations for several days, and caused more or less loss of tonnage at every mine in the state. The output for the week ending Oct. 19, was 323,310 net tons, the lowest since the Government has been tabulating production.

Despite the fact that there has been such a sharp decline in coal produced the steam market has not been stimulated to any noticeable extent. Buyers are manifesting a passive attitude, and new business and bookings already in hand are about equal to the available tonnage. Shippers have instructions to fill railroad orders 100 per cent. before supplying other consumers.

The domestic trade is very active and the shortage in supply is being felt by both consumers and dealers. Stocks on yards are low and retailers have much unfinished business on their books. The State Fuel Administrator has restricted delivery by dealers to one ton to each family at any one time, effective Nov. 1.

The Fuel Administration has granted an increase in the price of coal mined by the Warrior-Pratt Coal Co., fixing a figure of $2.25 for mine-run, $2.50 for prepared sizes, and $2 for slack and screenings. The West Helena Coal Co. is also allowed an advance, the new prices being $3 for mine-run; $3.30 for prepared and $2.65 for slack and screenings. To the above figures is to be added 45c. per ton.

Cars are now plentiful in this district and no complaints are reported on service being afforded.

Coke

CONNELLSVILLE

Curtailment in production less than might have been expected. Price expectations in event of hostilities ceasing.

Production of coke and of byproduct coal in the Connellsville region, while considerably curtailed by the epidemic of influenza, is considered relatively satisfactory in the circumstances.

While supplies of coke and byproduct coal are curtailed, there has been no particular shortage of coke at blast furnaces such as would in itself interfere with pig iron production. Indeed, a number of blast furnaces have been in more danger of banking on account of the influenza epidemic decreasing their working forces, than from any shortage of coke.

The imminence of a cessation of hostilities has brought to the front consideration of market conditions in such event. The iron and steel trade has hitherto regarded all Government prices as of virtually the same order, although iron and steel prices are fixed by the War Industries Board by agreement with the producers, while coal and coke prices are fixed by the Fuel Administration, under authority of the Lever act. For the transitory period the case is different. If it became desirable to sustain prices in the period from war time to peace time conditions, an agreement with producers as to minimum prices (fixed prices thus far having been a maximum, not minimum) might encounter legal difficulties. Coke, accordingly, takes a place by itself. The Fuel Administration's authority extends at least to the declaration of peace by Presidential proclamation, which doubtless will occur long after the cessation of actual hostilities has made business start seeking a peace basis, while furthermore a broad construction of the Lever act would seem to indicate that the authority granted is to fix prices either way, maximum or minimum, it being simply a detail that the Fuel Administration found that what was needed for the good of the country, being at war, was a maximum price for coke and not a minimum. The market remains quotable at the set limits: Furnace: $6; foundry, 72-hour selected, $7; crushed, over ¾-in., $7.30; clean screenings, over ½-in., $5.50, per net ton at ovens.

The "Courier" reports coke production in the Connellsville and Lower Connellsville region in the week ended Oct. 26 at 302,394 tons, a decrease of 11,651 tons, and raw coal shipped 234,517 tons, a decrease of 11,561 tons.

Middle Western

GENERAL REVIEW

No change over recent weeks. Car shortage and influenza decrease production. Only thing that will put life into Middle West market is a radical readjustment of zones.

The market is still weak, and this is rather remarkable when one considers that the production figures have taken a heavy drop, and at the same time an outside factor has entered the market and bought a large quantity of coal. We are referring to some of the railroads who have mines of their own, ample in size to take care of all the wants of their railroad owners. These mines, however, have been down on account of the influenza, and as a direct result their owners have been forced into the open market to purchase their coal. It is worth stating in passing, that in most cases these railroads have been able to purchase as much coal as they desire, at a figure considerably below the prices set by the Government.

The car question is again coming to the fore. The order some time back, taking coal-carrying equipment from the Middle West fields and sending it to eastern mines, is beginning to be felt by the operators, especially in the southern Illinois field, and in some districts of Indiana. This car shortage, while it is not serious at the present time, will nevertheless decrease the production figures for the week to a noticeable extent

The prevailing question among the operators is—"What will the situation be when operating conditions come back to normal, when it has already been demonstrated that the market for Illinois and Indiana coals cannot absorb even a greatly decreased tonnage?" The only answer to this question is a radical readjustment of the zones, which will give producing territories affected a larger and more extensive market for their productions.

The recent changes made in Zone D, for the benefit of the Indiana operators, have not proved as beneficial as hoped for, as there has been practically no change in the market on Indiana coals. There is a possibility however, that freight rates will be published for coal from mines in Indiana to points in Michigan hitherto not reached, except by expensive local rates. If these proposed rates are published, it will open up practically a new territory for Indiana, and ought to strengthen the present weak market in that district to a noticeable degree.

CHICAGO

Plenty of steam and domestic coal in Chicago. Little anthracite being received.

Coal continues to be plentiful in Chicago, both steam and domestic. We understand that today there are approximately three hundred cars of coal in the central district of Illinois, that are standing on the track, on which no disposition has been received. This is a decidedly significant thing, especially in view of the fact that both the State Fuel Administration and the District Representative for the Fuel Administration are doing everything they can to move this coal. There are an increasing number of fires reported in the various large storage piles throughout the city, and this, no doubt, has a tendency to hinder further purchases on the part of the large consumers.

The domestic situation is practically the same as the steam situation, with plenty of coal of all kinds being offered, and orders being canceled rather than placed.

There is little hope extended to the trade, so far as anthracite is concerned, and the parties who are handling this question for the Fuel Administration are still continuing to create considerable criticism.

ST. LOUIS

A lagging market, with no demand for either steam or domestic, and a surplus of all coals offered. Country business weak and prices unsettled. Mild weather continues and future is not promising. Cars plentiful and transportation good.

The local domestic demand at the present time is nil. The mild weather has even eliminated the usual buying of Standard coal among the poorer classes. This, of course, will come with colder weather. Steam users are buying just as little as possible, knowing that this attitude will force lower prices; and it has already done so in the case of Standard coal. Standard screenings are down to $1.50, 2-in. lump to $2.15, with the other sizes breaking below the Government maximum. In the Standard districts the mines are working only to the extent that orders are furnished. There is no car shortage. Conditions in general throughout the Standard field are satisfactory, or would be if there were orders. Labor seems to be better and car supply and transportation satisfactory.

In the Mt. Olive field the mines are working steadily, but the operators are having a hard time to dispose of the tonnage. There is a surplus in this field, as well as in others. Conditions are much better than in the Standard field, as this coal moves to better markets, and under better rates and conditions.

In the Carterville and Duquoin fields the car supply has improved to a great extent recently, and conditions in a general way are satisfactory, except that at some mines domestic orders are being caught up with. Throughout all southern Illinois the question of labor at some mines has been serious on account of the influenza epidemic.

The railroad tonnage throughout the entire district continues heavy. As a matter of fact, in the Standard and Mt. Olive fields if it were not for the railroad tonnage the general average of working days at the mines on commercial coal would be about 1½ days per week.

The domestic tonnage, however, in the Carterville and Duquoin fields for the present could take all the working time, but these orders will be caught up with in the course of ten days or two weeks' time and then the railroad tonnage would have to come in in order to keep the property running.

A strenuous effort has been made on the part of the Illinois operators and dealers in the State of Missouri and states west of the river to have the Fuel Administration release the present restrictions on zones for Illinois coals.

No outside coals are coming into St. Louis. There are no changes in the retail prices, and the wholesale prices are with the exception as noted above the same as last week, which are:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.75	$2.55@2.75	$2.40@2.70

CAST-IRON PIPE—The following are prices per net ton for carload lots:

	New York Current	New York One Month Ago	New York One Year Ago	Chicago	St. Louis	San Francisco
4 in.	$70.70	$64.35	$68.50	$69.80	$68.00	$80.50
6 in. and over.	67.70	61.35	65.50	66.80	65.00	77.50

Gas pipe and 16-ft. lengths are $1 per ton extra.

STEEL RAILS—The following quotations are per ton f.o.b. Pittsburgh and Chicago for carload or larger lots. For less than carload lots 5c. per 100 lb. is charged extra:

	Pittsburgh Current	Pittsburgh One Year Ago	Chicago Current	Chicago One Year Ago
Standard Bessemer rails	$57.00	$38.00	$67.00	$38.00
Standard openhearth rails	55.00	40.00	65.00	40.00
Light rails, 8 to 10 lb.	*3.135 (100 lb.)	83.00	*3.135 (100 lb.)	68.00
Light rails, 12 to 14 lb.	*3.09 (100 lb.)	82.00	*3.09 (100 lb.)	67.00
Light rails, 25 to 45 lb.	*3.00 (100 lb.)	75.00	*3.00 (100 lb.)	65.00

* Government price per 100 lb.

OLD MATERIAL—The prices following are per gross ton paid to dealers and producers in New York. In Chicago and St. Louis the quotations are per net ton and cover delivery at the buyer's works, including freight transfer charges:

	New York	Chicago	St. Louis
No. 1 railroad wrought	$30.90	$30.00	$33.00
Stove plate	26.10	25.00	25.50
No. 1 machinery cast	34.00	29.00	20.50
Machine shop turnings	16.85	16.50	18.50
Cast borings	16.85	16.50	18.50
Railroad malleable cast	31.10	29.00	32.50

COAL BIT STEEL—Warehouse price per pound is as follows:

New York	Cincinnati	Birmingham	St. Louis	Denver
$0.12	$0.16½	$0.18	$0.19	$0.18½

DRILL STEEL—Warehouse price per pound:

	New York	St. Louis	Birmingham
Solid	16c	16c.	15c.
Hollow	24c.	...	...

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh; basing card of Nov. 6, 1917, for steel pipe and for iron pipe:

BUTT WELD

Steel Inches	Steel Black	Steel Galvanized	Iron Inches	Iron Black	Iron Galvanized
⅛, ¼ and ⅜	44%	17%	¾ to 1½	33%	17%
½	48%	33½%			
¾ to 3	51%	37½%			

LAP WELD

2	44%	31½%	2	26%	12%
2½ to 6	47%	34½%	2½ to 4	28%	15%
			4½ to 6	28%	15%

BUTT WELD, EXTRA STRONG PLAIN ENDS

⅛, ¼ and ⅜	40%	22½%	¾ to 1½	33%	18%
½	45%	36½%			
¾ to 1½	49%	36½%			

LAP WELD, EXTRA STRONG PLAIN ENDS

2	42%	30½%	2	27%	14%
2½ to 4	45%	33½%	2½ to 4	29%	17%
4½ to 6	44%	32½%	4½ to 6	28%	16%

From warehouses at the places named the following discounts hold for steel pipe:

	Black New York	Black Chicago	Black St. Louis
⅜ to 3 in. butt welded	40%	43%	37%
3½ to 6 in. lap welded	36%	39%	33%
	Galvanized New York	**Galvanized Chicago**	**Galvanized St. Louis**
⅜ to 3 in. butt welded	28%	28%	22%
3½ to 6 in. butt welded	25	25%	19%

Malleable fittings. Class B and C, from New York stock sell at list + 15%. Cast iron, standard sizes, 5% off.

SHOP SUPPLIES

NUTS—From warehouse at the places named, on fair sized orders, the following amount is deducted from list:

	New York Current	New York One Year Ago	Cleveland Current	Cleveland One Year Ago	Chicago Current	Chicago One Year Ago
Hot pressed square	$2.50*	List	$1.25	$1.65	$0.98	$2.00
Hot pressed hexagon	2.50*	List	1.05	1.50	.78	2.00
Cold punched square	2.50*	List	.75	1.25	1.00	1.50
Cold punched hexagon	2.50*	List	75	1.25	1.00	1.50

* List plus.

Semi-finished nuts sell at the following discounts from list price:

	Current	One Year Ago
New York	40%	50%
Chicago	50%	50%
Cleveland	50 + 10%	50%

MACHINE BOLTS—Warehouse discounts in the following cities:

	New York	Cleveland	Chicago
⅜ by 4 in. and smaller	30%	40 + 10%	37%
Larger and longer up to 1 in. by 30 in.	15%	20 + 5%	25—5%

WASHERS—From warehouses at the places named the following amount is deducted from list price:

For wrought-iron washers:
New York....$2.50 Cleveland.... List Chicago....$2.50

For cast-iron washers the base price per 100 lb. is as follows:
New York....$5.00 Cleveland....$4.25 Chicago....$4.50

RIVETS—The following quotations are allowed for fair sized orders from warehouse:

	New York	Cleveland	Chicago
Steel ½ and smaller	30%	45—5%	40%
Tinned	30%	45—5%	40%

Button heads, ⅜, ½, 1 in. diameter by 2 in. to 5 in. sell as follows per 100 lb.:
New York...$5.65 Cleveland...$5.15 Chicago....$5.67 Pittsburgh...$4.65

Concheads, same sizes:
New York...$5.75 Cleveland...$5.25 Chicago....$5.77 Pittsburgh...$4.75

MISCELLANEOUS

GREASES—Prices are as follows in the following cities in cents per pound for barrel lots:

	Cincinnati	St. Louis	Birmingham	Denver
Cup	7.2—8.2	7	8	12½
Fiber or sponge	7.2—8.2	..	8	20
Transmission	7.2—8.2	7	8½	20
Axle	4.6—4.9	4	4	5½
Gear	4.9—7.1	..	8	9
Car journal	4.9	..	5	8½

	New York		Cleveland		Chicago	
	Current	One Year Ago	Current	One Year Ago	Current	One Year Ago
Best grade	95.00	70.00	93.00	70.00	96.00	70.00
Commercial	50.00	40.00	23.00	24.50	25.00	25.00

HOSE—Following are prices of various classes of hose:

Fire

	50-Ft. Lengths
Underwriters' 2½-in.	75c. per ft.
Common, 2½-in.	40%

Air

	First Grade	Second Grade	Third Grade
¾-in. per ft.	$0.55	$0.30	$0.25

Steam—Discounts from list

First grade 30% Second grade 30–5% Third grade 40–10%

LEATHER BELTING—Present discounts from list in cities named:

	Medium Grade	Heavy Grade
St. Louis	45%	35%
Denver	35–5%	30%
Birmingham	35%	35%
Chicago	45%	40%
Cincinnati	40–10%	40%

RAWHIDE LACING—25% off list.

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$0.99
Asbestos for high-pressure steam	1.76
Duck and rubber for piston packing	1.10
Flax, regular	.99
Flax, waterproofed	1.21
Compressed asbestos sheet	1.10
Wire insertion asbestos sheet	1.30
Rubber sheet	.66
Rubber sheet, wire insertion	.99
Rubber sheet, duck insertion	.55
Rubber sheet, cloth insertion	.25
Asbestos packing, twisted or braided, and graphited, for valve stems and stuffing boxes	1.21
Asbestos wick, ½- and 1-lb. balls	.75

WIRE ROPE—Discounts from list price on regular grades of bright and galvanized are as follows:

	New York and St. Louis
Galvanized iron rigging	+20%
Galvanized cast steel rigging	List
Bright plain rigging	30%
Bright cast steel	17½%
Bright iron and iron tiller	5%

MANILA ROPE—For rope smaller than ⅝-in. the price is ½ to 2c. extra; while for quantities amounting to less than 600 ft. there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: ⅜-in., 8 ft.; ½-in., 6; ⅝-in., 4½; ¾ in., 3½; 1¼-in., 2 ft. 10 in.; 1½-in., 2 ft. 4 in. Following is price per pound for ⅝-in. and larger, in 1200-ft. coils:

Boston	$0.33½	Birmingham	$0.39
New York	.36	Denver	.36
Cincinnati	.33½	Kansas City	.34½
Chicago	.34	Seattle	.33
St. Paul	.34	St. Louis	.34½
San Francisco	.32	Los Angeles	.34

PIPE AND BOILER COVERING—Below are discounts and part of standard lists:

PIPE COVERING

Pipe Size	Standard List Per Lin. Ft.
1-in.	$0.27

Volume 14 New York, November 14, 1918 *Number* 20

The War Is Won, Now Let Us Win the Peace

PEACE has its problems not less acute than war, especially the peace which immediately follows a conflict. The reason why peace has such dangers is not so much because it is inherently dangerous—for it is not—but because the public prepares itself for an immense reconstruction and does not exhibit the patriotism of the war period in meeting the problems of peace as they arise. If people would only say that business will go along as usual after the war, there would be no danger of any disturbance.

Unfortunately, there are some unwise persons who believe that peace will furnish an opportunity for wage adjustments. There are labor men who scheme to seek raises in wage, and there are manufacturers and operators who expect reductions. All such unwise spirits who seek their own and not their nation's advantage are to be severely reprobated.

The cost of living and of commodities will not change markedly, as some are prone to think. It is based on wages, and these must not be meddled with. If wages are raised, the cost of living must go up, so what is the advantage to labor in raising them? If wages are lowered, profits will not be increased, for prices will go down with wages, so where is the advantage to capital in reducing the size of the fortnightly pay? Every good citizen will do his best to keep both wages and prices stationary, as a change in either will work to the detriment of us all.

There is the threat of foreign competition, but it is remote in time and will probably never eventuate. No one will be able to fill the insatiate need of the world for a long time. There are no large stocks on hand to be dumped in our markets, and before Europe can become settled and have goods to ship here in quantity the wages of Europe may be lifted almost to the American level.

It must be remembered that never was there a time when wealth was so great or so generally distributed. Everyone today owns a bond. So everyone has buying power should any dislocation of industry lay him out of work. There are the means in hand, therefore, for correcting any temporary trouble. Nearly every corporation has its nest egg. Usually up to their necks in debt, corporations are in general marvellously woebegone organizations. During the months of war most of the corporations have provided themselves with Liberty Bonds which would strengthen their position should any slackness intervene, for it would furnish excellent collateral for a loan. So neither individuals nor corporations will have at any time any need to slacken their buying.

During the war all kinds of public work have been delayed. We do not wish to see a lot of unreasoned construction, but much is highly necessary for the national welfare. Schools, roads and railroads demand large expenditure. Whatever is necessary should be done, and we may well prepare to anticipate some of the needs of the future so as to provide work in case the public might be disposed to delay private work pending developments.

But such plans should be carefully labeled "For Emergencies Only," and care should be taken lest the public, having seen the preparations and estimates being made, should insist on the completion of the work involved long before the need for such employment of labor is actually felt. Unfortunately, as there are those who lay their plans to profit, rightly or wrongly, on all public improvements, there is always a disposition to build what has been planned whether a proper occasion presents itself or not. Thus we often find some needless construction standing in the way of the performance of far more necessary work.

America has few reconstruction problems, for she has few war-made cripples, she has few women in industry, and she has suffered but little from the war. The struggle did not last long enough to put us on an ultimate war basis. Not nearly as large a body of men as in Great Britain and France have changed their wonted occupations. For these many reasons there is no occasion for any manner of apprehension if everybody from one end of the country to the other will "sit tight" and not attempt any radical changes or wait for such changes to occur. We have patriotic duties still before us. Let us not fail to be as true to the State in peace as we have been in war. Peace does not in any way absolve us of our citizenship.

IDEAS AND SUGGESTIONS

Method of Working Thick Coal

BY M. STAFFORD
Chase River, Vancouver, B. C.

At present the deep workings of the Canadian Western Fuel Co. at Nanaimo, B. C. (somewhere around 1000 ft.), are in the Douglas seam and extend over large areas. The thickness of the coal varies from almost nothing to over 30 ft. within a distance of less than 100 ft. This variation is caused by irregularities, sometimes in the floor and sometimes in the roof, in other instances in both. The method of working these thick pockets (by "thick" is meant anywhere between 10 to 26 ft.; above that height the coal is very seldom taken on account of the length of timbers required in mining it) is by "straight face"; that

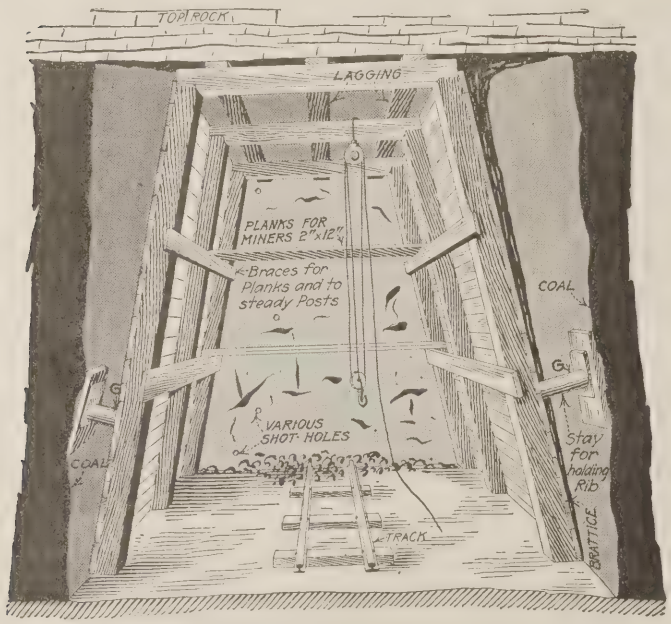

FIG. 1. WORKING THICK COAL FROM PLATFORMS

is, the face is worked as nearly vertical as possible, shooting the bottom out and then putting the perpendicular 6-ft. holes as high as the miner can conveniently reach; the top coal is mined by drilling the shot holes from planks or platforms, as in Fig. 1. Some of these places require as many as three platforms, which rest on planks nailed to the posts.

The work is very tedious. The repeated climbing up to examine the coal face and roof to get down any loose material takes a lot of the miner's time, and this is especially so while timbering. Two men can handle the timber up to lengths from 12 to 18 ft., according to weight, but above these lengths they usually provide themselves with double or single blocks and about 70 ft. of ⅝-in. rope. Sometimes they are able to run a "set" up between loading cars, at other times on account of the distance between the last "set" and the face exceeding 4 to 5 ft., the loading must wait until the timbering is finished, which takes two good men about half a shift.

In this method of working the sides are neglected as it is impossible to reach them to trim off the loose coal. Consequently, at times the short timbers *G* have

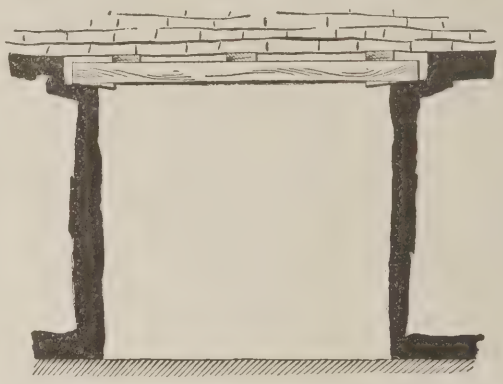

FIG. 2. MINING BY BENCHES—COLLAR HITCHED INTO RIB

to be put in from the rib to the posts. Any pressure from the sides tends to force out the posts. Sometimes the rib gives way, smashing the plank supports and letting down the platforms onto the miners; at other times the roof and top coal fall and cause injury. So you see the miner by this method has no control of his roof or ribs, two points of vital importance in mining. I may add that the company spares no expense in the matter of safety. Anything that the miner desires in this respect is provided. "Safety First" is the slogan, which accounts for so few accidents. So much for that method.

Another method of working thick coal known to many

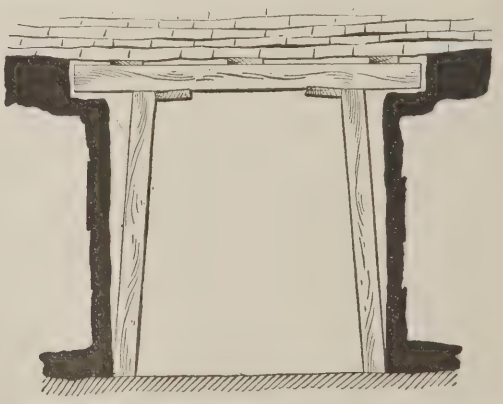

FIG. 3. BENCH MINING—THREE-PIECE SET TIMBERING

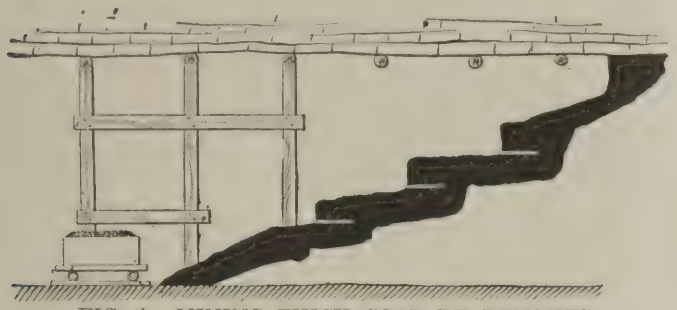
miners is shown in Figs. 2, 3 and 4. To the writer it is preferable on account of the miner always having control of the roof and sides; working in comfort; less anxiety about falling roof and sides, and easier timbering. You will see that the collars, Fig. 2, are hitched into the rib, the miner beginning work next to the top and mining the seam in benches, Fig. 4; standing on the loose coal he can trim the sides up pretty well with

the pick. After loading up his loose coal, he erects long posts which can be notched to fit other notches in his bar, if so desired; or cleats can be nailed to the bar as shown in Fig. 3, to form a notch. Another great advantage of this method is that cars do not have to be stopped, the miner can load and timber alternately. When from four to eight places in a district are all timbering at the same time, as sometimes happens, the output falls off considerably.



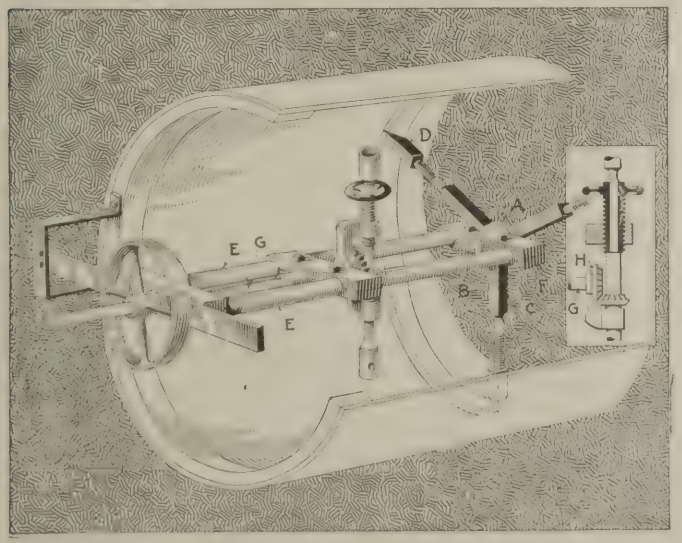


FIG. 4. MINING THICK COAL BY BENCHES

As regards the first method there are the following disadvantages: Danger of roof and sides falling, excessive climbing, danger in working from and upon planks, slower timbering and shortened output, and danger from falling picks and drilling tools. As to the second method, there are the following advantages: The miner has better control of the roof and ribs, the timber is easier handled, the method is safer and greater output can be secured.

A Special Drilling Device

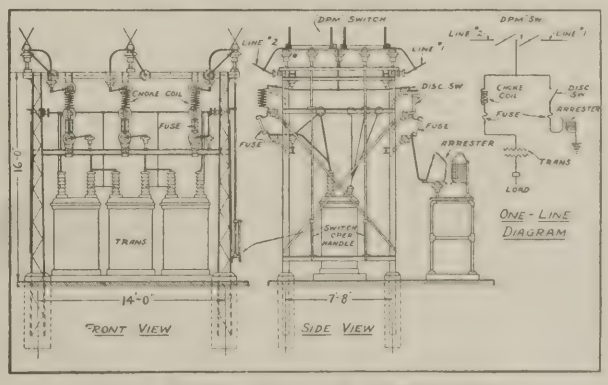
By J. A. Lucas
Ozone Park, N. Y.

The accompanying illustration shows a device that has been found of advantage when it is necessary to drill a hole from the inside of a boiler or tank. *A* represents a base piece made with a journal stud *B*.

DETAILS OF A SPECIAL DRILLING DEVICE

This base piece is provided with a radial arm *C*, with threaded ends and units made with conical projecting ends, as shown at *D*. One of these pieces is used at each end of the machine, when convenient, for entering and holding the frame. When not convenient to use two of them, one end of the frame is sustained as shown in the illustration or in some other manner that may suggest itself.

The casting *F* is made of two pieces and is provided with a bearing for the pin *B* and holds the ends of the rods *EE*. The actuating shaft *G* carries the bevel wheel *H*, more clearly seen in the figure at the side, which drives the drill spindle, whose ends are of different lengths for convenience in reaching to different distances. The cross-head may be slid along as required on the rods and the revolving frame and the drill turned around to different positions.



Outdoor Mine Substations

By H. W. Young
Chicago, Ill.

When considering the purchase of power from a transmission system one of the important points requiring attention is the type of control and protecting equipment. The outdoor substation is rapidly being adopted for this class of service, as it has the advantages of low cost, safety and simplicity, which appeal to the operating man.

The 33,000-volt, three-phrase, 900-kv.-a. design shown in the accompanying illustration is applicable to many installations, as it provides for two sources of power supply and thus insures greater continuity of service.

The steel framework is made up in standard sections easily assembled at the point of installation—the desired base dimensions being secured by longer or shorter connecting cross members.

COAL MINE OUTDOOR SUBSTATION

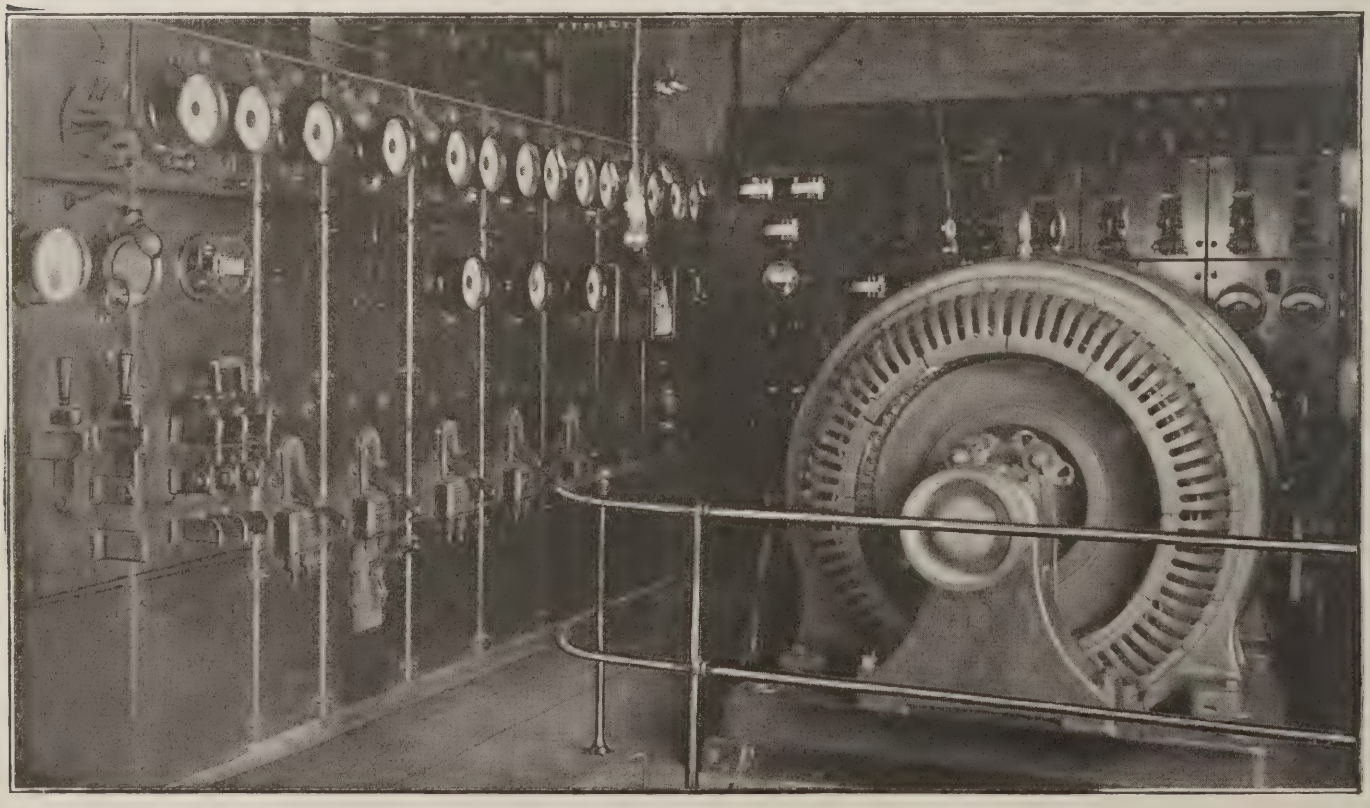
The high-tension control and protecting equipment consists of standard-unit type switches, choke coils, fuses and resistance-type horn lightning arresters connected as shown on the one-line diagram. The switches can be opened or closed from ground level by means of a handle and can be locked in either the open or closed position.

This type of station has the advantage of insuring quick assembly, and when desired the footings can be so made that the equipment can be quickly moved to a new location. The construction is so simple that ordinary labor can be employed for both installation and operation, and since all parts are in plain view inspection from ground level can readily be made.

Keep the boys smiling! Help them while away the lonesome moments by contributing to the War Activities Fund.

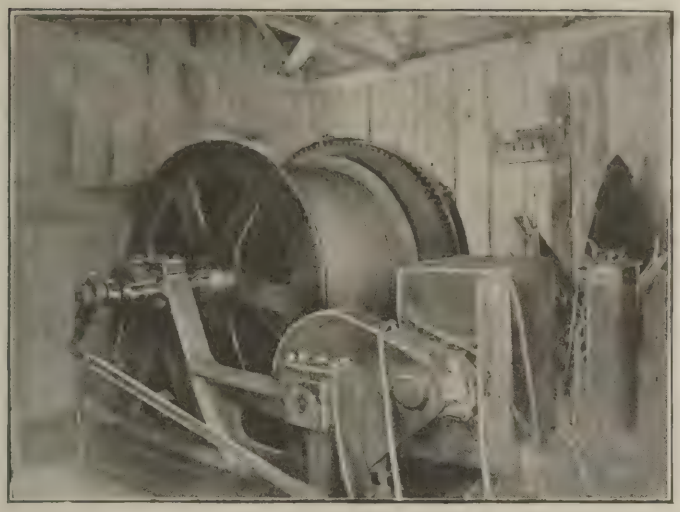
Progress of Electricity in Coal Mining

By FRANK HUSKINSON
Trinidad, Colo.



SYNOPSIS — *The great strides made in the use of electrical equipment around the mines has been due to its inherent advantages over other forms of power distribution. Some of these, as well as the various types of equipment most in use, are here enumerated.*

IN THE early days of the coal industry the low cost of fuel and a general familiarity with the use of steam fostered the emloyment of steam engines of various types for hoisting, pumping, ventilation, surface haulage and the driving of conveyors, breakers, tipples, etc. The use of steam underground has, however, always been both difficult and costly, and with even a limited application there it serves to diminish the factor of safety in an industry in which potential danger to workmen must always be considered.



Compressed air for underground work met some of the objections to the use of steam, and as a result was extensively used for this class of work until the advent of electrical service. This at once rendered possible the application of a single form of power to all classes of machinery, both on the surface and in the mine itself.

The use of electricity in coal mining is not new, as it has been employed to a limited extent for many years, but the rapid extension which has recently characterized its application has been due to several causes, the more important of which can be briefly outlined as follows: (1) The improved efficiencies of modern electrical machinery in general, and the increasing use of alternating current with its greater flexibility in transmission over distances beyond the economical limit of direct current distribution. (2) The specialization of electrical machinery for the power requirements peculiar to coal mines. (3) The notable operating economies that have resulted in numerous installations utilizing electric power, even under the severest conditions, and the attainment in practically every case of an increased output for a given power consumption. (4) The necessity for the development of coal fields in which the geological conditions were such that the mines could not be economically operated by the older methods; also the continually increasing distances between the working faces and the delivery points in mines already in operation have tended to render electric haulage practically imperative.

That the foregoing causes have been given the practical consideration which they deserve is demonstrated by the fact that in recent coal-mining developments of appreciable size electricity has been adopted as a source of applied power either wholly or in part. In many of the older mines it would be true economy to scrap a large percentage of the old steam power equipment and replace it with electrical machines. In some cases, however, mining companies are not fully aware of the inherent economy of electric service and its practically universal applicability. They are therefore disinclined to supersede older equipment which, while admittedly not economical in its operation, has proved its utility.

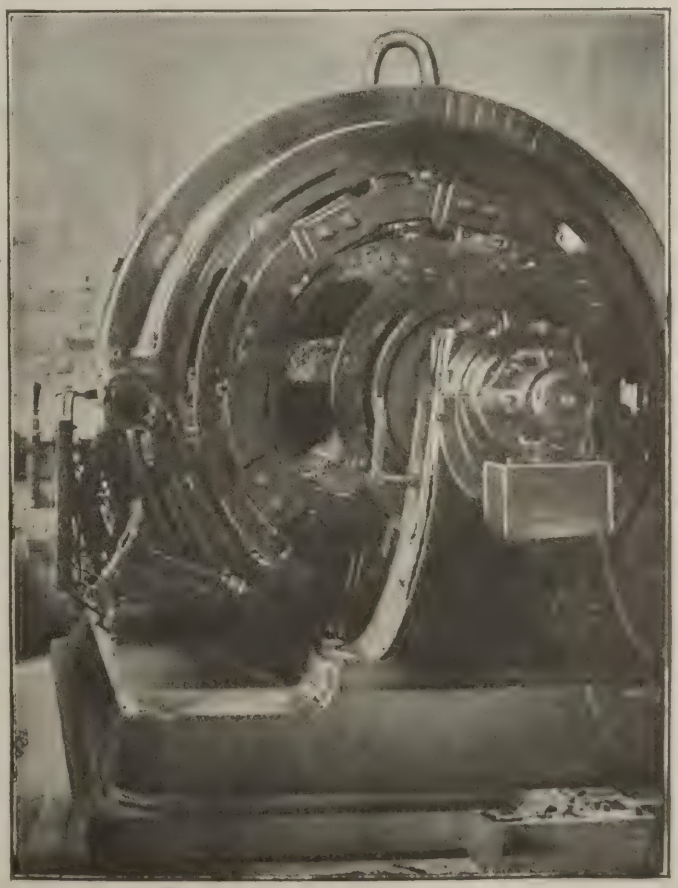
MOTOR-GENERATOR SET AND SWITCHBOARD IN A MINE SUBSTATION

SMALL ELECTRICALLY DRIVEN MINE HOIST

As a logical demonstration of the value of electricity in coal mining this article attempts the explanation of the advantages of the electric drive for all classes of coal-mining machinery. Typical examples are given of the application of motors, the use of both alternating-current and direct-current generators, motor-generator sets and rotary converters.

Power is required in the production of coal, primarily for undercutting, ventilating, transporting, hoisting, pumping, signaling, and the operation of the tipple and other outside machinery. In the electrically operated mine or group of mines, all the machinery may be served from a single power plant. No other general field of power usage imposes upon the electric generator the severity of conditions inseparable from mining service. Nothing can be more trying, for example, than the common instance of a generator supplying power for the operation of mine locomotives. This work calls for instant and frequent changes from no load to full load and usually to a considerable overload. The requirements for a generator that will give satisfactory results in mining service is a capacity for endurance of heavy loads suddenly applied, as well as large overloads applied with equal suddenness and continuing for long periods of time.

The voltages in use range from 220 to 500 volts, for all direct-current installations underground and on the surface. Generators are as a rule compound wound, as it is desirable to have the voltages at the machines increase with a heavy load, so as to keep the potential constant at distant points in the mines. The standard practice in operating two or more direct-current generators is to connect them in parallel. When thus connected, electric generators should be of the same design and construction, and should possess the same or as nearly as possible the same characteristics in order to secure the best results.



The coal-mine operator in the past few years in many instances has come to regard the purchase of central station power as a more satisfactory and economical means of operating his mines than its generation. This removes the worry and care of a power plant, is the means of lower cost of operation and secures greater reliability. This means greater production while increased power can be obtained quickly at a small initial cost. The average coal-mine operator formerly believed that the power produced at his power plant was at a fairly low cost, because of cheap fuel, simple apparatus, cheap labor and the low cost of completed buildings.

The cost of fuel is of course low at the mine, but its value should be figured at the price that could be obtained for it if sold. The water-supply question is often a serious one. Some of the early plants were compelled to have all the water for use in the boilers and elsewhere transported a considerable distance by rail. Again, the water that is found at the mines is often so bad that it causes corrosion, pitting, foaming or scale in the boilers. In many cases this occasions heavy repairs and results in accidents and shutdowns.

The boilers, engines and generators as a rule are the simplest and cheapest obtainable. In many of the early plants at the mines the first cost of a piece of machinery was the only item considered, there being little incentive for high economy at such a power plant. Low cost and reliability are the first requisites, and with the class of unskilled help generally found about the mine reliability can be obtained only with the simplest kind of apparatus.

With the use of "central station power" the old power house is either removed or converted into a substation. The steam engines are replaced by large synchronous motors and belted to the old generators. The old switchboards are used as before, with the addition of new panels to handle the alternating-current motors and other circuits.

The rotary converter is the most popular means of converting the alternating to direct current. Its use in connection with central station power has been found

ROTARY CONVERTER IN A MINE SUBSTATION

to have certain disadvantages that are overcome to a certain extent by the employment of a motor-generator set. As a rule the local conditions are taken into consideration in determining which is the better for the purpose.

The motor-generator set has a decided advantage over the rotary converter in special cases, since there is no electrical connection between the two elements, and independent voltage adjustment over a wide range is possible. Regulation is not greatly affected by the fluctuations of the supply current. The ratio of the direct-current voltage to that of the alternating current in a rotary converter is practically a fixed quantity. This is a serious disadvantage where it is desirable to have the direct current potential increase with the load so as to keep it constant at some distant point. Adjusting the field rheostat or strength of the fields of a rotary converter changes the phase of the current. A lagging alternating current passing through an inductive circuit causes a decrease in the voltage, while a leading current causes a rise.

The superiority of the electric locomotive for mine haulage has caused it to supplant almost all other means of transporting coal inside the mines. This is largely due to the fact that in addition to its high efficiency, mechanical strength, dependability and simplicity of control, it is the most compact form of tractor available. This last characteristic is of the utmost importance in underground operations where the available headroom is usually limited.

HAULAGE AND GATHERING LOCOMOTIVES AT THE MOUTH OF THE MINE

The electric locomotive for mining service is built in various types and sizes. Four general forms are now commonly used. The standard and the most practical as well as the most successful drive is the friction, or electric traction locomotive. This type of machine can be used on good tracks with grades up to 5 per cent. and at times on even greater inclinations. The gathering locomotive is practically the same style of machine, being equipped with either a cable reel or an auxiliary motor, drum and cable. The rack-rail drive is used for heavy pitches met with in some mines. One combination locomotive is a rack-rail and friction drive machine. This type finds application where the track is both ordinary and steep, these conditions being encountered in some hilly mines.

For the main haulage in mines the mule or horse has been almost universally discarded where electric service can be obtained, inasmuch as a single locomotive can effectively displace a considerable number of animals, can travel faster, requires less headroom and can operate 24 hours a day. For gathering, however, animals are still used to some extent.

The standard mine locomotive motor equipment consists of two direct-current units, each connected to a driving axle through a single reduction gear. Three motors are sometimes used with three pairs of driving axles and wheels. It is only in exceptional cases, where the generating and auxiliary motor equipment of a mine is all built for alternating current, and a heavy investment would be required for rotary converters or motor-generator sets, that locomotives utilizing polyphase induction motors can be adopted with success. The necessary speed control would then be secured by a variable external resistance connected in the rotor circuit.

Owing to the high speeds characteristic of this type of motor it is necessary to interpose double reduction gearing in order to obtain the running speeds that are safe for mining service. Two overhead trolleys or a double trolley are also required. Bonded rails may be used for the third conductor. The electric locomotive is a much more flexible system of transportation and more convenient than the rope haul. Electric locomotives are made in many various types and sizes, so that it is possible to find a machine that will operate and give satisfactory results and service in any mine or under any ordinary conditions.

For haulage in slope mines or in drift or shaft mines where the different levels are connected by slopes of considerable length, the locomotive cannot be used, and recourse is had to various forms of rope haulage with permanent hoisting drums located either on the surface or in underground chambers. Due to its rotary motion and high torque characteristics, the electric motor affords an ideal method of applying power to hoists. For this purpose, either direct- or alternating-current motors have numerous advantages as compared with steam and air systems.

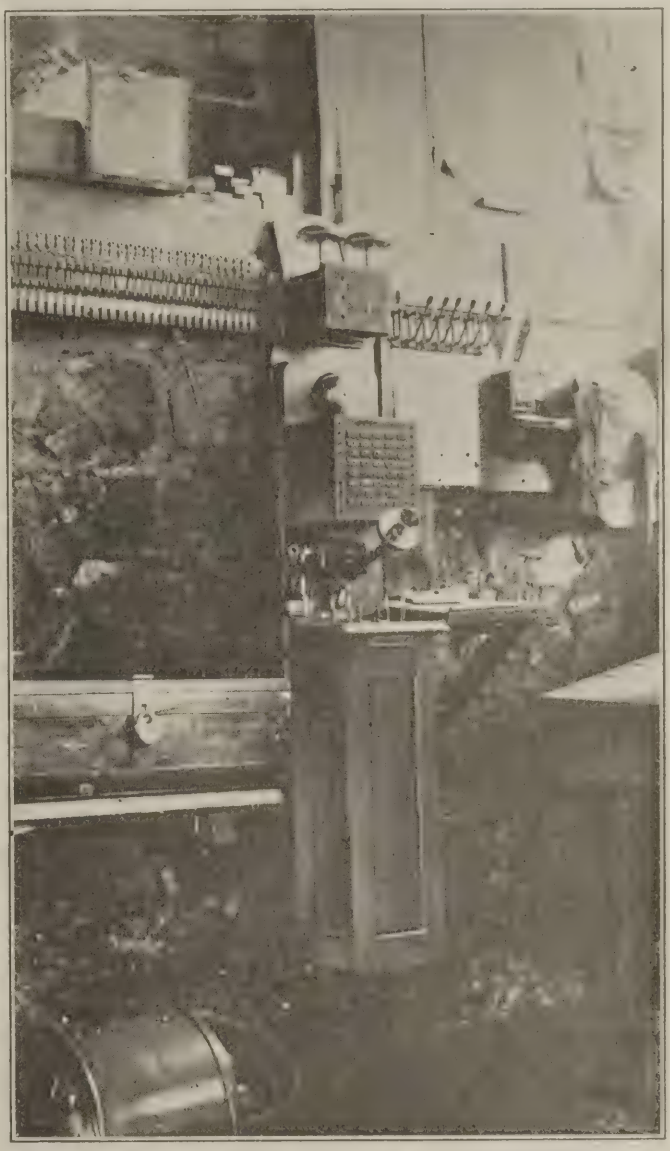
The intermittent service of hoists involves a necessity for certain precautions in running and resuming the operation of steam hoists after they have been shut down, which are entirely absent when the electric type

is used. The motor-driven hoist is the simplest and most compact form, inasmuch as the motor to drive it can usually be mounted on a common base with the hoisting drum and arranged to drive it directly or through gears, thereby forming an entirely self-contained unit and effecting an economy in weight and in the amount of space required for its installation. This is often of appreciable importance when hoists are placed within the mine. Owing to the superior speed control of the electric motor it has great flexibility in operation, while its simplicity minimizes the amount of repairs and obviates the necessity for the services of an experienced engineer to run it.

The relative importance of the pumping equipment in different coal mines is dependent upon the geological conditions encountered. In many mines the service required constitutes a comparatively negligible demand on the power station. On the other hand, a large percentage of the mines situated below local water levels are absolutely dependent for continuous operation on the efficiency of their pumps.

As in the applications already referred to, the electrical operation of pumps renders possible economies and efficiencies otherwise unobtainable, and the benefits derived as compared with either steam or air power service increase in direct proportion to the diversity of the applications and the distances over which power has to be transmitted.

The problem of the main pumping units in coal mines is simplified by the recent improvement in the efficiencies of multi-stage centrifugal pumps. These were formerly only applicable to comparatively low head service, but are now successfully delivering water from sumps located more than 1000 ft. below the surface. The high speeds which are characteristic alike of the electric motor and the centrifugal pump render it a simple matter to design an effective combined unit.



Existing pumps, originally designed for steam operation, are sometimes changed to motor drive. This reduces the amount of power required and the expense of attendance necessary, since such machines can be safely made automatic in operation, if desired. Where motors are geared to reciprocating pumps their use insures the direct application of a larger percentage of the initial power developed than where other methods are employed. Both alternating- and direct-current motors are readily adapted to all forms of pumps, the type of motor selected depending upon the service required and the character of the electrical energy available.

The adoption of the centrifugal type of pump in coal mines is due not only to the improved efficiencies of the modern multi-stage form, but also to the ability of the centrifugal type to handle liquids containing a considerable percentage of solid matter in suspension more successfully than can reciprocating pumps.

A good demonstration of the superior flexibility of electrical operation in coal mines is found in the installation of a portable pumping set. This can be lowered down the shaft or slope, rapidly hauled to any portion of the mine by the electric locomotive and immediately put into service by connecting the suction pipe, unreeling the discharge hose and connecting the motor to the feeder wires.

Uninterrupted service is the primary requisite of a coal-mine ventilation system. The imminence of the hazard to workers underground involved in a failure of the supply of fresh air is of course dependent on the character and formation of the mine. Mechanical ventilation by means of rotary blower or exhaust fans which give a positive and fully controllable supply of air is almost universal in coal mines.

In driving ventilating fans with electric motors the reliability of the service is increased. Mine fans are normally placed only at the mine openings, but in some

SMALL MINE TELEPHONE SWITCHBOARD

mines booster fans are used along the entries or in the air courses. The centrifugal type of fan is the one in almost universal use as a main unit, and as the name implies it is built with the blades parallel to the shaft and forcing the air out at right angles to it. The disk type of fan with radial blades set at an angle to the shaft is used mostly for booster or inside work.

The electric undercutting machine has undoubtedly lowered the cost and increased the production of coal. Approximately 40 per cent. of the production in the United States is mined by machinery. Since the introduction of mechanical coal cutters the use of the electric motor-driven type has increased steadily and more rapidly than other forms, owing to the superior flexi-

bility and economy of the electrical distribution and application of power. The typical modern coal cutter is mounted on a self-propelled truck and all its movements in loading upon or unloading from the truck, and during the process of mining, are made under its own power without hand labor.

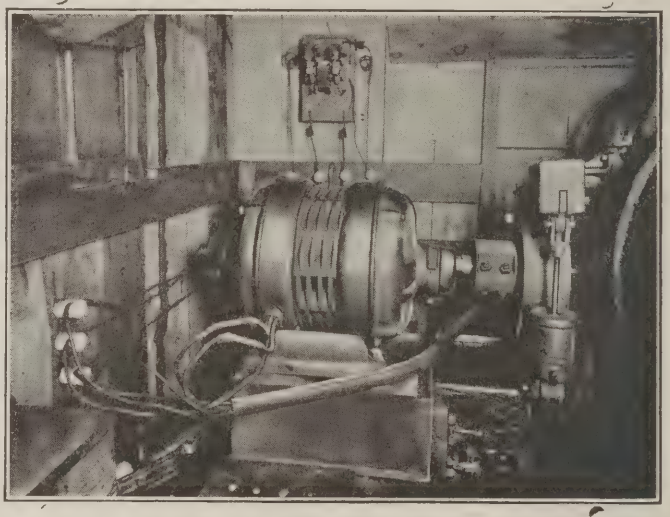
In up-to-date mines the holes for explosives employed in blasting the coal down are drilled quickly and economically by the use of portable electric rotary drills. The electric rotary drill is a powerful, serviceable and thoroughly efficient machine for use in coal. Blasting by electric detonation is the most effective and economical system. It surpasses all others in safety and certainty, as well as in results that are accomplished. Electric blasting makes it possible to fire several charges simultaneously.

Signaling service in mining work must be absolutely reliable, in the face of the most adverse conditions. For this purpose primary batteries are used to some extent in connection with bells and relays. Block signaling systems employing electric lights as the warning medium are used in mines employing several locomotives hauling coal from the same section.

A reliable telephone system in a coal mine and around the outside works is an important item. The saving in time and money which such a system effects by reliably transmitting routine orders or when there is a temporary suspension of power, a shutdown of some part of the plant, an accident, or an emergency affecting both life and property, justifies many times over the investment required.

Mine telephones and systems usually consist of several instruments connected to one pair of wires, forming a party line. Local battery magneto telephones are used and signaling is done by a code of rings. The severe conditions encountered underground, due to moisture, gases, acidulous water, etc., make it necessary to provide instruments unusually well protected for this service.

Mining is rough, hard work, and mining apparatus must be exceptionally strong and rugged to stand the strain. Especially is this true of the storage battery for use in mines. The use of the storage-battery locomotive is becoming more widespread of late, with the recent improvements and development of various types of such batteries.



Electric safety miners' lamps are increasing in popularity every day. The greatest danger in mines today is the use of open lights. Artificial light of some sort is necessary, and much ingenuity has been shown in trying to adapt portable electric lamps to this work. Incandescent lamps are used for lighting all important places inside the mines as well as all buildings on the surface. The use of colored lamps to denote dangerous places and safety manholes, signals, signs, etc., is almost universal in the coal mines today. The electric arc lamp and the flaming arc lamp are used to some extent for illuminating large areas of ground or buildings on the surface.

The trolley wires underground are generally supported by special hangers directly from the mine roof, or timbers, except where the height or the unevenness of the roof make it necessary to attach the suspension to a length of pipe fastened either to the roof or the side walls. A suitable insulation is incorporated in the construction of the special trolley-wire hangers so as to prevent leakage of current.

All feeder lines and wiring are installed on porcelain or glass insulators. The locomotives and all motors working underground on direct-current power utilize the track as a return circuit. The rails on the main haulage roads are bonded with a short flexible bond of copper wire compressed into holes that are drilled close to the ends of the rails.

With the advent of the central station power at the mines, the use of alternating-current motors for all classes of drives has increased, both underground and on the surface. Alternating-current power has some speicfic advantages over direct current. It is more flexible in comparison. With direct current only one voltage is available and that is the one that is generated. With alternating-current it is possible to have as many different voltages as desired by the use of suitable transformers, regardless of what the voltage generated may be.

The induction motor, of the constant-speed squirrel-cage type, is used wherever possible. Its advantages

ALTERNATING CURRENT MOTOR DRIVING A SMALL HOIST

over the direct-current machine are numerous. It is the simplest kind of an electric motor and will stand more abuse and give satisfactory service with less attention than any other type. With the elimination of the commutator and brushes the fire hazard and safety conditions are greatly improved.

For tipple service and for box-car loader drives either alternating- or direct-current motors may be used. In the direct-current installations the use of compound-wound motors is the accepted rule in almost all cases. The constant-speed type of induction motor is used extensively for operating picking tables, drags, conveyors, shaking screens, etc. In fact they are the universal drive for all machinery and apparatus that requires practically a constant and uniform speed. The variable-speed wound-rotor type of alternating-current motor is used for drives that require excessive starting torque and that are subject to stops and sudden reversals.

In general electric motors afford the most satisfactory form of power for driving machinery of all classes. This superiority is due to several causes, among them being the following: The economy with which electric

energy can be generated in large central stations, transmitted over wide extents of territory and delivered to the most remote user in a form suitable for his purpose; the high operating efficiency of electric apparatus; an electric motor is one of the most efficient of energy transforming devices while operating, and the instant it stops all expense for power ceases; the ease and certainty of control and the small amount of attention required.

The control of an electric motor is the acme of simplicity and can be effected by almost anyone. In fact the operator need not be near the motor he controls, but can start and stop it from a distant point. Furthermore, in many instances an automatic controller can be arranged, thereby making the starting and stopping automatic and dependent upon current conditions and the work to be performed.

Who's Who In Coal Mining

James Brown Neale

James B. Neale, the Fuel Administration Production Manager, is a man whom the war surprised. He was not extensively known before he was appointed to his present office. He was one of the men who were, and even still are, practicing in a narrow sphere a work which could be expanded into one of national scope and importance if the opportunity were offered. The workers of the Buck Run Coal Co. and the Darkwater Coal Co. near Minersville, Penn., watched Mr. Neale around the breaker and down in the mine dressed in his mining clothes and they little thought of him as the man who would later be production manager for the United States.

An energetic man, he lived at his work and stayed by it night and day. The advice he gave to the West Virginia operators to stay "close to the game" (he did not use those words exactly) was the advice he followed himself as an operator in so far as that was physically possible, for he had general charge, as president, of not only the Buck Run and Darkwater operations in the anthracite region, but over the Sonman Shaft, near Johnstown in Cambria County, Pennsylvania, and over the Canmore mine, in far-away Calgary, British Columbia.

James B. Neale was born on Oct. 4, 1872, in the town of Kittanning, Penn., a few miles north of Pittsburgh on the Allegheny River. His father was Alonzo Potter Neale and his mother Martha Elizabeth Colwell. He was educated at Yale and received his A.B. degree in 1896, being admitted later to the bar. In due time Mr. Neale became a member of the coal firm of Thorne, Neale & Co.

Mr. Neale has, at no time, been robust, yet there is in him that spirit which drives him along unceasingly despite the weakness of the physical framework which holds it. The bedplate of his engine is somewhat too light for the large diameter cylinders and high-pressure steam which shock and jar it, but it nevertheless has, so far, contrived to hold its own. Buck Run and Darkwater collieries in the steeply dipping folds of the southern anthracite field are not quick-yielding or easily mined propositions. When in 1903 the Buck Run Coal Co. opened the Buck Run mine, every mining man in the valley predicted for it a short life. But their fears were groundless as the present going colliery will show. Darkwater had been abandoned, but Mr. Neale's company reopened it and it is running successfully today.

At Buck Run Mr. Neale erected a fine clubhouse and a beautiful school building. When the fire of a year ago destroyed the breaker, it ruined also a fine washhouse and convenient first-aid quarters. At Buck Run a trained nurse is provided for the sick and injured residents of the village. The miners' homes are small and the wild nature of the surroundings prevents gardening, but these disadvantages are more than offset by the recreational opportunities provided. A saving fund has long been a feature at this colliery, the money being kept as in a bank subject to the depositor's call.

Mr. Neale asked no more in West Virginia than he has provided for his own men in Pennsylvania. But he

JAMES B. NEALE

knows as well as any man that "plans of mice and men gang aft agley" and that no matter what is done to solve the labor problem there will be some labor troubles to make mining difficult. When he was touring West Virginia, the men he had served so well at Buck Run, mostly Lithuanians, a class of men always ready for any trouble presenting itself, went out on strike with the other mine workers in the southern field.

The production of coal is often not so much a technical problem as a moral issue. In war, coal supplies the army, the navy and the nation; in peace, it is the motive power from which come our comforts and our sustenance. Who shall say that the filling of such an important part of the national and world needs as is the supplying of coal is not a duty preëminent among the many we owe to our neighbor? Only a man of Neale's temperament and qualities could have achieved the great work which he has done to sustain and increase tonnage or could have given to the great army of coal mine workers and operators their wonderful morale during the continuance of that struggle which appears to have just reached its close.

Research and Progress in Byproduct Coking in Great Britain—II

By J. B. C. KERSHAW
Colwyn Bay, Liverpool, England

SYPNOSIS—*Coal tar is an extremely useful and interesting substance. Its distillation into various substances such as naphtha, creosote, anthracene, etc., is a process presenting many possibilities for improvement. At present the intermittent process is mostly employed, but continuous distillation would yield many advantages.*

IN THE PAST large quantities of the crude or raw tar produced in byproduct coke ovens have been used in England for road-making, while in America it has been employed as a substitute for solid or liquid fuel in metallurgical operations; but this can hardly be considered a satisfactory or scientific method of disposing of this valuable byproduct of the coking industry. Distillation, for the purpose of recovering some or all of the various constituents that form the base materials of several important branch manufactures, is therefore now regarded not only as the more patriotic, but as the more profitable course to follow with regard to this product.

The explosive, aniline dye, synthetic drug and perfume industries are all based on substances derived from tar; and although the popular idea that the beautiful colors manufactured from tar are already really contained in this material as it leaves the gas or coke works where it is first produced is quite erroneous, it is nevertheless true that without cheap and adequate supplies of tar to provide the base materials—benzol, toluol and anthracene—the dyeing and explosive industries could never have attained their present development in Germany, England and America.

Tar Most Remarkable Compound Known

In 1897 Germany obtained only 52,000 tons of the tar she required to support her color industry from coke-ovens, whereas ten years later, in 1907, she obtained 632,400 tons per annum from this source and another 300,000 tons from gas works. The tremendous expansion of the byproduct coking industry in Germany during the next decade—the ten years 1908-1917—of course explains why she is now practically independent of the rest of the world as regards supplies of benzol for her great explosive and color works.

Tar is regarded by the general public as a nasty black viscous substance, with an evil odor and a reputation for spoiling children's clothes. To the chemist it is one of the most remarkable compounds known, being a mixture of hydrocarbons, both aromatic and paraffinoid, with certain oxygen- and sulphur-containing compounds of acid character, also some nitrogenous compounds with basic properties. The fact that tar contains comparatively large quantities of benzol and anthracene, two important organic bodies, with the carbon "ring structure," explains why tar is such an important material for the synthetic drug and color industries. Nearly all these valuable derivatives are based on the benzene "ring" discovered by Kekulé in 1865. It was this discovery, and the preliminary work required to establish the ring theory of structure for these higher hydrocarbons, which led to the rapid development of the color industry in Germany, rather than in England or France.

The composition of coal tar is so varied that no one analysis can be accepted as representative, but as a rule its specific gravity varies from 1.1 to 1.2, and the higher the temperature used in coking the greater the percentage of anthracene and pitch. The character of the coal used, the shape of the ovens or retorts, the compression used in charging them and the temperature of carbonization all have some influence upon the character and composition of the tar.

Tar Should Be Kept Free from Contamination

It is important that before the tar is subjected to distillation it should be freed from the ammonia water that has collected or condensed with it. This separation of water from the tar by settling, however, is sometimes hindered by the presence or the tar oils, used for extracting toluol and benzol from the gas, since these oils produce an emulsion with the water and tar. In order to obtain a good separation it is necessary, therefore, to make certain that no tar oil from the benzol-recovery plant has been allowed to contaminate the tar.

If the tar is intended merely for road-making uses, the products that are removed by distillation are ammonia liquor, benzol, toluol, solvent naphtha and carbolic acid; the heavy creosote oils and anthracene oils being left. The tar distillation plants that have been erected at many English gas works in recent years are for this purpose, and the tar produced is sold to meet the road board's specifications for "road tar."

The tar prepared under this scheme would probably be classed in America as "soft pitch." It leaves the still at 260 deg. C. in the fluid state, and passes through a "heat interchanger," in which it gives up some portion of its surplus heat to the inflowing cold tar. The aqueous vapor and light oils driven off during the distillation are also first condensed in a cast-iron coil immersed in cold tar, so that here again some heat is saved and returned to the still with the fresh charge.

The amount of water and light oils obtained from one ton of tar by this process is usually 30 gal. The chief advantage of this method of tar treatment is that it recovers the ammonia and phenols, and provides an outlet for the pitch, which forms 50 per cent. of the total weight of tar distilled in all tar works and is often a difficult byproduct to dispose of. The disadvantages are that the heavy tar oils and the anthracene are also left in the final product, and that these constituents are sometimes more valuable than those recovered.

Each case must be studied therefore in the light of

local conditions. In this connection the following figures from an article by E. B. Wilson in *Coal Age* for Feb. 10, 1917, are of interest. The prices upon which the estimate is based will of course now require revision, for in most cases they have advanced during the past eighteen months.

YIELD AND VALUE OF BYPRODUCTS FROM A CONTINUOUS TAR-DISTILLATION PLANT, USING 10,000 GAL. OR 42 TONS OF TAR PER DAY

	Yield, Gal.	Value
Ammonia liquor (3 per cent.)	273	$8.01
Naphtha	117½	11.76
Light oil	994	94.40
Creosote oil	1772	86.10
Anthracite oil	726½	36.33
Pitch	5500	330.00
Total	9333	$566.60

Since the cost of distilling 10,000 gal., or 42 tons, of tar was only 28c. per ton, equal to $11.76, the receipts work out at $554.84 as compared with $300 if the tar had been sold. A much larger profit would of course be obtained if the crude products named above were still solid it is difficult to handle, and its dust causes a dangerous disease known as "pitch cancer" among the workers.

According to Butler (*Journal Society of Chemical Industry*, Jan. 31, 1918) one of the best methods of handling pitch from tar stills is to run it while still hot and fluid into pans holding half a ton. It is here allowed to cool and set. When cold, by means of a crane the pan and its contents are swung over a railway car and tipped, the whole block of pitch being thus moved from the still to the railway car without any handling.

As regards the treatment of the light-oil fraction, the latest English practice is to wash the oils with dilute caustic soda. This chemical combines with the tar acids to form phenolates and other salts, and on treating the solutions of these with CO_2 the carbolic and other free tar acids separate from the solution of sodium carbonate, which is formed as a result of the reaction.

The larger portion of the light-oil fraction, however, is unacted on by caustic soda and contains the benzene,

GENERAL VIEW OF AN ENGLISH BYPRODUCT RECOVERY PLANT

further refined before sale. This would, however, demand a much larger plant and an expert staff of engineers and chemists to manage it.

English Practice in Tar Distillation

If it be decided that recovery of the byproducts is desirable, the tar by the first distillation may be separated into the following fractions: (1) Below 150 deg. C., ammonia liquor; (2) 150 to 170 deg. C., light oil; (3) 170 to 230 deg. C., middle or carbolic oil; (4) 230 to 270 deg. C., heavy or creosote oil; (5) 270 to 400 deg. C., anthracene oil.

The pitch which remains in the still at the end of the distillation amounts to between 50 and 60 per cent. of the tar used. Its disposal, as already pointed out, is one of the problems of tar distillation. When cold and toluene, xylene and solvent naphtha. All of these are highly valuable byproducts at the present time. These are separated one from the other by further distillation, after a preliminary treatment of the light-oil fraction with concentrated sulphuric acid, in order to remove the unsaturated hydrocarbons and sulphur compounds, which are impurities that would hinder the success of the fractionating process.

The middle oils which distill between 170 and 230 deg. C. consist chiefly of carbolic oils and naphthalene, and on standing some time the latter separates out in crystalline form. The mother liquor from these crystals contains 30 to 40 per cent. carbolic acid, which is recovered by treatment of the oil with caustic soda and CO_2 as described above.

The creosote oils which come over between 230 and

270 deg. C. deposit naphthalene in a crystalline form on cooling and after separating the crystals by centrifugal action these oils are ready for use either as a wood preservative or as a liquid fuel. Naphthalene is purified by washing with sulphuric acid and caustic soda, and is then either redistilled or sublimed in order to obtain a pure marketable product.

Anthracene is separated from the heavy anthracene oil by cooling in vessels provided with mechanical agitation. The greenish crystals are separated from the oily mother liquor in a filter press, and are then passed through a centrifugal machine to remove the last traces of the liquid oil. By treating the crystals in a steam-heated hydraulic press under a pressure of 200 to 300 atmospheres (2940 to 4410 lb. per sq.in.), the bulk of the impurities of the crude anthracene flow away in the liquid form, while the balance can be removed by washing the crystals that remain with solvent naphtha and pyridine. The products of these operations is a 90 per cent. anthracene, which is employed in the color works to produce "alizarene," the base of many important red and purple dyes.

The form of still used for tar distillation is usually a pot still, of 10 to 20 tons capacity, with a dished or concave bottom. In large tar works these stills are arranged in rows of five or ten. In order to economize heat a "preheater" is attached to each still, and in this vessel the vapors proceeding from the still are made use of to heat the incoming charge of tar, while in some cases the pitch as it flows out is also employed for the same purpose.

Satisfactory Type of Still Not Yet Evolved

Many continuous forms of still have been patented and tried, but so far no one type has been generally adopted and the old form of pot still is still used in the majority of tar works. The advantages of continuous distillation, both as regards economy of heat and working expenses are so great, however, it is reasonable to believe that in time all difficulties will be surmounted, and that a satisfactory type of continuous tar-distillation still will be evolved.

A paper read before the American Iron and Steel Institute in 1916, by W. H. Childs, contained a large amount of information upon American methods of working up coal tar. The author stated that in the United States the horizontal type of still was more common than the vertical type favored by European tar distillers. As regards continuous stills, encouraging results had been obtained both in Europe and America, and further experience would no doubt improve the design and operation of this type of apparatus.

Steam or air agitation was generally used in the United States in conjunction, at times, with reduced pressure. In running the still to pitch, five fractions were generally taken—that is, light oil or crude naphtha, carbolic or middle-oil, heavy or creosote oil, anthracene oil and pitch.

As regarded the latter product, American tar distillers had gone in advance of European distillers in producing soft and medium pitches suitable for a great variety of purposes, and large sums of money had been expended upon technical application and the education of the public in the use of these soft and medium pitches for roofing, road-making and similar purposes.

Finally, an American patent for a continuous type of tar still may be referred to. This was granted to R. P. Parry in March, 1916, and is numbered 1,175,079. In this case the tar is fed continuously as a thin film onto a rotating drum or surface, which is kept moving at a uniform rate and is heated to 537 deg. C. (1000 deg. F.). The speed of rotation and the heat applied must be sufficient to drive off all the volatile constituents of the tar, and to convert the residue into pitch coke, which is then automatically removed from the drum as it completes each revolution. A similar device, working under a partial vacuum, has been employed for the preliminary dehydration of tar before distillation. In this case, however, a much lower temperature suffices to drive off the water and highly volatile oils.

(To be continued)

Coal Production in France Since 1913

The production of mineral fuel, including lignite, in France in 1913, was 40,843,618 tons. During the first months of the war, owing to German occupation, all of the Valenciennes basin and the greater part of that of the Pas-de-Calais, with a normal output of about 22,500,000 tons, or more than half of the total coal production of France, were eliminated from the native coal supply. Moreover, the collieries in active operation lost a large part of the miners through mobilization. The production, therefore, during the second six months of 1914 was greatly reduced, and the output in January, 1915, was only 1,532,000 metric tons. The production slowly but gradually increased during 1915 and 1916, reaching 1,676,000 tons in January, 1916, and 1,861,000 tons in December of the same year. The progress was more marked in 1917. The maximum monthly production was reached in October, the output being 2,783,000 metric tons, nearly the normal monthly production before the war. The estimated total French coal production during the past year was nearly 29,000,000 metric tons, or more than 9,000,000 metric tons greater than in 1916.

Normally the annual production of French coal is about 40,000,000 metric tons, and the annual consumption 60,000,000 metric tons, the shortage of 20,000,000 metric tons being made up by the importation of foreign coal. During 1917 there was 17,333,156 tons of coal fuel imported, including briquets and coke, which, with the native production of 28,930,000 metric tons, made the total coal supply of France for the year 46,263,156 metric tons. But owing to the increased activity shown in many branches of French trade during the past year, there was an increased consumption of fuel and the demand was greater than the supply.

Of the imports of coal fuel in 1917, Great Britain shipped 15,848,734 metric tons of coal, 662,662 tons of coke, and 753,772 tons of briquets; and the United States 57,136 tons of coal. The receipts of American coal would have been much larger had the shippers not been handicapped by the prohibitive freight rates which prevailed, owing to the scarcity of available tonnage.

The consumption of coal in France for household and industrial purposes is regulated by statute, preference being given in the allotments to establishments working for the national defense.—*Commerce Reports.*

Hazards and Safeguards in Anthracite Breakers and Washeries*

By D. K. GLOVER
Safety Engineer, Lehigh Coal and Navigation Co., Lansford, Penn.

PERHAPS the most logical method of covering the hazards encountered in preparing coal for market is to follow the flow of the coal through the breaker. At the dump, as the coal leaves the mine car, the hazards are from flying pieces of coal or rock and cars jumping the dump, resulting in injury to the men engaged in removing the latches of the car door. Injuries from flying material can be prevented by inclosing the dump at the sides and top. The jumping of cars is possible on certain styles of dumps, particularly on the old balance or gravity dump. Where this style of dump is used, timber framework should be placed to check the car but not so as to interfere with the dumping. On the Greene dump, the rotary dump, the self-dumping cage and steam dump there is only a remote possibility, if any, of accidents from this cause. On old-style dumps, where wooden cars with end latches were used, it was customary to have a man knock off the latches with a sledge hammer while the car was being dumped; with the rotary dump this is entirely eliminated. On the Greene dump the latch can be loosened while the car is moving slowly; at the steam dump the car latch is partly opened while the car is at rest, and the final opening is made by blocks set at the sides of the dump. Where the self-dumping cage is used, with a steel car equipped with a sliding ring on a horn, it is necessary to pull the ring by hand. In order to safeguard the man performing this duty, he is placed on a platform high enough so that no material from the car can possibly strike him. He is also provided with an iron rod, 8 ft. long, with a U-shaped prong large enough to pass over the horn but not over the ring; and as he stands at an angle of about 45 deg. with the direction of the flowing material he is out of all danger.

Safeguards Protect Platform Men

If the coal is not checked as it flows down the dump chute there is a possibility of it having sufficient velocity to pass over the shakers and strike the platform men. To obviate this two forms of checks have been devised, both of which work very satisfactorily; one is a suspended gate nearly the width of the dump chute, about 4 ft. high, made of 3-in. oak covered with ¼-in. sheet iron. This gate is forced open by the weight of the material resting against the upper side, thus allowing the material to flow under. The other is the slowly revolving feed, which is the width of the dump chute, and consists of four paddles about 18 in. high set at right angles to one another. While this feed is not primarily a safeguard, it acts in that manner on many occasions. To eliminate the possibility of large lumps bounding over the feed and striking the workmen on the picking platform, second-hand 40-lb. T-rails are strung across the top of the platform, these being raised about 2 ft. above the floor to allow ordinary lumps to pass under.

On the first platform, where the class of material handled is large and rough, the possibility of a man injuring himself by straining is eliminated by arranging that he stand so that his waistline is at the level of the platform. To safeguard him from cutting his fingers while pushing rock off into the rock chute, he is provided with either leather mitts or hand leathers; to protect his fingers from pinching when starting a jam, he uses a two-pronged hook.

Leather Gloves Save the Fingers

On the second platform the material handled is finer than at the first platform, as it has already passed through the shakers; the only possibility of accident is the cutting of fingers on sharp edges, and this is eliminated through the use of leather gloves. The chutes are protected near the rolls on which the coal passes, so that in the event of a man carelessly stepping into a chute he cannot slide down to the rolls. The rolls are entirely covered, with the exception of the covered chutes leading into the rolls and the chute under the rolls, thus preventing anyone from accidentally stepping into or falling into rolls and eliminating accidents from flying pieces.

As the rock passes to the rock pocket, the chutes are built with sides high enough to prevent flying pieces striking employees. When the rock is loaded out of the chute, accidents to loaders, who in times past stood in front of the chutes to pull the lever operating the gate, are prevented by the installation of steam rock gates, operated from a platform above; the operator is in an absolutely safe place and performs his work without straining.

The coal, on leaving the main rolls, is again passed over sets of shakers and sized before passing to the jigs. Accidents around shakers usually occur at the shaker shafts while men are oiling. If a railing 42 in. high, with four removable pipe sections, is constructed in the rear of the shaker shaft and the cam straps are provided with grease cups, there is not much chance for an oiler to be caught. Several fatal accidents, in which the victims were wrapped around the shaker shafts, have come under my observation—all due to removal of railings by thoughtless oilers.

At jigs, the hazards consist of being caught around jig shafts, or, in some types, coming in contact with sprockets and chains on the elevators. The first hazard is readily removed by covering the jig shaft, leaving the cams and straps exposed, with the grease cup placed on top of the cam strap; the second, by a guard over the sprocket wheel and chain.

During repairs of the jigs, when it is necessary for men to work inside, there is small possibility of accident, as the repairs are usually made at night when no material is passing through the breaker; or, if extensive re-

*Paper read at the seventh annual congress of the National Safety Council, St. Louis, Mo., September, 1918.

pairs are necessary, the flow of water and material can be diverted without great difficulty.

In the loading pockets, to which the coal passes from the jigs, the only hazard present is when, under extraordinary conditions, the pockets become blocked. It is necessary for a workman to start the coal, and he may be drawn down with the flowing coal and buried. This hazard is safeguarded by the use of a safety belt or by the construction of a walk on one side of the pocket. Another possibility that occurs to me is that of a workman accidentally falling into the pockets. However where a substantial railing of standard height is maintained there is not much danger of such an accident.

The running of cars under the breaker for loading presents several hazards; one is the danger of a car runner being knocked off the car by the lip of the chute. As it is contrary to good principles of operation to have chutes very high above the cars, on account of breakage, and the fact that there is so much variation in the height of standard-gage coal cars, necessitating a chute high enough to suit the highest, it requires caution on the part of the car runner while handling cars under the breaker. Inasmuch as the cars are under control at all times, ordinary precaution and attention are all that are necessary.

Danger Signs Are an Aid to Safety

Another hazard is that of persons being squeezed between cars and the side of the breaker or breaker supports. In breakers that were built before the safety campaign assumed such proportions, wherein the clearance is not very ample—it would require great expense to remodel so large a structure and possibly interfere with production—a danger sign should be posted, warning all concerned of the accident possibilities while the breaker is running. During cleaning-up time, after hours, a man should guard the incoming end of the breaker to prevent cars from being run under the pockets. In new breakers, or at old breakers where interference exists that can be changed, a clearance of 7 ft. from the center of the track on each side should be made.

The foregoing probably covers every stage of the preparation of coal, but there are other hazards that occur throughout breakers and washeries in general. One of the most serious is that of horseplay. Very often boys have been injured while sliding down stair railings; teasing one another, resulting in coal, bolt nuts or other pieces being thrown and either striking the person intended or some bystander; wrestling, pushing through or over protective railings and chasing one another up or down steps. There is no question but that boys will be boys and enjoy fun, but there is room for an educational campaign on the proper way for boys to play, as exemplified in the publications of the National Safety Council. A splendid field for an educational safety campaign is afforded in every school located in a mining community and great benefits would be derived therefrom. Very often it is hard to determine whether or not the injury was caused by horseplay, but when fully proved it is sometimes effective to take advantage of the clause in the Workmen's Compensation Act of Pennsylvania which denies compensation for injuries received while engaged in acts which are not furthering the interests of the employer. This affects the boy's pay envelope, brings his parents' attention to the cause of the accident, and sometimes results in the boy being forcibly reminded of his carelessness. One case that comes to my mind is that of two boys fooling, then quarreling and finally throwing pieces of coal at one another; neither one succeeded in stopping the other until one boy threw a ¾-in. nut. This struck an old man, who was passing at the time, above the eye. Both boys were brought before the foreman, lectured and made to stand equal shares of the man's earnings while he was disabled. Horseplay in this breaker received a great setback.

Another hazard is the use of mushroomed tools by repairmen. The simplest and surest way of correcting this evil is to instruct the smith who sharpens the tools to dress both ends before returning them; also through periodical inspections.

In timber repairs, erecting additions, or construction work, safety belts have proved very satisfactory. In handling material, the heavy parts are usually hoisted in a corner of the building so situated that it is somewhat removed from the operating and frequently traveled part of the building, thus eliminating the hazard of falling material. Where canvas gloves are used by the men handling sheet iron for chute bottoms very few cut fingers result.

Suggestions for Mine Rescue Work

A portable telephone suitable for rescue and recovery crews is an important adjunct to a recovery outfit, especially for a crew that is descending a shaft and combating a mine fire. In recovery work an ordinary mine-telephone set and the necessary wires should be installed and be kept well up to the recovery crews. Such a telephone installation is of great advantage in case the ventilating fan stops and facilitates the sending of material where most needed. In the absence of a telephone, the main entries of the mine should be divided into sections of 500 to 1000 ft., and competent and reliable men should be detailed to patrol each section to give alarm on the occurrence of danger.

Men wearing heavy breathing apparatus should not be called on to transport dead bodies from a mine in case of disaster except in special emergency, and then for short distances only. Their work is to seek living miners, locate fires and rescue the recovery crews should they venture too far.

Some recognized authority must be in charge of the rescue and recovery operations at a mine following a disaster. This power should be vested in a man of good judgment, a cool head, and mild temperament. Such a person will confer freely with the men who have tendered their services and will not hesitate to ask for and receive suggestions. Executive charge will automatically go to the senior official of a mine, or to the state mine inspector, if the latter has arrived. The local officials are generally so much disturbed by the horror of the accident that they are glad to turn over the direction of the rescue and recovery work to the state inspector or to other qualified persons. In the early stages it may be necessary for the outside officials and employees to select one of their number to assume charge until the arrival of some more experienced man, such as the state mine inspector.—*Rescue and Recovery Operations in Mines.*

Increasing Coal Mine Efficiency—V

By CHARLES E. STUART
United States Fuel Administration, Washington, D. C.

SYNOPSIS—*This, the last article of the series on this subject, deals with central station conditions and problems. Many such stations are overloaded during the day, and as additional equipment is difficult to obtain these stations and their war-industry customers are faced with some objectionable but not altogether destructive alternatives.*

IN MANY mine centers served by central stations, as well as in other war-industry centers such as the Pittsburgh and Philadelphia districts, there is a growing power shortage and in other sections an approaching shortage. This fact is due to the rapidly increasing demand incident to the speeding up of industry to meet war necessity. I am familiar with a case where the demand on a central station serving coal mines almost exclusively has doubled within the period of a year.

Fig. 32 is a load curve of one of the largest central stations in the country serving mines. It will be observed that the demand is actually in excess of the present capacity of the generating station. In this particular case the present condition is the result of breakdowns. At the same time the company in question has insufficient reserve capacity and for that reason the failure of one of its larger units is sufficient to curtail service to the entire system.

Additional Units Mean Increased Investment

The question will be asked: Why not increase the generating capacity by additional units? To do this, as a rule, involves heavy investment cost. Many of the utility companies under present operating conditions cannot show a balance that would enable them to finance such an investment. Moreover, where satisfactory earnings are shown, there arises the question incident to the present high cost of apparatus and the relationship of such excessive cost to the conditions that will exist after the war, and particularly when the load falls off.

But even where the financial condition of a company is favorable, as is true in cases, there is involved the impossibility of financing against Government requirements and the difficulty of financing under the rules of the War Finance Corporation.

In spite of these considerations, the central stations are obtaining a great deal of financial assistance where it is necessary. However, even with funds needed for improvement in hand, equipment must be obtained and installed under nearly impossible conditions. There is a demand for turbine equipment far in excess of the supply. A turbine of any size today cannot be obtained within a year. Boiler manufacturers are in the same condition as are the turbine builders.

Where a breakdown occurs there is delay in effecting repairs, even with all the priority assistance that can be given. Furthermore, there is the consideration of skilled labor necessary to look after the complicated requirements of a central station system. Linemen and other similar help are not exempted. The chief engineer or the chief dispatcher in the central station is liable to call on short notice, with attending demoralization to service. All of these facts are focusing the consideration of the mine owners and central station operators toward establishment of measures of relief.

Mine Power Service Receives Priority

In Pittsburgh and Philadelphia recently the office hours of buildings, department stores, lofts and other similar power users have been staggered. No lighting or elevator service, for instance, is allowed to meet such requirements between 7:30 a. m. and 10 a. m. Mine power service in the Pittsburgh district has been given priority over service to all other war industries; thus, the steel mills in the Pittsburgh district are being subjected to shutdowns, while the coal mines are kept running. Non-war loads, such, for instance, as the glass manufacturers, have been required to go on night shift. Certain war loads are doing the same. The steel mills are already operating a night shift.

There are a number of alternatives with which the coal operators, as well as the central stations serving mines, will be faced, as conditions grow more acute. Some of these are enumerated as follows: Placing all non-war loads on night shift, insofar as they conflict with the mining or other war-industry loads. Placing cutting machines and pumps on night shift, where this particular class of load, if so placed, would take sufficient demand from the day load to be of assistance. This is now being done in the West Virginia fields. To stagger the loads—that is to say, start certain mines at an early hour in the morning, other mines a few hours later, and so on, thus flattening out the peak, and where conditions are extreme, to operate groups of mines on alternate days. The advantages from such procedure would be that the mines in operation would have continuous service and would not be subject to frequent shutdowns throughout the day, which has been found to be far more disastrous to the output than the alternative suggested.

Staggered System in West Virginia

The precedent for these suggestions was the arrangement made in the West Virginia coal fields a few months ago when a large unit broke down. In that case certain mines were operated in the morning and other mines in the afternoon.

The West Penn Power Co., of Pittsburgh, is suffering at the present time through a lack of capacity. In this case all non-war load has been thrown on night service. Even so, however, the demand is still in excess of the capacity by about 10 per cent. It has been arranged to cut off certain circuits for a period not exceeding 10 minutes and to rotate the cutoff so as to include all of the mines during the day. Thus, any one mine is liable to cutoff from one to three times per day for a period

of 10 minutes at each cutoff, or a total of 30 minutes during the day.

The result of the foregoing is to more or less systematize interruptions. The mines know when an interruption occurs that it is not going to last for more than 10 minutes. It is not possible to give any previous notice of an interruption, since the circuits are only taken off as the demand on the power plant exceeds a certain capacity, and that demand can never be predicted in advance. In this connection it has been found necessary to arrange for better coöperation between the telephone company, the central station and the mine, so that information concerning interruptions can be quickly transmitted.

There remains the radical alternative of night operation of mines. At the present time the West Penn Power Co. is taking on no new contracts unless the mining company is willing to operate at night. By referring to Fig. 32 it will be seen that after four o'clock in the afternoon and before seven in the morning the load curve is far within the generating capacity. Between these hours it is possible to take on additional load.

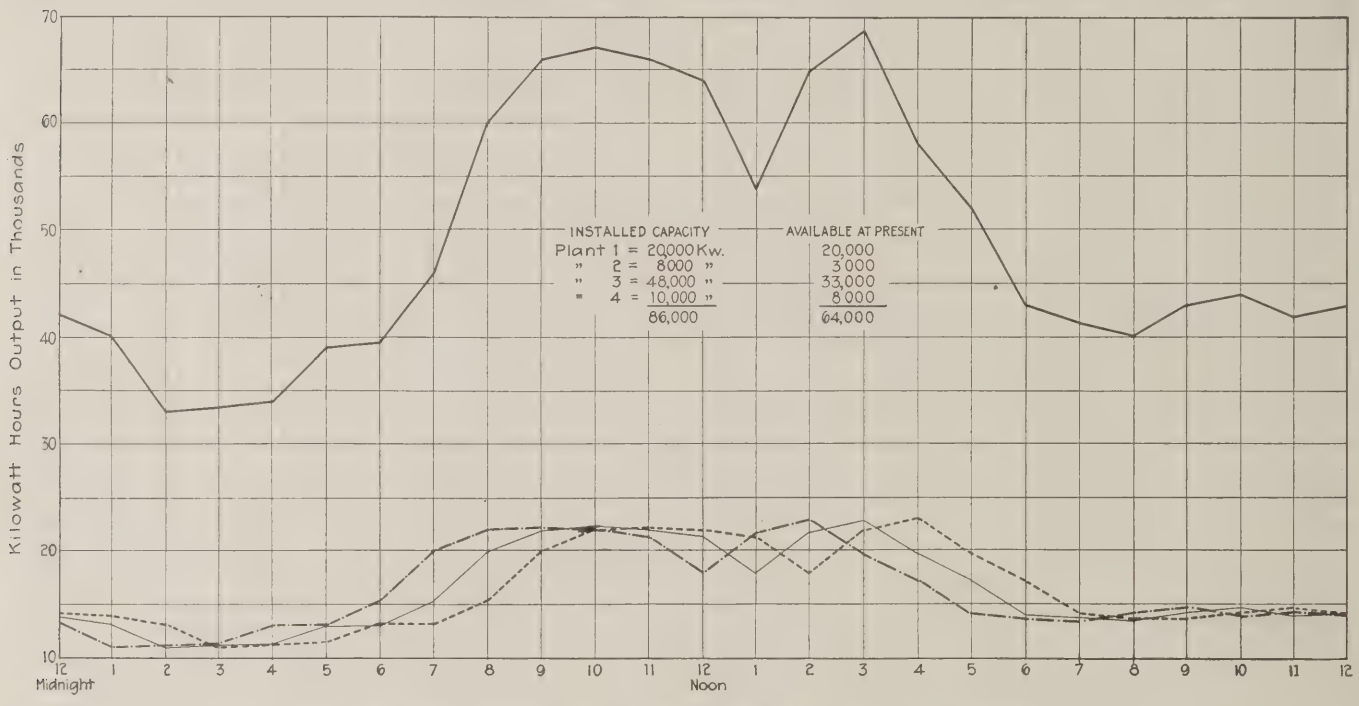
A few mines have accepted the alternative of operating at night, but they have not been on this service long enough to report results. However, it can be readily seen that the adoption of such an alternative may become inevitable, if production is to be maintained. Though the suggestion where made has been received with considerable disapproval, it may be noted that already many classes of war industries are accepting the inconvenience attendant upon night operation.

It is difficult to see why, if the steel mills, for instance, in normal times can satisfactorily operate on night shift, the mines cannot do the same, provided the necessity is sufficiently urgent. England, France and Germany in peace times have all established the precedent of a night shift. In a number of the mining centers of this country cutting machines and pumps have always been operated at night.

There are, however, on account of established precedent in this country, many difficulties to be overcome, and it is with a full knowledge of these difficulties, both physical and psychological, that I suggest that night operation may become inevitable in certain centers.

Not to do an injustice, it may be observed that many of the central stations serving mines have today ample capacity for their present as well as for additional load. Moreover, it is difficult to say that an operator with his own plant, the demand upon which is increasing, is in a particularly favorable position. The difficulty of expanding individual installations or of making new ones involve the same element of time, and the same considerations of high cost and skilled labor as those pertaining to central stations.

Today it will be far simpler from all angles to meet any large demand for additional power by increasing central station capacity than by the expansion of isolated plants, or the building of new isolated stations. Finally, it should be observed that through following some of the prescriptions elsewhere indicated, the operator himself can go a long way toward assisting the central station to take care of its load.



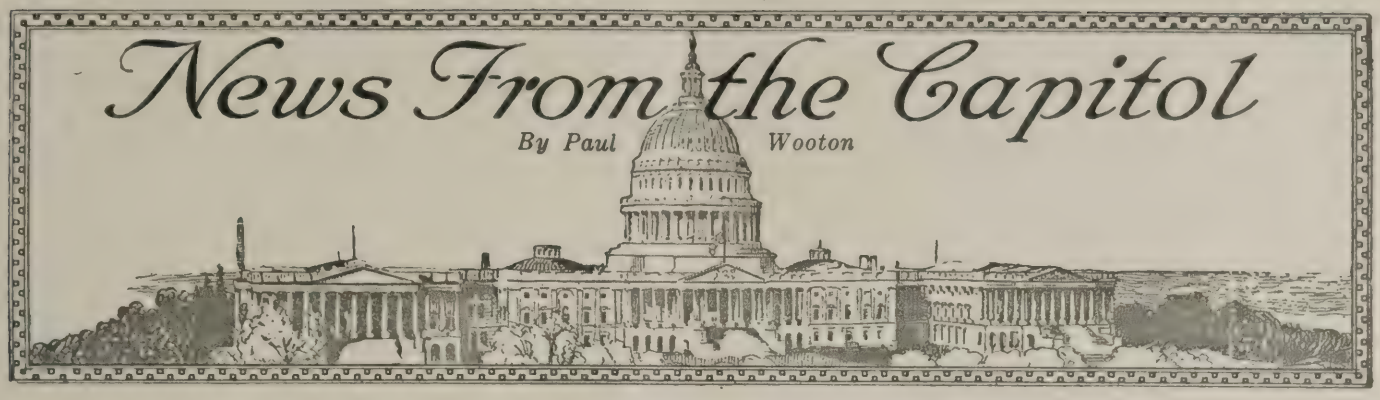


FIG. 32. LOAD CURVE OF A LARGE CENTRAL STATION COMPANY

Waste of Coal in Pumping Plants

It is estimated by the Chicago bureau of public efficiency that not less than 100,000 tons of coal are used annually in pumping water that is never used. This coal will keep 10,000 families warm during a cold winter. This waste could be put under control by the universal use of water meters. The Chicago water works is pumping about 260 gallons of water daily for every person in the city, which is about twice as much as most other American cities find ample for their needs. Pitometer experts have been at work searching for underground leaks which do not show on the surface of the streets. Several large leaks have been located and repaired.

Will Fuel Administration Cease to Function on Declaration of Peace?

Apparent proximity of peace has filled a great number of the men in important positions at the Fuel Administration with a great anxiety to return to their regular work. Some seem to think that the Fuel Administration will be the first of the big war agencies to go. While there is considerable demand on the part of consumers for the continuation of certain governmental regulations, it is regarded in some quarters that Congress would view unfavorably any proposal to continue the administration with the expiration of the present act.

The Railroad Administration, which will operate the railroads for twenty-one months at least after the signing of the peace treaty, will continue the zone system, it is said. Most officials at the Railroad Administration are said to be convinced that Government operation of railroads will continue indefinitely and plans are being made to perpetuate the zone system.

Such a decrease in consumption as may result from cessation of war work will be taken up, it is believed, by the normal industries, which have been curtailed. As a consequence, it is believed that the country can absorb the year's record-breaking output. It is also believed that the shipping situation will be such in the near future to permit of large coal exports.

Large Saving of Coal at Power Plants

Coal is being saved at the rate of 11,000,000 tons annually as a result of increased efficiency at power plants. While the Fuel Administration has returns to justify only an estimate of 7,000,000 tons saved, those in a position to know are certain that the higher figure is a conservative estimate.

For the efficient execution of the program of industrial conservation, under the plan developed, the engineers of the country have been mobilized through the professional societies and the operating engineers and firemen, and as a result there are today 1500 volunteer engineer specialists and power plant men organized by states, inspecting power plants, classifying them according to their operating efficiency, and aiding the work of rapid development. As a direct result of the operation of this plan, it is estimated that the total annual saving throughout the country will be about 25,000,000 tons of coal without reducing the output of the factories. Special printed material, instructing on the proper use of fuel, has been prepared by the United States Fuel Administration and may be obtained free of cost upon application.

The campaign has been organized in consultation with the State Administrators, the Bureau of Mines, and the Committee of Consulting Engineers of the Engineering Council, which represents the four national engineering societies. These four societies have contributed largely in supplying expert advice of engineering talent; special relations have been formed between the Fuel Administration and the National Association of Stationary Engineers, the International Brotherhood of Stationary Firemen and Oilers, the Laundry Owners' National Association, the Portland Cement Association and other national bodies who have given full coöperation to this plan.

Coke Workers Prove Efficient Railroaders

When the ranks of the men in the train service at the Republic yards of the Monongahela R.R. were invaded by influenza, it became impossible for the railroad to handle the cars to and from the coke ovens. Thereupon fifty coke workers, who had some knowledge of railroading, volunteered and cleared up the yard and saved a situation which threatened to stop coke production at Uniontown, Pennsylvania.

New Schedule of Anthracite Costs

After a period of intensive deliberation and discussion, the Fuel Administration has announced a new schedule of costs for the sizes of anthracite coal which comprise 70 per cent. of the total anthracite output. The actual increased cost per ton, because of labor, was found by engineers of the Fuel Administration to be 74c. This information was developed by taking the average number of men employed over a period of six months at each different kind of labor, in each mine, and developing therefrom the total increase in labor cost. This divided by the annual output of approximately 81,000,000 tons, gave the increased cost per ton. Dividing this in turn by the percentage of output over which the advance was spread, gave $1.05, the increase applied per ton.

While the new price schedule was not agreed upon finally until Nov. 6, it was made to apply to all coal mined on and after Nov. 1. Dr. Garfield, in announcing the increase in prices, emphasized the fact that approximately 60 per cent. of the season's supply was mined prior to Nov. 1, all of which will be sold at the former prices. "The full power of penalty under the Lever

Act," he said, "will be exercised to prevent the adding of any allowance to any coal shipped on or after Nov. 1 on which the increased wages were not paid."

The schedule takes care of no increased cost other than that of wages. The increase was based on a finding of the conference of National Labor Adjusting Agencies. That body found that wages in the anthracite region were below the standard paid in the bituminous industry and other comparable industries.

The increase was not applied to the remaining 30 per cent. of the output from the fact that, with any advance, bituminous coal would undersell these sizes and they would fail to move. Prices on sizes where no change was made are: Buckwheat, $3.40 to $4.15; rice, $2.90; barley, $2.65; screenings, $1.50.

The new prices make no change in the differential between the product of the large companies and of the individual operators. The new schedule is as follows:

White Ash Grade:		
Size	Operators	Price
Broken	Companies	$5.95
	Individuals	6.70
Egg	Companies	5.85
	Individuals	6.60
Stove	Companies	6.10
	Individuals	6.85
Nut	Companies	6.20
	Individuals	6.95
Pea	Companies	4.80
	Individuals	5.55
Red Ash Grade:		
Broken	Companies	6.15
	Individuals	6.90
Egg	Companies	5.45
	Individuals	6.20
Stove	Companies	6.30
	Individuals	7.05

Red Ash Grade—Continued:		
Size	Operators	Price
Nut	Companies	$6.30
	Individuals	7.05
Pea	Companies	4.90
	Individuals	5.65
Lykens Valley Grade:		
Broken	Companies	6.40
	Individuals	7.15
Egg	Companies	6.30
	Individuals	7.05
Stove	Companies	6.70
	Individuals	7.45
Nut	Companies	6.70
	Individuals	7.45
Pea	Companies	5.15
	Indviduals	5.90

For purposes of comparison, prices of certain of the sizes on the schedule which have been superseded are given: Broken—White Ash, $4.90; Red Ash, $5.10; Lykens Valley, $5.35. Egg—White Ash, $4.80; Red Ash, $5; Lykens Valley, $5.25. Stove—White Ash, $5.05; Red Ash, $5.25; Lykens Valley, $5.65. The foregoing are company prices. The differential for individuals is 75c. The new prices are subject to the graduated reductions for summer prices.

Record Production in West Virginia Fields

October production in the Pocahontas and Tug River fields exceeded by 40,000 tons the production in any previous month of the calendar year. This production was attained by 13,000 men, or more than was mined by twice that number in normal times. Owing to the shortage of coal for the Navy and for byproduct plants, this unusual record is particularly gratifying to James B. Neale, director of production for the Fuel Administration.

Fuel Administration Insists on Clean Coal

Nineteen mines in Pennsylvania and Alabama have been added to the list of mines ordered closed by the Fuel Administration on the ground that coal was improperly prepared. This brings a total of closure orders to 111. The Fuel Administration now is in a much better position to check its requirements as to clean coal.

In the week ended Nov. 2, 637 reports were received from the Administration's inspectors and 81 from state inspectors, making a total of 718. These reports showed that 545 mines were preparing coal properly and 161 improperly. Sixty-six carloads were rejected at tidewater; eleven cars were penalized and one was condemned at the mines. Up to date 80 inspectors have been appointed by the Administration and 124 by the railroads, while 106 state inspectors coöperated with the Administration in the work.

Plenty of Coal at Army Camps

Orders for 4,350,811 tons of coal and coke have been placed by the Raw Materials Division, of the War Departments, for use in army camps, posts, forts, proving grounds and hospitals throughout the United States for the fiscal year of 1919. This tonnage consists of 3,691,650 tons of bituminous coal, 642,728 tons of anthracite coal and 16,288 tons of coke. The winter supply of coal at the various camps is rapidly accumulating and considerably more coal is on hand now than at the same time last year. On July 1, 1918, the reserve was 190,000 tons. By Oct. 12, 1918, it had been raised to 530,308 tons. The fuel supply at posts most distant from coal fields is receiving particular attention.

Speeding Up Coke Industry

The seriousness of the coke situation has spurred the Fuel Administration to extraordinary efforts to increase the supply. Less than a week's supply is on hand at the 411 blast furnaces of the country.

Appointment of W. S. Blauvelt by the Fuel Administrator to look after coke production is bringing forth early results. Increases in coke production have been reported from several of the important districts. To assist Mr. Blauvelt, production managers are being appointed in the coke-making districts. A. H. Carpenter has been appointed for the Birmingham district and George B. Hughes for the Clinch valley and Southwestern Virginia district.

Advises Mixing of Anthracite Coal

A saving of at least 25 per cent. of the larger sizes of anthracite can be made by the combined use of buckwheat with the larger sizes, the Fuel Administration believes. Such a saving has been accomplished in Vermont. Owing to the scarcity of the larger sizes and the comparative abundance of buckwheat, the Fuel Administration is urging the mixing of the two by domestic users.

Garfield Resents Interference with Plans

A house-to-house coal survey, planned by the police department of Greater New York, brought forth the following letter from Dr. Garfield to Mayor Hylan:

"I am informed that the police department of Greater New York intends making a coal survey for the Fuel Administration beginning Nov. 7. I am advised by Delos W. Cooke, Federal Fuel Administrator for New York, that such survey was not requested by him and that it would be an interference with the best distribution of the available supply of coal allotted to New York State.

"I must respectfully but firmly request that this survey be not made, and that you prevent interference with the orderly distribution of coal in Greater New

York under orders issued under my authority by Mr. Cooke. He has full authority to act and understands that you will coöperate with him to any extent necessary. I must insist that Greater New York authorities be not permitted to interfere with the action of the United States Fuel Administration."

Austria Able to Meet Its Coal Needs

Austria will be able to supply its own coal needs for this winter, the Fuel Administration is advised, but there will be no surplus for exportation to Italy, it is said. Owing to lack of food, production from the Austrian mines recently has fallen to 50 per cent. of normal output. The return of men from the army in good physical condition and the improvement of the food supply of the country will make it possible, it is believed, to attain again the normal production, which is sufficient for domestic requirements.

Coal Exports in September

Exports of coal, as reported by the Department of Commerce for September, 1918, and the figures for September, 1917, as finally revised, are as follows:

	September, 1917	September, 1918
Anthracite, tons	448,124	442,714
Bituminous, tons	1,812,412	2,170,425
Exported to:		
Italy, tons	33,201	None
Canada, tons	1,553,196	1,820,244
Panama, tons	15,786	94,795
Mexico, tons	18,941	22,746
Cuba, tons	80,302	98,022
Other West Indies, tons	23,473	21,026
Argentina, tons	12,072	2,738
Brazil, tons	37,391	33 829
Chili, tons	None	32,712
Uruguay, tons	5,244	39,023
Other countries, tons	132,806	5,290
Coke, tons	88,071	132,553

Imports of coal during September, 1918, were entirely from Canada. They amounted to 111,196 tons, as compared with 112,705 tons imported from Canada in September of 1917.

Lake Shipments to End in November

Coal from western Pennsylvania will be made available for New England, New Jersey and New York after Nov. 15, when Lake shipments will be discontinued. On the same date, coal from District No. 8 will be made available for distribution in western Pennsylvania, in New York State west of Buffalo and in Canada.

Coal Loadings Show Increase Over 1917

From Jan. 1 to Oct. 26, 1918, a total of 724,978 more cars of coal were loaded than during the corresponding period of 1917. For the week ended Oct. 26, as compared with the corresponding week in 1917, loadings of coal cars were as follows:

	1918	1917
Total cars bituminous	192,529	187,939
Total cars anthracite	32,059	41,747
Total cars lignite	3,416	4,148
Grand total cars all coal	228,604	233,834

The Senate Committee on Manufactures will conduct another investigation of the coal situation. Senator Reed, the chairman of the committee, and Senator Lodge, a Republican member of the committee, are particularly anxious to have another hearing following the line of the hearing conducted by the Manufactures Committee some months ago.

To Improve Power Conditions At Mines

Steps have been taken by the Fuel Administration to improve power conditions at coal mines. In each production district a power engineer is to be named. He is to head a committee of three and will be charged with the duty of improving power conditions.

Loads on power companies are growing rapidly, the Fuel Administration states, and the tendency is to take all the load offered so that in many cases there is no reserve, while the extension of work by agencies like the Ordnance Department, for example, foreshadows further drains on stations supplying mines.

"The central stations in nearly every coal-producing center of the country are overloaded," says a letter from the Fuel Administration to its production managers, "and eliminating the question of power demand for additional mines, the rate of increase of power demand of mines already in operation is rapidly increasing to a point where the stations in many cases will be unable to carry their load. We believe that by coöperation along these lines great service can be rendered."

Legal Department

WYOMING COMPENSATION ACT VALID — The Workmen's Compensation Act of Wyoming is constitutional and valid in all of its provisions. (Zancanelli vs. Central Coal and Coke Co., 173 Pacific Reporter, 981.)

CONTRIBUTORY NEGLIGENCE OF MINE DRIVER—Plaintiff, in collecting loaded cars in a Missouri mine, drove a mule attached to a car along an entry. Without stopping the mule, he stepped off backwards, without taking heed as to his location with a view to avoiding injury because of any narrowness of the entry at that particular point. He might have readily stepped off in the clear at a nearby point, but, alighting at a corner of a room neck, his back struck a hump or ridge in the side of the entry, unbalancing him and causing him severe injury through being crushed between the car and the side of the entry. Under these circumstances, it is held by the Kansas City Court of Appeals in the case of Maize vs. Big Creek Coal Co., 203 Southwestern Reporter, 633, that plaintiff was guilty of such contributory negligence as debars him from recovering damages against defendant, his employer.

LEASING A WARD'S LAND—A lease of a ward's real estate for mining or other purposes is not valid beyond the period of his disability, and the legislature of a state cannot validate leases beyond that time. This is the gist of an important decision handed down by the Kentucky Court of Appeals in the case of Lawrence E. Tierney Coal Co. vs. Smith's Guardian, 203 Southwestern Reporter, 731. A statute enacted at the 1916 session of the Kentucky legislature declared that the guardian of a minor or of a person of unsound mind might lease the ward's real estate "for the purpose of mining and removing all or part of the coal, oil, gas and any or all other mineral or mineral substances and products therein. . . . Such lease may be for such length of time as the guardian . . . may approve, without being limited to the time at which the disability of such infant or person of unsound mind may be removed." This statute, the court holds, is unconstitutional as an interference with the ward's enjoyment of his property rights on becoming legally competent to transact his own affairs. Speaking of the rights of a ward, the court said: "It is, of course, true that he will derive from it each year a valuable income, but this falls far short of the exclusive dominion that every adult citizen of sound mind desires and should have the high privilege of exercising over his own property."

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The prospect of peace that brightened the end of last week had also the effect of making manufacturers less clamorous for coal. All of a sudden it seemed as if the fears of coal shortage were ended except in so far as anthracite was concerned. It seems certain, however, that a readjustment will soon take place, and the industries now restricted will come into the market and make their claim for full supplies of fuel. It cannot be that the frantic cry for coal will be followed by a surplus which will make the mine workers mark time even in the winter, when the demand is usually at its briskest.

However, no one can feel much confidence in the consuming public. When it cannot get coal it is ready almost to start a revolution to obtain it, and then, as soon as a slight letup in demand arrives, the average consumer is willing to wait indefinitely in order to force prices down. If it is criminal to raise prices in a public extremity it is equally criminal to depress them by concerted abstention from purchase. The buyer has duties as well as the seller. He has no more right to conspire to secure an unfair price than has the seller a right to conspire for the same reason. If it is not a conspiracy, but overstocking, then the buyer has been storing to excess and so has been acting equally unpatriotically.

MARKET ANSWERS THOSE WHO SEEK INCREASE

It may be said, however, that the condition of the market will do a great deal to make the mine workers of the bituminous region satisfied with their generous wages. They have been clamoring to Fuel Director Garfield and even to the president of the United States that wages were too low and that the profits of the operators would permit of a readjustment. If the industry is put fairly on a competitive basis and if the mines which ought not to be in operation are closed down by the decline in price it will no longer be possible for the mine workers to make complaint and the last will be heard of their demands, at least for a while.

The wage increase in the anthracite region which aroused the jealousy of the bituminous mine workers has not satisfied the anthracite men. The officials of the union claim that the faith of the board which determined the wage has been broken. It was clearly understood, they say, that the increase was to date from Oct. 1, whereas now the award is made, Nov. 1 is the date fixed, and the mine workers lose what it had been planned that the operators should pay them out of pocket, for only the wage could be retroactive.

The operators could not make a retroactive charge on coal already sold and in any event they have to write off expenditures between Nov. 1 and the date of Dr. Garfield's order of readjustment of prices. As the average increase per month to each worker is roughly $25 it is easy to see that the matter at issue was about $3,827,000 for the month of October only. The miners, however, would not feel satisfied even had Oct. 1 been set as the date for the adjustment. Some would set it back to a period some 10 months ago, to a point immediately following a conference which occurred early this year.

It is said that the anthracite mines are getting more men because of the increased wage. Probably the decreased probability of steady work in munitions plants has something to do with their return. The end of overtime and Sunday work has probably had some influence, as also the return of cold weather. This return of the working force should assist greatly in easing the situation in the anthracite region, now recovering from the ill-effects of the influenza.

Peace celebrations are proving severely restrictive of production even in those areas where demand continues at a maximum and is sure to continue even now that hostilities have come to an end, as we hope, for ever. Manager of Production W. L. Byers in the Connellsville region has been making personal appeals for more coke to the working forces of that region.

The appeal that the mine workers "work as they (the soldiers) fight" has been addressed to all the coke workers, especially to the Czecho-Slovaks. The mining and coke-yard forces, he has dubbed "Our Coal and Coke Army." The armistice, however, makes it necessary to write the matter differently, for we will have to work when the soldiers don't fight, for having won the war we must now make the peace secure.

RABBITS, CELEBRATIONS AND THE INFLUENZA

The opening of the rabbit season has made some mines in Pennsylvania close down. Coming with All Saints Day it was hard to prevent a general abstention from work. Especially was this the case in Butler County. Rabbits, celebrations and influenza combined to make a three-fold disturbance with which the production managers found themselves utterly unable to cope.

An excellent spirit has been shown by the men of Davy in the Pocahontas district, where the Superior Pocahontas Coal Co. is operating, George Wolfe being manager. Not only the miners are willing to help by doing more than a day's work, but the store and office employees and a clerk employed by the Norfolk & Western Ry. and one employed by the McDowell County Telephone Co. have gone to the mines to work after their regular day's work is done. They pledged themselves to mine two gondolas a week from the Cletus mine of the Superior Pocahontas Coal Co. They have been going to the mine every Wednesday and Saturday and have been returning home at midnight. The roster of patriotic men includes the mine foreman, two motormen, two brakemen, a mine engineer, a cashier, a bookkeeper, a scrip clerk, four store clerks and the two clerks already mentioned as not in the regular employ of the Superior Pocahontas Coal Co.

The influenza has been particularly grievous in the Fairmont region, especially in Barbour County, which lies on both sides of the Tygart River. The mines of the Winifrede Coal Co., just above Charleston, W. Va., have been put virtually out of commission by the influenza. The company had to erect a temporary hospital for the care of the patients. The influenza epidemic is raging also at Olcott in the Kanawha district. The New River district, which for a long time escaped the influenza epidemic, finally received it in its full strength. It almost closed down the operations of the New River Co. and those of the McKell Coal and Coke Co.

British Columbia Still Has Difficulties

British Columbia miners in the Fernie-Michel district of Crowsnest Pass are still working, but they have apparently decided that the conditions they have imposed on the operating company shall not be subject to the inquiry purposed by a royal commission. The men insist that the single shift must be permanent and they are strongly opposed to any investigation to determine the danger or safety of any other manner of operation. Knowing that any royal commission, which was ex-parte, would be regarded as unfair and invalid they have delayed appointing a representative to act for them on the commission. Consequently the commission cannot meet.

The mine workers declare that under Provincial Regulations which prohibit public gatherings as a step toward

stamping out influenza they cannot meet to make the selection of a representative. Strange to say, despite these Provincial Regulations they have been able to protest most vigorously against the no-strike order of the Dominion government. Apparently there is no risk of influenza when protesting against the government, but great danger when meeting to elect a representative for a royal commission.

The protest runs as follows:

"Whereas, the new order-in-council taking away from the workers in Canada the right to strike, although introduced as a war measure, will be made permanent if it can be made effective, therefore, be it resolved that the Gladstone local union 2314, United Mine Workers of America, register its solemn protest against such legislation, that a committee be appointed to interview Dr. Bennett, the federal representative of this district, and urge him to immediately wire Premier Borden a strong objection to the order-in-council, and that a copy be immediately sent to the trades and labor congress of Canada together with an expression of disapproval that that body has shown itself unworthy of confidence by its neglect to take drastic action in the face of the publication of such an autocratic order by the cabinet of Canada."

The circular sent out with this resolution to all organized labor bodies concludes by saying: "If we submit without protest to the passing of such an order, no labor organization will be necessary because we shall revert to abject slavery."

It was understood when the Fernie miners returned to work that all the workings except those rightly regarded as being development places should be placed on a single shift. The determination of this matter was naturally difficult. J. O. Jones, advisor to W. H. Armstrong, director of coal-mine operations in District No. 18, and Robert Livett, international representative of the United Mine Workers of America, accompanied representatives of the management of the colliery on an inspection trip of the mines as soon as the men voted to go back to work. They visited all the places alleged by the company to be under development. Over 30 of these development places occasioned dispute, but finally almost all of them were satisfactorily classified. Those which remained unclassified are to be referred to Mr. Armstrong for final decision.

Unique Mine Portal

By Ralph W. Mayer
Connellsville, Penn.

The Beaver Mine is located a few miles down the Monongahela River from Brownsville, Penn. The coal it produces is all loaded on barges and shipped by water. The hill in which the coal bed lies rises rather abruptly from the river. The narrow bench between the base of the hill and the stream is occupied by the double-track line of the Pennsylvania R.R.'s Monongahela Division. The coal seam lies on a level with the railroad track, or lower. All the coal has to cross the railroad tracks in order to reach the barges on the river.

To build a high tipple from the mine across the railroad tracks to the river would have been expensive. This expense would have been unwarranted considering the small acreage that the mine will develop. A cheaper method of developing the mine had therefore to be used. A tunnel was driven from the river, under the railroad, into the hillside, striking the coal bed.

This tunnel was lined with thick walls of concrete well back into the coal. The portal, or entrance, is below high-water mark. This was necessary in order to get it under the railroad track. High water on the river would thus completely fill the mine. To prevent this a water-tight door was placed at the portal, or entrance, and another well inside the tunnel.

Around the entire circumference of the portal 1½-in. bolts were solidly embedded in the concrete. These were spaced about two ft. apart and were provided with suitable nuts. The door which closes the mouth of the tunnel has holes around its edges, corresponding to the position of the bolts embedded in the concrete. Four-inch washers are placed on the bolts on the outer side of the door, to spread the pressure of the nuts over a larger surface. This holds the door firmly against the concrete lining forming the mouth of the tunnel. All the seams or cracks around the edge of the door and between it and the concrete are caulked with oakum. A coating of pitch over this and over all exposed nail heads makes the door practically water-tight. The door is made from 2 x 12-in. planks placed horizontally with surfaced, tongued and grooved 1-in. boards nailed

UNIQUE PORTAL AT BEAVER RUN MINE

diagonally across them, on both sides. The second, or inside, door of the tunnel is made and fastened in the same manner. The entire inner surface of the tunnel is lined with concrete. This includes the floor under the track. When it is desired to place the door in position, a short length of track at the end of the tunnel is removed. No ballast is placed under this portion of the track next to the concrete, thus allowing the end of the concrete lining to be clear for about 2 ft. below the floor of the tunnel. The door therefore comes into contact with the concrete below the track. This seals the entrance, or portal, around the circumference.

A short incline runs from the mouth of the mine to an inexpensive tipple set on piling and from which coal is loaded onto barges. This tipple is made simple and inexpensive, so that it can be readily removed.

Coal Deposits of the World

The distribution of the coal deposits of the world tabulated by countries, is as follows:

	Short Tons		Short Tons
United States—including Alaska	4,231,352,000,000	Russia in Europe	66,255,000,000
Canada	1,360,535,000,000	Union of South Africa	61,949,000,000
China	1,097,436,000,000	Austria	59,387,000,000
Germany	466,665,000,000	Colombia	29,762,000,000
Great Britain and Ireland	208,922,000,000	Indo-China	22,048,000,000
Siberia	191,667,000,000	France	19,382,000,000
Australia	182,510,000,000	Other Countries	69,369,500,000
India	87,083,000,000	Total	8,154,322,500,000

Shall We Traffic with Germany?

WHEN the question is asked "Shall the Allies accept goods of Germany after the war?" the first impulse is to say "No"; for we are all apt to regard the purchasing of goods as a favor to be denied those who have offended us. Yet it is true that those who sell us goods do us a service. The man who sells us labor and materials is helping us by that act as much as we are helping him by making payment for them. We are bartering one kind of goods for another unless, indeed, one party is in debt to the other; and then the goods are not really exchanged but given in payment of the debt.

Germany will be the party in debt if she is compelled to pay reparation in accord with the evil she has done. She will be so much in debt that she will not be able off hand to pay what she owes. She will not have the monetary resources to meet her obligations with the savings of the past. She will have to earn the payment. She must mortgage the future. In a sense the world will be obliged to garnishee her wages.

But if she is to have work and earnings, some one must employ her, some one must buy her goods. When a man has been allowed to run up a big bill at the company store, out and beyond all reason, the manager of the company desiring to see it paid is quite apt to keep him at work regardless of his character. If the man is discharged, and worse yet, if he is blacklisted, there is no hope for payment; for what a man does not earn cannot be garnisheed. If we will not take spoil of Germany, year by year, how can she pay us the tribute that will settle the bills she has so lightly incurred?

No nation can do a business indefinitely that is all outgo. We cannot ship goods without taking goods in exchange, for no nation has the money to buy indefinitely, unless she produces gold and silver; and if she does, these metals, coined though they may be, are in themselves a form of goods. Germany cannot send us or the Allies the large amount of money due unless some one is willing to buy from her. We must therefore take our choice between reparation or ostracism, or impose both only in a degree.

If the Allies insist on the payment of the debt they must accept nearly all of it in goods, delivered over a period of years. They may regulate the nature and rate of the payment somewhat, but, in goods, payment must and will be made. Only by cancelling the debt or wiping out most of the account can we put up the bars resolutely against Germany.

The proposition revives memories of the discussion relative to prison labor. Some would keep the product of the prison from the market. As it is now, in general, we let the well-intentioned go without recompense and even make the well-intentioned part of the citizenry pay for the keep of the prisoner. He pays back nothing to society for what he has taken. There is no reparation, but there is punishment. The prisoner suffers and usually is rendered vengeful, and the public is in no way advantaged. As it is when we exclude prison goods so it will be if we wholly exclude German goods. The nations will have to repair what Germany has destroyed. Better it would be to take a few of Germany's goods till the bill is paid. We would keep them without further payment, and thus we would square up the indebtedness that is owing to us and our Allies.

Redeeming the French Coal Fields

THE newspapers have been persistent in playing up the town of Lens as the one coal-producing spot of France. The correspondents seemed to be obsessed with the idea that if the Allies had Lens, France was a coal producer, or might eventually become a producer; if the Germans had it, France had no coal. Like most newspaper tales, this does not represent the truth.

Coal is pretty well sprinkled over France. True, the deposits are not large, but they are worked quite generally. The largest body of coals is in the Départements du Nord and Pas-de-Calais. This is the deposit that the Germans invaded. They probably rendered much of it unworkable, for it is likely that much which they did not take they menaced or destroyed by their shells. Where, however, they did not actually take possession the destruction could not be complete.

It may be many months, even years, before the mines in the Département du Nord will be operable, and many around Lens in the Département of Pas-de-Calais will be equally slow in being brought to the point of production. Before the war the output of the mines around Lens was put at thirteen millions of tons, and the whole field, Nord and Pas-de-Calais, totalled thirty-seven millions, the whole output of France being forty-four millions.

Thus this one northern field produced about 70 per cent. of the coal and the region around Lens about 30 per cent. The other fields were the Loire, Bourgogne with Nivernais, Gard, Tarn with Aveyron, Boulonnais, Auvergne, Alpes, Hérault, Vosges, and the "West."

These many small fields have been greatly stimulated by the war. Whereas forty-four millions was the output of the whole country before the war started, in October of last year the production was at a rate equalling nearly thirty-seven million tons, or nearly 80 per cent. of normal. With peace established, with a return of the mine workers from the battling lines, and with the demand for coal at the 1914 figure, it is likely France could supply herself with coal without assistance from Lens and without any outside help other than such as she had always accepted.

But France has always used about twenty-two million tons of imported coal, and after the war the demand

will continue for a while to be abnormal. That demand may be as large or larger than it is today. It is doubtful whether Great Britain will be able to supply it all, for the demands of its own trade will be quite large. Every effort will be made to retain the French as Great Britain's customers, and to that end England will go short herself rather than lose her prestige in France.

All But the Squeals

IT IS said that every part of the hog, except the squeal, is used by the packer. That cannot be said of coal. We demand that the bone be left in the mine and the pyrite also. There are clays which would serve for the making of brick. There are bituminous shales which could perhaps be profitably worked for their oil. But we leave these in the mine and tumble the roof upon them. Some day we may save all these byproducts of mining. We know there is something combustible in shale when we note how hotly a rock dump without any coal in it will burn. There seems to be no fuel present, but the pile is nevertheless inexplicably hard to extinguish.

Should we some day pay the miner by the day instead of by the ton, we shall be able to extract the coal even cheaper than we do today; and if we are willing to take all that goes with it, we shall find that we can get the other minerals—bituminous shale, bone coal, sulphur, clay and brick shale—for little additional cost. As it is, we operate our mines on the piece basis and pay no more for clean coal than we would have to pay if we took all that comes; so we demand that the coal shall be clean. If we were buying only the meat of pork, and told the farmer we wanted the bones also, he would try to give them to us at meat cost; and if he was as illadvised as the miner, he would hold out till he got it accomplished, and he would in consequence sell no bones at all at any price. If a contract had been made of this kind with the farmer, the meat business would never have reached its present stage. Let us think seriously of the time when we shall use every part of the mineral deposit—all except the squeals.

Are These Sudden Scruples Inspired By German Statements?

BEFORE the war we sent our goods to Great Britain without tax, but we taxed all that Great Britain sent us. Then we tried to make reciprocity arrangements with other countries which had tariff walls against us. We sought in these to give them a lower tariff in return for lower tariffs in those countries. Thus, though Great Britain admitted our goods free we tried to arrange matters so that Great Britain would in trading with us be at a disadvantage as compared with other countries, and in trading with other countries would be at a disadvantage as compared with us.

We did not think for one moment it would make Great Britain bitter. We did not believe it would be a fosterer of wars. We trusted her breadth of view to prevent any such thing. No! that does not adequately express it. We could not conceive that any such action on our part would make a criminal nation out of Great Britain, of whom we believed instinctively almost everything good, though we were somewhat chary of stating it. We knew what we might do financially against her could never make her take up the sword against us.

What has made such a change that we are told today on excellent authority that "the experiences of the past among nations have taught us that the attempt by one nation to punish another by exclusive and discriminatory trade agreements has been a prolific breeder of that kind of antagonism which often results in war, and that if a permanent peace is to be established among nations every obstacle that has stood in the way of international friendship should be cast aside?" What has made this change in viewpoint? Is it not Germany—that Germany that bleats like a lamb yet has the horns and tactics of a goat?

Before the war we endeavored, in the traffic of some materials, to make arrangements as hard and painful for Great Britain as those we are now discussing for Germany. We tried to do to Great Britain, seeing that she was generous and easy, what we are trying to do today to Germany because she is so vicious. We did not think it dangerous then. It wasn't dangerous. It is dangerous only with Germany because of a certain inherent satanic quality of the wild tribes beyond the Rhine.

Surely no moral scruples should restrain us—scruples to which we have been strangers hitherto. If we so desire, we have a perfect moral right to keep Germany from our market and admit the Allies thereto. If we have not, then we are convicted of years, generations even, of a certain moral obliquity. Germany surely realizes, deep in what should be a heart, that she richly deserves punishment.

If we schemed to make Great Britain pay the penalty of discrimination without desert on her part and for her very virtue, surely we should not hesitate to make Germany pay it in view of the blackness of her many infamies. Everyone is aware of the maudlin disposition to punish a peccadillo with fine and imprisonment and to rebuke murder with a mere slap on the wrist or a harsh look. The plans of those who would spare Germany from exclusion from our markets out of mercy and would reserve that punishment for some other country are amazing.

Are we looking for a country more infamous than Germany before instituting this penalty, or are we planning to visit that punishment on some better country who may anger us not by murder but by failing to invite us to participate in some portion of its trade or by holding out from us some trifling privilege of transportation—a port leave, for instance, or the right to use a canal, a channel or a water power? True, that would be a preventive and not a punitive action; but it is providing a bigger punishment for a peccadillo than is provided for a crime of outstanding heinousness. It is making a mountain out of a molehill, and, worse yet, a molehill out of a mountain.

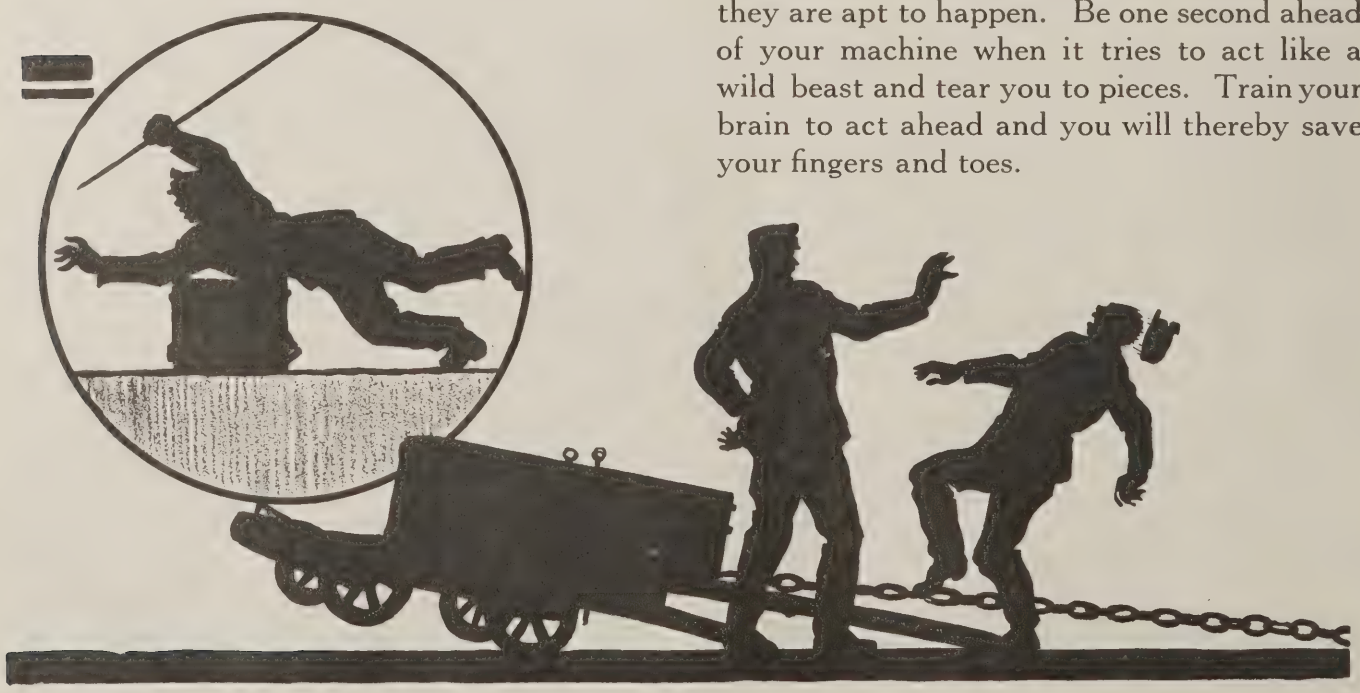
The question of whether we will ostracize Germany from our markets is not so much one of morals as of expediency. It is likely that confronted with difficulties in reparation we and our allies will be disposed to let Germany trade a little with us and that we shall remember that if Germany's trade is so barriered that she can do business only with neutrals we shall find her competition with us made the fiercer by that restriction.

MOVING MINING MACHINERY

Safety Letter from a Large Company to Its Men:

A mining machine can at times act almost like a wild beast in tearing or lacerating hands and feet. It is most important that men operating machines should learn to think and thus anticipate what may be the next movement of their machine.

A lion trainer in a cage full of roaring lions is perfectly safe just because he knows exactly what each lion is going to do the next instant and knows it one instant before the lion can do it. He has a trained mind which can anticipate the lion's next act, and he has trained himself so that he knows what he must do to protect himself before the lion is able to act.



Mining machine men must especially look out for their own safety by knowing how accidents have happened and by understanding beforehand what they must do to protect themselves. They must train their brains to keep one second ahead of their work.

In this company nine men have this year broken ribs by falling over the frame of the machine when the bar they were using to

skid the machine slipped. Four men have this year had arms or feet caught by the sudden tilting of the machine as it was unloaded. Three men, while walking or crawling alongside of the machine, have had hands or feet injured, either by slipping under it or by having it upset and fall on them.

Your life is the most important life that has ever been lived—so far as you are concerned. You know bars will slip when skidding your machine. Be prepared for them to slip. You know machines will tilt up when unloading them. You know machines are apt to get off the track—but why tell you these things which you already know? The big thing is for you to anticipate the time when they are apt to happen. Be one second ahead of your machine when it tries to act like a wild beast and tear you to pieces. Train your brain to act ahead and you will thereby save your fingers and toes.

DISCUSSION BY READERS

Iron vs. Wood Mine Cars

Letter No. 2—The inquiry pertaining to the choice between iron and wood mine cars, which appeared in *Coal Age*, Sept. 26, p. 615, was doubtless read with interest by many. This is a question that is often discussed, in the different coal fields, where there are always strong advocates of both of these types of cars. There is also a multitude of men who are wedded to a composite or combination steel-and-wood car.

Many different details, however, enter into and decide the choice of a mine car, as to the material to be employed in its construction. For example, a mine located in close proximity to good oak timber that will enable a company to build its own car bodies, ready for mounting on a high-grade truck, which together with the body irons can be obtained at a reasonable cost at a nearby factory, will generally decide the choice in favor of wooden cars.

In such a case, the present high price of steel and the difficulty of obtaining it make the use of wood for the purpose more than ever desirable. Moreover, a wood car that will carry as much coal as an all-steel or composite car will cost less and be less subject to the corrosive effect of the acid mine waters, which often makes the wood car desirable.

Combined Iron and Wood Cars Give the Greatest Amount of Satisfaction

Where conditions are favorable, however, the consensus of opinion seems to favor a combination of these materials or a composite type of car, having steel sides and ends and wood bottoms. The most serious objection to an all-steel car is the fact that where a wreck occurs in the mine and the cars are piled up, one or more of them will be banged so badly as to make their repair difficult and cost almost as much as to build a new car.

It is true that when a wood car is built properly it is frequently a massive affair and cumbersome. Also, while a wood car is durable, it does not have the same flexibility as a part steel and part wood car and, for the same outside dimensions, its capacity is appreciably less than that of a steel car. In my experience, a combination steel-and-wood car is more easily dumped, especially when a thin piece of steel is laid over the plank in the bottom of the car, as the coal then slides more readily from the car.

A minor point, but one that is still worthy of consideration, is the fact that the center of gravity of an all-steel or combination steel-and-wood car is relatively lower than in a wood car, and less racking of the car and wear and tear of the running gear results, and there is less coal spilt along the roadway. Where the cars are equipped with plain-bearing wheels, the jerk of the locomotive, in starting a trip, is more severe when the center of gravity of the car is higher above the tracks. This matter is not so vital, however, where the cars are equipped with roller bearing wheels, as the trip is then started with less jerking and bumping.

Everything considered, my choice favors a composite car, strongly braced and equipped with roller-bearing wheels. The question of the extra weight of all-steel cars is of more importance where heavy grades occur on the haulage road or the cars must be hoisted in a shaft or slope.

OPERATOR.

Philadelphia, Penn.

Mining Equipment

Letter No. 8—Speaking of mining equipment, the repair of broken parts in and around a mine has always been a source of trouble to every superintendent and foreman. A vital piece in a machine that is in constant use suddenly breaks. The nearest foundry is several miles away. Unless the old part can be patched or a new part secured immediately, a shutdown will result. The case is urgent, the need pressing; what is to be done?

Fortunate, indeed, is it if the superintendent has learned of the general use of the electric arc-welding machine, which has followed so closely on the heels of all modern equipment. Some time since, he heard that good welding could be done by this machine; and, efficient man that he was, he secured one in anticipation of just what has now happened.

The new device has been in use in the shop long enough to enable a workman to be thoroughly acquainted with its use. Word is telephoned to the shop and, in less than an hour, the broken part is mended and the disabled machine is again in operation and the dreaded shutdown of the mine avoided. In the meantime, a new part is ordered to be sent from the factory and held in readiness to replace the mended part should it give way again.

Saving Effected by Arc-Welding Process

The importance of the arc-welding machine, in such work, can scarcely be overestimated. The average railroad machine shop, a few years ago, was wasting thousands and thousands of dollars, because they did not know that broken parts of steel or iron could be welded and made fit for service again. Few had faith in the welding process. Locomotives were laid up for weeks while being fitted with now boiler tubes, and a breakdown on the road meant a staggering loss to the company.

Many of our mines, today, are throwing away thousands and thousands of dollars, because of the same ignorance or lack of faith in the efficiency of the welding system. Many mine operators, superintendents and foremen have yet to learn that butt-welded joints can be made almost as strong as the original metal, by

welding with or without reinforcement. Where reinforcement of the metal is possible, however. the original strength of the metal can be realized. Experience shows that much stronger and more perfect joints can be made by the electric process than by the usual gas method of welding, and the cost will be but a fraction of that incurred by the use of gas for this purpose.

No Preheating Required in Electric Welding

An important feature in welding with electricity is that no preheating of the parts is necessary in making an ordinary weld by the electric process; but the use of gas for that purpose generally requires the previous heating of the parts so that the filling metal will not be chilled, which would impair the strength of the weld. In the electric process, the material to be welded is the positive terminal and, consequently, the hottest, which insures perfect fusion, as the heat generated warms the material and prevents the chilling of the filling electrode or material.

The welding equipment is very simple in construction and has no complicated parts that require expert knowledge to keep them in serviceable condition The device has been so improved and protected that it is nearly foolproof and can hardly be misused. The equipment consists of a suitable motor with a low-voltage generator, which is protected against overloads caused by heavy rushes of current at the time the arc is struck.

Because of the low voltage, it is necessary to make contact and then break away when drawing the arc. By "making contact," I mean that the metallic or graphite electrodes must touch the metal that is to be welded, in order for the flow of current to start. It is at the time of drawing the arc that heavy overloads occur. Then, if the right kind of attachments is not employed, the generator will likely be put out of commission. Cast iron, steel and cast steel are the most common materials that can be handled to the best advantage by the electric-arc system.

Skill of the Welder an Important Fartor

The average worker who has been properly instructed in the process of mending broken parts is fast being recognized as one of the most useful men around a plant, since it is his skill that will often keep the plant going when otherwise it would have to close down to await repairs. The fact is generally accepted that the enormous saving, which has been proven in railroad and electric railway shops, can be exceeded by the more general use of welders at the mine. This is because of the fact that the location of the latter is generally inaccessible to the sources of supply and often void of good shipping facilities.

It should be stated, here, that when welding smaller pieces the metallic electrodes are used and the amount of current varies from 50 to 200 amp., depending on the bulk of the material or size of parts to be welded. Where heavier parts are to be welded, however, carbon or graphite electrodes are used, and the current varies from 300 to 600 amp. These varying degrees of current are obtained by the cutting in or out of the resistance.

Good welding can be done by the use of a sufficient number of cast-iron resistance grids; but that method is wasteful, because much of the electrical energy is then dissipated in the form of heat, by reason of the resistance grids. The use of the regular electric arc-welding equipment is much more economical where the current is drawn from the main power line. In fact, the use of this welding outfit has proved so economical that it is hard to understand how the mining industry has overlooked its possibilities for so long a time.

What needs to be safeguarded against, however, is the lack of skill of the worker. A poor welder can ruin a vast quantity of material, while an efficient welder is worth his weight in gold, by reason of the economies he will effect. All reliable vendors of electric arc-welding equipment are ready to furnish the services of a skilled demonstrator, at a nominal charge. In ten days' or two weeks' time such a one can thoroughly train a bright man in the successful operation of the equipment.

Ventilating a Gassy Slope Mine

Letter No. 6—Being a coal miner of 33 years' experience in the mining of coal, both in Scotland and in this country, and being familiar with the varied methods of working coal seams and the essential requirements in order to secure the best results in production, I am not surprised at the frank manner in which "Mine Foreman" seeks information, through the columns of *Coal Age*, in regard to the best method of ventilating a slope mine that he is about to open in a seam having a general dip of 6 per cent. and generating large quantities of gas, as stated in the issue of July 25, p. 191.

In the haste to realize on the investment and secure quickly a large output of coal, very little thought is often given to the essential features of the ventilation that will be required in the future development of the mine. These requirements relate to the number, kind and size of openings; kind and size of ventilating fan; and the volume of air that must be circulated in the mine to comply with the mining law of the state and give to each man and beast employed in the mine the specified quantity of air. The circulation must, at the same time, be sufficient to dilute, render harmless and drive away the gases that would otherwise accumulate in the workings. Such are the important features that must be considered in the prospective ventilation of a mine.

Requirement of the Colorado Mine Law

While the driving of three main slopes on the full dip of the seam, as suggested in the reply to this inquiry on the same page, is a proper answer and will apply to the opening of such a mine in most states and districts, it does not meet the requirements of the coal-mining laws of Colorado, where the new law provides for an independent opening called a manway or travelingway, which must be separated from the main haulage opening by not less than 300 ft. of natural strata, except as otherwise permitted by the written consent of the chief coal mine inspector.

The suggestion of R. W. Lightburn, in his excellent letter on the subject, Aug. 22, p. 373, more nearly expresses my idea. Mr. Lightburn states that this mine should be opened by five headings driven on the dip of the seam, adding that two of these should be made intake airways and haulage roads, while the remaining

three entries would serve as return airways. But, inasmuch as this arrangement would necessitate men going to and from their work, either traveling the haulage road or one of the return airways, I am obliged to differ with him somewhat, in respect to this plan.

In my opinion, it is not safe for men or animals to be obliged to travel a main haulage road; neither do I consider it a healthy proposition for miners to be obliged to use the return airway in order to reach their working places. The plan I would propose for opening this mine consists in driving not less than five slopes on the full dip of the seam. Indeed, better results will often be obtained by employing seven openings, which will provide ample facilities for ventilation, especially in a mine generating much gas. I consider that good ventilation is the most essential feature in any mine, whether the seam is generating gas or otherwise. In the matter of securing the economical production of coal, let me say, the ventilation of a mine is second only to that of hauling, as miners will not work in a poorly ventilated place any more than they will tolerate bad haulage conditions and a limited car supply.

Allow me, therefore, to advise "Mine Foreman," in opening his mine, to adopt a method that will provide ample facilities for ventilation. After the five main slope openings have reached a sufficient depth, cross-entries or levels should be turned to the right and left, on the triple-entry system. If this seam is generating gas in large quantities, the cross-entries should be driven to the boundary, while butt headings are driven off these on the full pitch of the seam.

Retreating Panel System of Working

I would suggest driving the cross-entries or levels at distances of 100 yd. apart and the butt headings 200 yd. apart, so as to block off the coal in sections or panels measuring 300 x 600 ft. This will have a tendency to drain the gas from the coal before the panels are worked. In this plan, roomnecks can be turned, but the rooms should not be opened or widened out until the butt headings, in each section, hole through into the return airway above. Both on the main slopes and on the cross-entries, the center entry is made the haulage road.

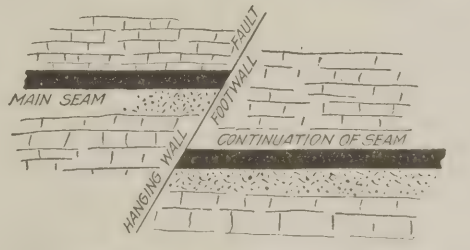
In working out the coal on the retreating system, the work should be started on the inby section at the boundary. No pillars should be drawn, in any of the rooms, until all the rooms in the block are finished, when the room pillars and entry stubs should be drawn back in regular order and that section closed. If the triple-entry system is employed, as here suggested, not a door will be required on any haulage road.

In the operation of a gassy mine, let me suggest that electric cap lamps should be adopted and safety lamps used only for testing for gas, by the firebosses. I would recommend the use of the cap lamps approved by the Bureau of Mines, as soon as gas appears.

The suggestion of duplicate fans being provided is good; but, in my opinion, that is hardly necessary where the fan is operated by a steam engine. Under no conditions would I approve the use of an electrically driven fan for the ventilation of a gassy mine. Such a fan may be thrown out of commission by a thunder storm.

Since every mine must be operated in compliance with the state mining laws, it is important for a mine foreman to consider carefully the requirements. He must think twice before starting operations. Where a seam is liable to generate gas, it may happen that a mine foreman will get what the miners call a "lead-pencil mark," and still be able to operate his mine and avoid serious difficulty, in a seam dipping only 6 per cent. from the surface.

No gas may appear to cause trouble, for a long period of time and, then, the foreman may get a pencil mark that will cause him to sit up and consider. The longwall method of mining, when this can be applied, affords the best facilities for ventilation and not much difficulty will be experienced with the gas, only the circulation must be sufficient to comply with the mining law.



In closing, let me say that at this time, when miners are "going over the top," both in the purchase of bonds and the production of coal, it is more than ever important that they be provided with good air when working in the mine and given every opportunity to do their utmost in the winning of the war.

Farr, Colo. Robert A. Marshall.

Locating the Coal Beyond a Fault

Letter No. 1—From the description of the fault given by "Superintendent," in the inquiry in *Coal Age*, Oct. 24, p. 797, there is no doubt in my mind but that this is a reverse fault.

What is known as a "reverse fault," in geology, is one in which the hanging wall has slipped upward on

ILLUSTRATING A "REVERSE FAULT"

the footwall. The movement has taken place as the result of enormous pressure that has pushed the strata forming the hanging wall and caused it to slide upward over the footwall, along the line of fracture. Such a fault is sometimes called a "compression fault."

What leads me to conclude that this is a reverse fault is the fact mentioned regarding the appearance of the strata at the line of fault. It is stated that the strata had apparently been subjected to a tremendous pressure, as the rock there is much broken. That is just the condition in a reverse fault. The strata are much crushed along the line of fracture, making it difficult and, at times, impossible to identify any of the layers.

As a rule, there is generally a thinning out of the seam at a fault line, and the strata often show an inclination in the direction in which the slip has occurred.

I agree fully with the suggestion made in the reply to this inquiry, that the coal struck in the two boreholes belongs to the "X seam," and that if the holes had been sunk a few feet deeper they would have found the "Y seam." I would say that the throw of this fault is from 45 to 47 ft., as has been already suggested.

Tomhicken, Penn. Joseph Lawrence.

Justice to the Miner

Letter No. 5—Some time ago there appeared in *Coal Age* [July 6, p. 29] the record of a coal miner who loaded 23 tons of coal a day, which was his average for an entire month of 22 working days. The statement led to a discussion that showed what can be accomplished by a good patriotic worker where the conditions are favorable. Whether or not that was the case in the instance mentioned the record was a good one.

However, in justice to many miners who are unable to make such a record, it must be remembered that many conditions exist in the mine that govern and control the possible daily tonnage of the miner. While some miners will shoot and load a large tonnage even where conditions are not particularly favorable, there are others who will load little more than half of such tonnage, under the same or even better conditions.

Much will depend on whether the mine is worked by machine or the coal must be mined with the pick. At times, the coal is already mined and all the miner is required to do is to load it into the cars. The thickness of the seam and the quality of the coal are also large factors in loading a big tonnage. Where the coal is a good thickness and clean and the car supply is ample it is not difficult for an experienced miner to duplicate the record mentioned. On the other hand, in thinner coal, or where the seam contains binders or other impurities that must be separated before the coal is loaded into the cars, the best miner cannot equal such a record.

Big Records Not Frequent in Pick Mining

Large daily records are difficult and quite uncommon in pickwork, while in machine mining and when drawing pillars under favorable conditions, it is nothing extraordinary for a good miner to load a big tonnage. Only a few days ago, a miner working in a 6-ft. seam having one binder loaded 16 cars holding 1½ tons each, which made a record of 24 tons, but that was in pillar work. At another time, I observed a miner make a record of 25 tons, in a single day, loading coal that was already mined.

As I have stated, it is evident that the conditions under which a man is working are a large factor. It would certainly be impossible to make a big tonnage in a low seam or a thick seam with binders and impurities that must be removed. When a man loads 23 tons of coal a day, he has no time to clean the coal, and he must have plenty of room to move around quickly. He must also have one or more cars on hand in his place all the time.

Strange as it may seem, loading a big tonnage does not depend so much on a miner having the coal down and ready to load, as on his having one or more cars in his place ready to be loaded. A good miner will seldom keep a driver waiting, whether his coal is down and ready to load or must be mined, as he plans his work according to the cars he has to load. If an empty car is standing in his place all the time, there will always be a load ready for the driver or motorman to take out when he comes.

Let me say, here, that the operator and the miner alike are gainers when the foreman sees that every working place has a car in it ready to load. When a load is taken out, an empty should be set in its place. But when a miner has his coal down and ready to load and there is no empty car in his place he ceases to work and both the miner and the operator sustain a loss.

It is true that many miners will shovel their loose coal back out of the way to make room for more, while waiting for cars; but this means performing double work and is a loss in efficiency. No miner can load the same large tonnage when he must do this. If the car is ready in his place, the loose coal is loaded into it at once, and the work is not impeded by handling the coal twice. Every miner will load an empty car as quickly as possible, in order to get it out of his way; but when no car is on hand, he works more leisurely.

Thomas, W. Va. EXPERIENCE.

Letter No. 6—Coal miners, today, are confronted with the greatest, most vital, and most important task on which the fate of the world depends, and I want to say most nobly are the miners of this country responding to the call and demand made on their patriotism. With depleted ranks, they are doing splendid and remarkable work in keeping up the production of coal to its present standard.

To the earnest onlooker, it appears as if the great body of coal miners are falling into line in military order, the employees at each colliery forming a company, while the combined forces of a large coal company, operating many mines, constitute a regiment. The superintendent is the major in command, while each mine foreman is appointed to the duties of captain, and all the assistant bosses are his lieutenants and training officers. The miners themselves are the rank and file that form the great service army on which the fate of the world depends. In charge of this great organization is Fuel Administrator Garfield, who is the commander in chief.

While the work of the miner as compared with that of the soldier at the front is vitally important, his sacrifice, in contrast to the sacrifice of those who have answered the draft call, is as the light of a candle to that of the sun. But the fighting army at the front and the industrial army at home are mutually dependent on each other. Without the product of the miners' work, the armies would be helpless; and without the supreme sacrifice of the soldier, the miner would shortly experience days of tyranny equal to those witnessed in Rome in the time of Nero.

Problem of the Production of Coal Growing in Importance

As the war continues, the question of ultimate victory grows in assurance, while that of the needed production of coal is a matter of some concern. The problem is how to increase production with an ever-lessening number of men. Failure to meet this situation would mean both disaster to our army and suffering in numberless homes the coming winter.

However, the noble response of the great body of miners is a sufficient reply to the country's need. They declare as follows: "As a large service army, the miners will not prove false to the trust reposed in them; we will not lose work without reason and gamble our liberty for the lives of our boys, in this hour of the country's need."

Let us strive to introduce into all the mines the same spirit that animates the men in service on land or sea. No sooner does a soldier or sailor fall sick or become disabled than his place is filled by a volunteer whose thought is not for himself but for his country. When the miner has the same desire to keep the coal moving, and is ready and willing to jump into any place where he can serve best, then and only then will we be living up to the patriotism that we inherited from our forefathers, who fought for the freedom of America.

Today, a few districts are falling short of their maximum output, and it is the duty of men in those districts who are not engaged in Government work to heed the call of the colliery whistle in the morning, which is like the bugle call to arms, and volunteer their service for the sake of their country and the freedom they enjoy. Like our boys in France, let us go to our work in the mines singing and filled with the same enthusiasm, and showing the same American spirit, which is the promise of victory. JOSEPH R. THOMAS.

Plymouth, Penn.

Letter No. 7—I have been following closely the numerous references, in *Coal Age* and in the daily press, to the attitude and disposition of the miner in respect to the war. For the most part, the merry chorus has been hammering the miner and calling him to account for his seeming disloyalty. Many of these remarks and comments do a great injustice to our miners as a class. We Americans are too prone to place the blame for conditions before we have carefully weighed the evidence.

That there is intemperance in the coal regions cannot be denied, but it is also true that the same condition exists in other great centers of industry. Compare, for a moment, the workers in the mines with those engaged in building ships. No protest is heard when the report comes from the shipyards showing that 185,000 rivets were driven on Saturday and only 85,000 on the following Monday; and yet the work of shipbuilding is as important, today, as that of mining coal. Failure in either case cannot win the war.

CONDITIONS IN THE ANTHRACITE REGIONS WHERE FOREIGNERS OUTNUMBER AMERICANS

Glance for a moment at the conditions existing at present in the coal regions. Some years ago the foreigner was induced to come here and go into the mines. It was the hope of operators that coal would be produced at a cheaper rate than that paid the American miner. The result is that the foreign miner now outnumbers his American coworker. It is not always the case that the sympathy of these foreigners is with our cause, although that may not be altogether his fault, which is often the case. A large majority of them cannot speak and much less read the English language. Their knowledge of conditions must, therefore, be obtained through an interpreter, who is always in a position to instruct and guide them according to his own inclinations.

A recent case in hand is that of a certain local in which the Americans were outnumbered by the foreign-speaking miners to such an extent that many of the former ceased to attend the meetings. The foreigners were instructed by an interpreter who cared nothing for American army success, but much for American money. The result was that a vote was secured that had the effect to restrict the production of coal in that locality. This was shortly after corrected by the union officials in the district; but, in the meantime, the miners lost much time and needed money.

Again, there can be found, in all coal regions, little executives who lack vision. Instead of inspiring their men they retard production by the "swashbuckling" attitude that was so common in the coal fields before 1902. To curse men and to attempt to make them work faster by threats may succeed for a brief period, but in time such methods will cause rebellion.

As a boy, I remember the banner carried by the miners, at my home, in their first union parade. The banner was inscribed "Gomer Jones, our First Organizer." Mr. Jones organized his men by using the whiphand over them; and a large proportion of our foreign-born miners are under the same control. Such are the conditions that affect the loyalty of many of the workers in our mines, today.

INFLUENCE OF ITALIAN MINERS IN RECENT STRIKE IN SCHUYLKILL COUNTY

Let me refer, here, to the recent struggle in Schuylkill County where the Italian miners were willing to work, because the war had been made real to them. We must make the war real to all our foreign miners, particularly those who cannot read our papers. Our greatest chance for doing this is through their children. The children of the foreigner are, almost without exception, American to the core. As schoolboys and girls they are our best students, and through them we may hope to reach their parents and the boarders in their homes.

Foreign-speaking miners who have boys in the service should be induced to wear their service pins while at work. At each breaker building, slope or shaft, should be posted in a conspicuous place, a list of the boys who have answered the call to service. Much could be accomplished if "Colliery nights," at the local movie theater, could be arranged. At such times, the official films of the United States could be shown and explained in the different languages, in a manner to bring the war home to the men.

In closing, let me give one more proof that the miner is not of the tippling sort that many regard him. The average miner is self-reliant, able to act for himself and industrious. He longs to reach the open air when his day's work in the mine is done. It is this class of workers that find no trouble in securing work at the large factories and plants, who are in sore need of men.

People who are unacquainted with mining conditions little realize the risks taken by miners in their daily work. Men are gassed every week in the mines of Pennsylvania. These and other conditions have made them bold and fearless. It is not claimed that the miners are perfect. Many of them have not as yet caught the vision of world democracy; but for that they are not wholly to blame.

Let us do the miner justice and give him every encouragement and assistance to make him the capable worker and loyal assistant for which he is fitted. In other words, let's boost for more coal by boosting our fellows who get it out, for on them we must depend.

Jeddo, Penn. PATRIOT.

INQUIRIES OF GENERAL INTEREST

Cost of Upkeep of Mine Cars

Observation in the mining regions shows that there are, at the present time, a great number of cheap and inferior mine cars being thrown onto the market, as the result of the stringency placed on the manufacture of cars and other mining equipment by reason of the war. Many mine officials are buying these cars for use in their mines, either ignorant of or ignoring the fact of their inefficiency.

At this time when coal must be produced in greater quantity than ever before, the efficiency of all mine equipment is of the greatest importance and should have equal consideration with that of producing a large output of coal. Not only this, but the fact should be noted that the future of the coal industry is being impaired by the installation of inferior equipment.

Any man of ordinary intelligence who will stop to think for a moment will realize that the difference in cost between a good mine car and a makeshift is so slight as to bear no comparison with the gain that would result from the employment of good mine cars and the best possible grade of other equipment. A cheap mine car is a source of constant expense for repairs, to say nothing of the frequent delays and consequent loss, by reason of wrecks and breakdowns, caused either by broken drawbars, split planks, broken or sprung bolts, wornout wheels and, last but not least, bent or broken axles.

System in Recording Cost of Repairs

In this connection, I am moved to ask if any of the readers of *Coal Age* have available records of accurate costs of the upkeep of either plain- or roller-bearing mine cars. Also, whether they have any figures on the cost of repairing cars in a haphazard or makeshift fashion, as compared with the cost of keeping them in proper condition, by employing a regularly appointed mine-car repairer who understands his business and can systematize the work and lessen the cost for repairs and upkeep of all equipment.

Allow me to instance the case of a mine, in the metal country, that has recently come to my knowledge. The mine had in use only 230 mine cars or "trams," as they are called out there. With this equipment, they saved slightly more than $5000 in a year's time, by placing a competent man in charge of their repair work and upkeep, including the oiling of the cars.

Formerly, at this mine, the company had employed what they describe as a hit-or-miss method where no system was used and repairs were made by anyone and at any time that was most convenient for that purpose. It goes without saying that there was no selection of proper material, no duplication of parts, nor any systematic arrangement; but each car presented a proposition all its own and was patched and mended accordingly.

The most casual observation shows that practically every mine has more or less cars laid up for minor causes, such as I have mentioned. Frequently a car will be laid aside for days at a time, owing to some slight cause that could be remedied in a short time and the car again put in use. This would not happen if a man were placed in charge and made responsible for this work. His daily report to the superintendent or manager would show what was being done and keep that official in touch with conditions that need his constant attention if there is to be no interruption in the daily production of the mine.

Most of the repairs on mine cars are a simple matter. A broken plank needs to be taken out and a new one put in its place; an axle has to be straightened, or its fastenings made more secure; wornout wheels must be replaced by new ones; a broken drawbar mended; or numerous other similar repairs require to be made if the rolling stock is to be kept in good condition.

This work should be done as soon as the first signs of trouble appear; but, around most mines, minor repairs are postponed until something serious happens as a result. The condition is illustrated by the old ditty that runs, "For want of a nail the shoe was lost; for want of a shoe the horse was lost; for want of a horse the rider was lost; and all for want of a horseshoe nail." So it is with the many little repairs that are continually needed by mine cars.

In urging the discussion of this question and the submission of comparative costs of haphazard and systematic methods of dealing with repair work in mines, let me suggest that the running gear of a mine car should receive special attention. Suitable thrust washers should be provided to take up the play caused by wear, which will thus be reduced to a minimum. Wheels should be oiled regularly, a plain-bearing wheel requires to be oiled at least four times a week and a good roller-bearing wheel every few months. Until this question is more thoroughly understood and given attention, haulage costs in mines will be excessive and the production of coal will suffer. Let us have comparative cost-sheets that will teach their own lesson. OBSERVER.

Pittsburgh, Penn.

The proposition presented in this inquiry has not been overstated in respect to its importance to the economical production of coal. Cost accounting in respect to supplies of material and labor in coal mining is no greater in importance than is the cost of upkeep or maintenance of haulage and other equipment. Immense good will result from the practical discussion of these questions and the submission of comparative cost-sheets, as suggested by the correspondent. *Coal Age* will gladly give space for the publication of such data, which will prove most beneficial to the coal industry in the present need of the country. We hope for a generous response to this timely inquiry.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—How many aircourses 5 x 4 ft. will be required to give the same sectional area as one 8 x 10 ft.? Which will pass the more air, and why?

Ans.—The sectional area of each of the smaller airways is $4 \times 5 = 20$ sq.ft., while that of the larger airway is $8 \times 10 = 80$ sq.ft. The number of smaller airways required to give the same sectional area as the larger ones is, therefore, $80 \div 20 = 4$ airways.

Assuming that each of the four smaller airways has the same length as the longer airway, and that the unit pressure producing the circulation in each of the airways is the same, the larger airway will pass the larger quantity of air. The sectional area, length and unit pressure being the same in each case, the quantity of air in circulation will vary inversely as the square root of the perimeter. In other words, the quantity ratio is then equal to the square root of the inverse perimeter ratio.

In this case, comparing the circulation in the four small airways with that in the large airway, the sum of the perimeters of the four smaller airways is $4 \times 2 (4 + 5) = 72$ ft., while that of the larger airway is $2(8 + 10) = 36$ ft. The perimeter ratio is therefore, in this case, $72 \div 36 = 2$. The larger airway will therefore pass $\sqrt{2} = 1.414$ times the quantity of air passing in the four smaller airways under the same pressure.

Ques.—If a water gage, placed in a door 4 ft. 6 in. high and 5 ft. wide, shows a reading of 2.7 in., what is the total pressure on the door?

Ans.—A water gage of 2.7 in. indicates a pressure of $2.7 \times 5.2 = 14.04$ lb. per sq.ft. The area of the door, in this case, is $4.5 \times 5 = 22.5$ sq.ft. The total pressure on the door is, therefore, $14.04 \times 22.5 = 315.9$ lb.

Ques.—With a water gage of 0.4 in. we are producing 35,000 cu.ft. of air per min. What quantity will we get with a water gage of 0.9 in.?

Ans.—For the same condition in the mine or airway, the quantity of air in circulation varies as the square root of the pressure or water gage. In other words, the quantity ratio is equal to the square root of the water-gage ratio. In this case, calling the required quantity of air circulated by 0.9 in. of water gage x, we have

$$\frac{x}{35{,}000} = \sqrt{\frac{0.9}{0.4}} = \sqrt{2.25} = 1.5$$

$$x = 1.5 \times 35{,}000 = 52{,}500 \text{ cu.ft. per min.}$$

Ques.—What should a mine foreman do when he employs a new man?

Ans.—When employing a new man, the foreman should examine his credentials to ascertain where he has worked previously, and find out what are his experience and capabilities. Before permitting him to proceed to work, the foreman must be assured that the man is able to take care of himself in the mine and instruct him in regard to the rules and regulations that must be observed.

Ques.—What are the principal causes of mine fires in coal mines, and what precaution should be taken to guard against them?

Ans.—Mine fires occur most frequently as the result of lack of care in the work of blasting. Frequently, a gas feeder will be ignited by a blast and will not be discovered until the men enter the mine for work, or the fireboss makes his morning examination. By that time, the coal has become ignited, and the fire may have gained considerable headway. To avoid this condition, where blasting is done in mines generating gas, it is necessary that an examination be made following the firing of shots in the mine.

In mines where the coal is highly inflammable, and much dust accumulates in the working places, there is liability of spontaneous combustion taking place, especially if the fine coal and slack is stored in the waste. To avoid this difficulty, all fine coal and dust should be loaded out of the mine.

Many fires occur in mines owing to the careless use of open lights, or from the improper wiring of electric installations. To avoid such happenings, mine stables, tool shanties, and all other buildings should be constructed of noninflammable material. Concrete should be used wherever this is possible. Strict regulations should be enforced in regard to the use of open lamps and torches, which should never be permitted in mine stables or where hay or other combustible supplies are being handled or taken into the mine. All electrical installations should be made by a competent electrician and safeguarded in every practicable manner.

Ques.—What method of ventilation lessens the danger of an explosion and reduces friction? State your reasons.

Ans.—Splitting the air current in such a manner that each district of the mine will be ventilated by a separate air split reduces the danger of an explosion of gas or dust occurring in the mine, because the quantity of air passing in each district can then be regulated according to the need. Each district will be supplied with pure air direct from the main intake airway, instead of being ventilated by the return air from other districts, which would be more or less laden with gas.

Also, splitting the air current reduces the velocity of the air at the working face, and there is less danger of the flame of safety lamps being blown through the gauze. Should an explosion occur in one district, it is not as liable to be carried into another district as when the entire mine is ventilated by a single air current.

Splitting the air current reduces the frictional resistance by reducing the velocity with which the air is traveling. As a result, a larger quantity of air is circulated with the same power.

COAL AND COKE NEWS

Harrisburg, Penn.

Although the new anthracite wage scale, the highest ever paid, has been in effect only since the first of the month, there is already a rush of men back to the mines from munitions plants and other industries from all over the East. It is believed with the war nearing its close, there will be a continuous rush to the collieries and that by the beginning of next year the operators will again have nearly their normal forces. Since the outbreak of the war 30,000 men have left the coal regions.

Uniontown, Penn.

Coal and coke production in the Connellsville region is believed to have touched its lowest level by reason of the influenza epidemic for the week ended Nov. 2. Figures issued by Manager of Production W. L. Byers place the week's coal output at 655,227 tons, 30,925 tons below that of last week and a drop of 94,157 from the record production of Oct. 12. Conservatively the influenza epidemic in three weeks' time cut 200,000 tons from the output of this region.

An apparent listless market for coal for fuel purposes only has resulted in the machinery of the production campaign here being concentrated on byproduct coal and beehive coke. An inquiry by a local brokerage agency for fuel coal to several consumers in widely separated sections brought back the reply of a surplus stock, and other brokers make similar reports.

Much significance in that respect is attached in some quarters to a recent order of the railroad administration substituting open-top cars for box cars by the Pennsylvania Railroad company to team track loaders in this region. The order brought a strong protest from operators of that class and the date of its effectiveness was advanced to Nov. 12.

The railroad order cuts 75c. per ton from the fixed price of the team trackers' product and means their virtual elimination from the industry, they say. To the fixed price of $2.35 a ton the fuel administration permitted 75c. per ton to be added to cover the expense of hauling to the railroad siding. The order places the team tracker in the same class as the tipple loader, but the former class of operator must now bear the expense of hauling from the mines to the railroads.

The team trackers openly charge that the order was made at the instance of the fuel administration because there was no longer any great demand for coal of that quality. That charge has been denied by the regional fuel administration and the Pennsylvania Railroad company accepts responsibility. It will without doubt discourage production by the team track loaders.

Charleston, W. Va.

With more men available for work in the mines as a result of an improvement in the influenza situation in the district, and with the Baltimore & Ohio able to furnish more cars than has been the case for the last few months, production was increased somewhat in the Fairmont region during the week ending Nov. 2. So long, however, as cars are placed after the usual hour for beginning work, it will be difficult for the mines to mine coal to their capacity and to load promptly. There appears to have been a pronounced improvement in the power supply for the mines of the region during the last few days.

The hold the influenza epidemic has on the mines of the Upper Potomac region has not prevented an increase in production during the last week of 7 per cent. over the preceding week. The total output was 39,325 tons. In the western Maryland field there was an even greater percentage of increase, amounting to 26 per cent. There have been frequent appeals for more physicians and nurses in the Upper Potomac region as a means of combating the further spread of the influenza.

October coal production in the Pocahontas and Tug River districts amounted to 2,034,245 tons. Of the total tonnage produced 1,829,242 tons were shipped, that being the largest record of the present calendar year. When the fact is considered that 8000 miners were doing the work usually done by 13,000, and that there was a further hindrance of operations through influenza, both as to the mines and as to the railroads, the performance is considered notable.

Mines in the Thacker field of West Virginia suffered heavily from the blighting effect of influenza during the week ending Nov. 2. It is estimated that there was a loss in production for that period of not less than 45 per cent.

The influenza epidemic made itself more severely felt in the New River and Winding Gulf districts last week than at any time during October, other unfavorable circumstances also combining to limit the amount of coal mined. As nearly as can be determined the influenza was responsible for about 15 per cent. of the loss in the New River and Winding Gulf fields but late placements also affected production. In addition to such trouble some of the mines found it difficult to secure enough power to operate during a part of one day last week.

Tonnage mined in the Kanawha district during the week ending Nov. 2 was 18,271 less than during the week ending Oct. 26, only 162,097 tons being mined as against 180,368 for the preceding week. Practically the entire decrease was due to labor shortage, the loss in hours from that cause being 1013. Sickness among the miners of course kept many men out of the mines. Power was low for a day or so last week and that also affected production. That the car service was satisfactory is shown by the fact that only 36 hours were lost from that cause.

Birmingham, Ala.

Coal production in Alabama for the week just past will show much improvement over the output for the two weeks previous. The epidemic of influenza, which was demoralizing to the operators and the men, has spent its force and is on the wane, according to the city health officer of Birmingham. There are more men at work during the present week than at any time since the middle of last month, and the output figures will be affected accordingly.

Production Manager Sellheimer is confident that from now on the coal production will show marked increase, and that the losses of the past few weeks will be recovered. Outputs equal to those of July and August are expected within two weeks, and when developments now under way are ready for operation, still further increases in production are looked for. Railroad Administration officials are informed that there will be a larger output at the mines from now on, and are redoubling their efforts to supply the demand for cars with an adequate number.

Coal producers in the western part of Jefferson County and in Walker County feel somewhat better over the prospects of an early service on the Warrior River. In addition to the equipment formerly owned by the New Orleans and Alabama Transportation Co. and that of the Pratt Consolidated Coal Co. and the DeBardeleben Coal Co., there will be considerable new equipment placed in the service.

Coke supplies of the Birmingham district are picking up a little as coal production increases. A. H. Carpenter, coke production manager, is surveying the entire district, and is working on plans to bring about a better and clearer output of coke in the Birmingham district.

Victoria, B. C.

An increase of 75c. a ton in the selling price of coal in British Columbia was authorized by Nichol Thompson, Pacific Coast representative of the Fuel Controller, on Nov. 1. Coal for domestic uses, therefore, now costs $9.75 a ton in this Province. The further advance is the direct result of the raise of 75c. a day in the wages of the coal miners of British Columbia, which was demanded by them and granted by the officials of the Fuel Control Department a few weeks ago.

Vancouver City proposes to appoint a Fuel Administrator under the terms of an order-in-council passed by the Dominion Government authorizing both Provincial and Municipal officers to work with the Fuel Controller in fixing prices, regulating distribution and in the discharge of the many other duties of the department. Up to the present the Provincial Government has not named a Fuel Controller for this section of Canada, but Mr. Thompson is acting in the interim and it will be the duty of Vancouver's representative to protect the citizens of that city against unduly high prices and, in the event of a shortage of fuel this winter, which does not seem likely to occur, to see that the available resources are fairly allocated.

The total production of coal for the Province of British Columbia for the month of September was 164,460 tons, or a decrease of 75,777 tons as compared to the August output. This is the first month of this year that has shown a decline, and it is to be explained to a large extent by the month's strike of the miners of the Fernie and Michel collieries in the Crowsnest Pass Field. This is responsible for a loss of at least 50,000 tons, the August return from these mines being 78,971 tons as against 17,784 tons for the month under review. There also should be taken into consideration Labor Day, five Sundays, and a 30-day month, as well as the Nanaimo accident, in which some sixteen miners were lost when the hoisting cable in No. 1 shaft, Protection, Western Fuel Co., broke and let a descending cage fall.

Seattle, Wash.

A great scarcity of men is being experienced in the coal mines of Washington, and a systematic search for those who have left the occupation in recent months to enter other work is being made by officials of organized labor and where found the miner will be induced to return to the coal mines. Between 1300 and 1500 coal miners have left the mines in this state since the first of the year, and many of these have gone into shipyards and other industries where the pay is larger. But it is pointed out that now that the Macey board has in its adjustment of the shipyard wage scale throughout the country virtually lowered the wages here, that coal miners at their pay are now able to greatly exceed the earnings of the shipyard worker and some miners may return on this score.

The withdrawal of 1500 men from the coal mines of the state has been seriously affecting coal output, and it is stated that estimates since July 1 are being revised with this element given due consideration; and the conclusion reached by operators is that Washington will not exceed its output of last year and may fall considerably below. To keep pace with consumption the mines of the state must produce 5,000,000 tons of coal this year. Last year the production was a little more than 4,000,000 tons.

Martin J. Flyzig, president of District No. 10, U. M. W. A., has received a list of over 200 coal miners of the state who have left the mines for other employment and his organization is now making a systematic canvass to locate these men. It will be pointed out to them that it is a patriotic duty to return to the mines and failure to induce them to take up this work again will result in their names being returned to the Government. What further action the Government will take is not indicated in the letter sent by the Government employment bureau, but it is asking that all details regarding each case of refusal be secured.

Edmonton, Alta.

C. W. Peterson, Deputy Fuel Controller for Canada, who has been traveling through the West looking into the coal situation, states that there is no cause for panic. He held a conference with the coal dealers of Winnipeg and was gratified to learn of

the manner in which the people of that city were taking to Alberta coal, the prejudice which lately existed against it having been removed by the publicity campaign and the satisfactory results obtained from its use.

The normal importation of anthracite to the head of the Lakes is about 500,000 tons, but the allotment this year is reduced to 275,000 tons, out of which Western Ontario is allotted approximately 70,000 tons, which would leave 205,000 tons available for Manitoba and Saskatchewan.

The tonnage of anthracite to be replaced by Alberta lignites is about 270,000 tons and up to Sept. 1 increased shipments had been made from the Alberta lignite mines to Manitoba and Saskatchewan amounting to 267,000 tons, so that, allowing for the difference in heating power on a basis of three tons of lignite to two of anthracite, the situation was well in hand.

As increased shipments of lignite to points in Alberta for the period up to Sept. 1 were 112,000 tons as compared with last year, it is clear that the basis on which the winter is started is equal to that of last year. Everything, however, depends on the normal winter output of lignite being maintained in Alberta. The present epidemic has had the effect of closing a number of mines, notably in the Drumheller district. If this condition should last for any considerable period the effect may be very unfortunate, as the prairie country is absolutely dependent on current shipments from Alberta. Early in the season complaints were received from the fuel administrators of Manitoba and Saskatchewan to the effect that the quality of shipments of lignite was in some cases far below standard and that inferior grades had been offered to the public under false designations. This led to regulations being prescribed by the Fuel Controller and ratified by order-in-council establishing a system of inspection at the Alberta mines.

PENNSYLVANIA

Anthracite

Hazelton—Although handicapped by a 25 per cent. shortage in labor as a result of wartime conditions, the G. B. Markle Coal Co., largest anthracite producer in the world, has exceeded its former record of 1,500,000 tons mined in the past fiscal year, which ended Nov. 1. The output is nearly 100,000 tons more than during the previous twelve months.

Alden—Because all the shaft engineers are ill with influenza the Alden Coal Co. was unable to operate its colliery on Nov. 7, but is making an effort to have sufficient number of engineers on hand to get the colliery in operation as early as possible. The influenza is playing havoc with the employees of this company, as out of 750 employees only 292 reported for work on Nov. 4. It is thought that many of these were idle, because of the illness of themselves or of that of some member of the family.

Bituminous

Uniontown.—Reports made to the fuel administration by operators show that during the period of the saloon closing order, the averaged output per man was increased one ton per day. Another operator not affected by the epidemic reported a normal labor supply the day after pay day, a most unusual record in this region.

Pittsburgh — The influenza situation in central and western Pennsylvania is improving rapidly and the reduced outputs of the mines increasing. The betterment is slow, however, due to the weakened condition of the men following the disease. It will probably be at least two weeks before all the men are at work and able to do a normal day's work.

WEST VIRGINIA

Bluefield—With the installation of additional machinery, the Roberts Coal Co. at Glamorgan is making much progress in its efforts to increase production. R. R. Roberts is the general manager.

Bluefield—A new opening has been driven by the Norton Coal Co. at Norton into a 6-ft. vein. Work is progressing on the grading for a new tipple. The company has also had built 25 additional dwellings for miners.

Norton—As a means of increasing its output the Hawthorne Coal Co. has put up a new tipple. Because of the large number of additional miners needed, it has also been arranged to build 60 houses, 50 of which have been completed. M. Presley is the superintendent in charge.

Morgantown—Fully 50 per cent. of the miners in the Monongalia field were off during the greater part of the week ending Nov. 2, with influenza, according to a personal investigation made by C. F. Ice, chief inspector in the Fairmont region. As a result operations were materially crippled in that section.

Wheeling—N. J. Virgin and J. J. Herbert, well known mining men of Moundsville, W. Va., formerly with the Parrs Run mine of the Mineral State Coal Co., have leased and will operate the Schaub mine, owned by the Schaub Bros. & Howard Coal Co. The name of the new firm will be the Virgin-Herbert Coal Co.

Bluefield—Extensive improvements have been made by the Virginia Iron, Coal and Coke Co. Not only has a large and modern tipple been put up, but many new houses have been erected for miners. With the installation of mining machines the company is also arranging to speed up production as much as possible.

Dunbar—A new colliery is being built by the Stonega Coal and Coke Co. at Dunbar, on the Roaring Fork Division of the Interstate R.R. The mines are to be electrically equipped throughout, all machinery having been purchased. With an ultimate capacity of 1500 tons a day, the company expects to begin the shipment of coal early next year. The general manager of the company is R. E. Taggart.

Elkins—Among the newest operations at Adrian, which has become one of the principal coal-producing points on the Coal & Coke during the last year, is that of the Miller Coal Co., whose plant was only recently completed and put in commission. The plant includes a modern tipple. About two cars of coal a day are now being shipped, but this will probably be increased as soon as the plant is in full operation.

VIRGINIA

Clinchfield—The International Coal Products Co., of which Charles H. Smith is president, will build a plant at this place to distill coal to recover totuol, benzol and other coal tar products. The Government will purchase the distilled products. The Clinchfield Carbocoal Corporation will operate the plant.

INDIANA

Boonville—William R. Tapper wishes to develop a strip mine and is seeking a right-of-way from the Southern Railway Co., two miles south of Boonville. Condemnation proceedings have been brought by Mr. Tapper against the Big Four Coal Co. and adjacent property owners to secure the switch from the Southern Ry. The Big Four Coal Co. is resisting the right-of-way.

ILLINOIS

Bethalto—The reopening of a mine here by a company composed mostly of residents of East St. Louis has disclosed that there is a vein of sufficient thickness to be commercially profitable, and of unusually high quality. State authorities have found that the coal tests four points higher than other Illinois coal for steam and heating purposes. The vein has a roof of limestone.

Shelbyville—The Tower Hill Coal mine at Tower Hill, near here, which has been operated for a year under the stimulus of high prices, has now been closed down permanently. Officials of the company say they have been operating at a loss for several months and working conditions have become dangerous because of the settling of the earth. Most of the 130 miners who have been employed in the mine will move to other localities.

Belleville—For the purpose of increasing the production at the Avery mine here, a joint production committee has been created, composed of three representatives of the company and three representatives of the miners. The company representatives are John Green, Carl Heidinger and John Meyer. The miners' representatives are Peter Boatman, Joseph Lawton and Herman Weber. Any question upon which the committeemen are unable to agree will be referred to the Fuel Administration.

TENNESSEE

Briceville—The tipple and boiler house of the Cross Mountain Coal Co. of this place caught fire on the night of Nov. 4 and burned down completely. This forces the discontinuance of loading from the Cross Mountain and Volunteer mines. A temporary tipple is being built and it is hoped that coal will soon be dumped. The tipple was a complete loss, together with its equipment. The boilers were not seriously damaged although the building was a complete loss. Steam and power were in use within 18 hours after the fire. The Cross Mountain Coal Co. expects to erect a modern tipple to replace the one destroyed.

Personals

James L. Brown has been appointed Overman at No. 7 Mine, Canadian Collieries (D) Ltd., vice Robert Brown.

Arthur C. James, statistician of the Pennsylvania Department of Mines, has been appointed to Chief Clerk of the Department. **M. H. Irwin** has been appointed to succeed Mr. James.

John G. Barbour, of Uniontown, Penn., has resigned as fuel director for Fayette County on account of the press of other work. Mr. Barbour's successor will be named from a list submitted by him at the request of Administrator Garfield.

Floyd W. Parsons, editor of "Coal Age," is one of a party of trade paper editors and publishers which sailed on Oct. 26 for England on a tour of inspection of British industry under war conditions. The trip, which is under the auspices of the British Government, will take about six weeks and will include a visit to the battle areas in France.

Sheldon Smillie, at one time superintendent for the Vinton Collieries Co., at Vintondale, Penn., and then assistant and later chief engineer for the Indiana Division of the Rochester & Pittsburgh Coal and Iron Co., has been placed in charge of the Pittsburgh office of the Wood Equipment Co. of Chicago. Mr. Smillie's mining and engineering experience make him well fitted to handle the company's product, which consists of the pneumatic rotary dump and other devices for mine car handling and control.

Obituary

Joseph Hanford, who for a number of years was superintendent of the Elkins Coal and Coke Co. at Bretz, W. Va., died Nov. 4 from pneumonia. The deceased is survived by his widow, two daughters and a brother.

Arden L. Talbott, manager and part owner of the Bell Coal Co., which operates a mine at Reynoldsville, W. Va., died Nov. 1 from injuries he received when struck by a trolley car. The deceased leaves a widow and three children.

Cyrus Echard, one of the pioneer coal and coke operators of Fayette County, Pennsylvania, died recently in Connellsville, Penn., aged 71. The deceased several years ago organized the Echard Coal and Coke Co., of which he was preseident. He leaves a son, Dr. Thomas E. Echard, of Connellsville.

Benjamin L. Flynn, general superintendent of the various operations of the Logan Mining Co., of Logan, W. Va., died on Nov. 1 of influenza. Mr. Flynn, who was well known in the Logan County field, is survived by his widow and three young sons. He was a Knight Templar and a 32nd degree Mason.

Coming Meetings

Kentucky Mining Institute will hold its winter meeting Dec. 6 and 7, at Lexington, Ky. Secretary, Charles W. Strickland, Huntington, W. Va.

American Society of Mechanical Engineers will hold its annual meeting Dec. 3-6 in New York. Secretary, Calvin W. Rice, 29 West 39th Street, New York City.

Coal Mining Institute of America will hold its annual meeting Dec. 4 and 5 in Pittsburgh, Penn. Secretary H. D. Mason, 911 Chamber of Commerce Building, Pittsburgh, Penn.

Publications Received

Annual Report of the Department of Public Works of the Province of Alberta, 1917. Unillustrated, pp. 226, 6½ x 10 inches.

Monthly Statement of Coal-Mine Fatalities in the United States, July, 1918. Compiled by Albert H. Fay. Unillustrated, 27 pp.; 6 x 9 inches.

Saving Coal in Boiler Plants. By Henry Kreisinger. Department of the Interior, Bureau of Mines. Technical paper 205. Illustrated, 24 pp., 6 x 9 inches.

How to Improve the Hot-Air Furnace. By Charles Whiting Baker. Department of the Interior, Bureau of Mines. Technical Paper 208. Unillustrated, 20 pp., 6 x 9 inches.

Boiler and Furnace Testing. By Rufus T. Strohm. Engineering Bulletin No. 1. United States Fuel Administration, Bureau of Conservation. Illustrated, 20 pp., 6 x 9 inches.

Coöperative Mining Series Bulletin 22. State of Illinois, Department of Registration and Education; Division of the State Geological Survey. Illustrated; 24 pp.; 6 x 9 inches.

List of Fuel and Petroleum Statistics. Issued by the Statistical Clearing House, Central Bureau of Planning and Statistics, Washington, D. C. October, 1918. Bulletin, 46 pp. The purpose of this bulletin is to show the principal source of statistics on fuel and petroleum. It includes both original and secondary sources and the various offices in Washington from which the tabulations may be secured by properly accredited persons.

Trade Catalogs

The Thew Underground Mining Shovel. Thew Automatic Shovel Co., Lorain, Ohio. Bulletin No. 29. Pp. 14; 8½ x 11 in.; illustrated. Describes and illustrates the essential features of an underground mining shovel.

"Come Again." Crescent Belt Fastener Co., 381 Fourth Ave., New York. Illustrated, 24 pp., 5½ x 7½ in. Treats the subject of belting in a humorous way, and strikes at some of the old-time methods of belt-joining.

Nonpareil High-Pressure Blocks and Cement. Armstrong Cork Co., Pittsburgh, Penn. Booklet. Pp. 20, 5½ x 7½ in.; illustrated. Describes insulating material for minimizing the loss of heat from steam drums, feed water heaters, internally fired and locomotive type boilers, tanks, breechings, etc.

Giant Trucks. Chicago Pneumatic Tool Co., Chicago, Ill. Illustrated, 32 pp., 9 x 12½ in. Catalog No. 344. The chief claim made for these motor trucks is that they operate on low grade fuels. The vital features of construction are described and the specifications for the various models are given in detail.

Coppus Turbo Blower. Coppus Engineering and Equipment Co., Worcester, Mass. Catalog. Pp. 52, 5½ x 8¾ in., illustrated. Describes the Coppus blower for undergrate draft and other industrial purposes, and enumerates the advantages of mechanical over natural draft. Valuable tables and data are given concerning forced draft apparatus.

Facts. The Cutler-Hammer Mfg. Co., Milwaukee, Wis. Booklet. Pp. 8, 8½ x 11 in., illustrated. This booklet, which is printed in two colors, illustrates and describes the Dean valve control and its application to large valves. Special emphasis is laid on the fact that by the application of this control to water mains at strategic points a great deal of the damage caused by bursting water mains may be averted.

Recent Coal and Coke Patents

Mine Door. J. J. Body and M. L. Johnson, Dante, Va., 1,255,697. Feb. 5, 1918. Filed Aug. 15, 1917. Serial No. 186,389.

Grate. W. Fisher, New Orleans, La., 1,255,727. Feb. 5, 1918. Filed Nov. 8, 1916. Serial No. 130,237.

Process of Burning Solid Fuel. O. b. Evans, assignor to United Gas Improvement Co., Philadelphia, Penn., 1,267,646. May 28, 1918. Filed Jan. 3, 1916. Serial No. 69,730.

Discharge Apparatus for Ash Conveyors. A. Girtamer and R. H. Miller, assignor to American Steam Conveyor Corporation, Chicago, Ill. 1,275,015. Aug. 6, 1918. Filed June 25, 1915. Serial No. 36,195.

Mine Car Running Gear. C. R. Waid, Birmingham, Ala., 1,275,188. Aug. 6, 1918. Filed Feb. 14, 1916. Serial No. 78,128.

Dump Car. F. A. McRae, Montreal, Quebec, Can., 1,274,732. Aug. 6, 1918. Filed July 3, 1917. Serial No. 178,518.

Coal Mining Machine. I. Rudai and A. Szarka, Vestaburg, Penn., 1,274,939. Aug. 6, 1918. Filed May 6, 1918. Serial No. 232,923.

Fuel Support for Furnaces. W. J. Kunz, Milwaukee, Wis., 1,274,563. Aug. 6, 1918. Filed Jan. 24, 1917. Serial No. 144,128.

Miners' Lamplighter. M. Hendler, assignor to Dewar Mfg. Co., Wilmington, Del., 1,274,544. Aug. 6, 1918. Filed April 12, 1913. Serial No. 760,629.

Mining Machine. C. E. Davis, assignor Goodman Manufacturing Co., Chicago, Ill., 1,274,516. Aug. 6, 1918. Filed May 10, 1915. Serial No. 26,990.

Coal Pusher. I. Lemay, Sault Ste. Marie, Ontario, Can., 1,275,708. Aug. 13, 1918. Filed Nov. 26, 1917. Serial No. 203,916.

Gas Producer. A. M. Taylor, assignor General Chemical Co., New York, 1,275,789. Aug. 13, 1918. Filed Feb. 10, 1916. Serial No. 77,372.

Fire Box for Locomotives. H. D. Sawyer, Revere, Mass., 1,275,763. Aug. 13, 1918. Filed Jan. 13, 1911. Serial No. 602,432.
